There are 10 banks, with an aggregate paid-up capital of $2,500,000, and average deposits of $3,500,000 to $4,000,000. Ten insurance companies chartered by the state have their headquarters in Memphis, and about 30 companies of other states and countries have agencies here. The city is divided into ten wards, and is governed by a mayor, with a board of aldermen of one member and a common council of two members from each ward. It has an efficient police force and a good fire department. The assessed valuation in 1860 was $18,212,861; in 1870, $24,788,190; in 1874, $29,901,592. The rate of taxation is $1.80 on $100, and the city debt amounts to about $4,000,000. The United States courts for the W. district of Tennessee are held here. The principal charitable institutions are the Leath orphan asylum, St. Peter's orphan asylum, church orphans' home, the colored orphan asylum, and the city hospital. There are 67 public schools, with an average attendance of 2,918 white and 1,565 colored pupils; they are graded, and include a male and a female high school. Four of the Catholic parochial schools are also free, and have a daily attendance of 650 white children. Christian Brothers' college (Roman Catholic), established in 1871, in 1873-'4 had 12 professors and instructors, and 122 preparatory and 37 collegiate students. The Memphis female college is in the city, and the state female college near by. There are 92 private schools and academies. The Memphis library association has 9,000 volumes. Five daily, one tri-weekly, nine weekly (one German) newspapers and two monthly periodicals are published. There are 48 churches, viz.: 11 Baptist (8 colored), 2 Christian (1 colored), 2 Congregational (1 colored), 3 Cumberland Presbyterian, 5 Episcopalian, 2 Jewish, 1 Lutheran, 12 Methodist (4 Southern and 6 colored), 6 Presbyterian (1 German), and 4 Roman Catholic (1 German).

Memphis was laid out in 1820, and incorporated as a city in 1831. During the Civil War, after a naval encounter in which the confederate flotilla was nearly destroyed, the city was taken possession of by the Union forces, June 6, 1862, and was never afterward held by the confederates. In August, 1864, a cavalry raid was made upon it by Gen. Forrest, who entered the town, made several hundred prisoners, and then departed.

MEMPHIS (Coptic, Menô or Menôfer, "good abode" or "the abode of the good one," supposed to refer to Osiris; in hieroglyphic inscriptions, according to some, Mu-en-Ptah, abode of Ptah; in Scripture, Noph or Moph), an ancient capital of Egypt, on the W. bank of the Nile, 10 m. S. of the modern city of
MEMPHREMAGOG

Cairo. Its foundation is ascribed to Menes, the first king of Egypt; it was certainly very ancient, and was the chief capital of the united kingdom of Upper and Lower Egypt. Its situation commanded the S. entrance to the delta, and it was protected by a dike from the inundations of the Nile. According to Dio- dorus, Memphis was about 17 m. in circuit, but probably this included much open ground. It was remarkable for its fine climate and the beauty of the view from its walls. It controlled the inland trade of Egypt, ascending or descending the Nile. It was the chief seat of learning and of religion, the principal place of the worship of the god Ptah, and the chosen residence of the sacred bull Apis, whose temple here was celebrated for its colonnades through which the great processions were conducted. The other great temples were: that of Isis, commenced at a very early period, and completed by Amasis, 564 B.C.; the temple of Serapis, to which was attached a Nilometer, in the western quarter of the city; the temple of Phra or the sun; and the temple of Ptah, the most ancient of all, and the largest and most superb.—Memphis was the seat of successive dynasties, the 3d, 4th, 5th, 6th, 7th, and 8th of Egyptian history, who (according to Mariette) reigned, with one interval of 203 years, from 4449 to 3358 B.C. By the 4th dynasty the great pyramids were built. It was also the capital during the supremacy of the shepherd kings. It suffered severely from the Persians, who avenged the murder of their herald by the Memphisians. They made it the headquarters of a Persian garrison; and Cambyses compelled Psammotik III., the last of the Pharoahs, to kill himself, slew the sacred Apis with his own hand, massacred the priests, and profaned the temple of Ptah. The Persians made it the metropolis of their African possessions, and it continued to be the chief city of Egypt until the foundation of Alexandria, after which it gradually declined, and in the course of ages sunk into such utter decay that its very site, overwhelmed with drifted sand, was a matter of dispute among antiquaries. Modern researches have proved that the village of Mitra- benni or Mitranich, S. of Gizeh, marks the site of Memphis. Its remains extend over many hundred acres of ground, and include ruins of temples and of palaces, and statues, base reliefs, and inscriptions, to the number of several thousand.

MEMPHREMAGOG, Lake, a body of water, about 35 m. long from N. to S. and from 2 to 5 m. wide, situated partly in Vermont and partly in Quebec, Canada. It discharges through Magog river into the St. Francis, and thence into the St. Lawrence. Along the W. shore are several mountains, prominent among which are Owl's Head, Elephants, and the Sugar Loaf; the E. shore presents a pleasing contrast. The lake is studded with islands, and abounds in fine fish. Near its head is the village of Newport, and at its outlet Magog, between which a steamer plies in summer, accommodating the numerous visitors.

MENANDER, an Athenian dramatic poet, born in 342 B.C., died in 291. Alexis, the comic poet, was his paternal uncle, Theophrastus his preceptor, and Epicurus his intimate friend. Little is known of his life. His comedies gained him the patronage of Demetrius Phaleres, and of the first Ptolemy, who invited him to his court at Alexandria; this invitation he declined. His intimacy with Demetrius Phaleres involved him in danger after the expulsion of that statesman from Athens by Demetrius Poliorcetes; and he would have been put to death but for the intercession of Telesphorus, son-in-law of the latter. He is said to have been drowned while swimming in the harbor of Piraeus. The Athenians raised a monument to his memory beside that of Eu- ridipes, and placed his statue in the theatre.

MENANDER, a French author, born in Angers, Aug. 15, 1613, died in Paris, July 23, 1692. After practising law for a short time he became a priest, and lived for a while with Cardinal de Retz, but finally established himself in a house in the cloister of Notre Dame, where on Wednesdays he entertained numbers of wits and scholars. His wit and erudition became celebrated; his quarrels, his social relations, and the epigrams and witticisms which they called forth, are prominent in the literary history of the 17th century. He wrote, among other works, Origines de la langue française (1650), enlarged and published as Dictionnaire étymologique de la langue française (1694); Poëmata Latina, Gallica, Graeca et Italica (1658); and Anti-Baillet (1685). After his death his friends published, under the title of Menagiana, a collection of his witticisms and table talk. The best edition is that by La Monnayo (3 vols., 1698-94). The second part of his Histoire de Sable (1st part, 1658) was edited from the manuscript and published by J. B. Haureau in 1785.

MENAI STRAIT, a narrow channel of Wales, which separates the island of Anglesea from Carnarvonshire. Its direction is nearly S. W. and N. E., its length about 13 m., and its breadth from 200 yards to 2 m. The navigation of this strait in some places is difficult and hazardous; but as the passage saves time and distance, vessels of 100 tons, and sometimes larger, pass through it. The first and last portions of each ebb and flow run in contrary directions in this strait, and the tides are very high, at the equinox sometimes rising to 30 ft. The Menai channel is crossed by two bridges about a mile apart, the Menai suspension bridge and the Britannia bridge. (See BRIDGE, vol. iii., pp. 274, 275.)
for both Greeks and Romans. Of his imitators Terence was the most unscrupulous, his plays being almost entirely in translation or adaptation of his Hellenic master. The *editio princeps* of the fragments of Menander is that of Morellius (Paris, 1553); the best edition is that of Meineke in his *Fragmenta Comicorum Graecorum* (Berlin, 1841).—See Benoît, *Essai historique et littéraire sur la comédie de Menandre* (Paris, 1854), and Guillaume Guizot, *Ménandre, étude historique et littéraire* (1855).

MENARD. I. A. county of Texas, intersected by San Saba river; area, 570 sq. m.; pop. in 1870, 667, of whom 372 were colored. The soil is fertile, and there is fine water power.

Silver mines are known to exist. In 1870 there were 17,876 cattle. Capital, Menardville.

II. A central county of Illinois, bounded N. partly by the Sangamon river, which intersects it; area, 302 sq. m.; pop. in 1870, 11,735. It has a level surface and productive soil. The Jacksonville division of the Chicago and Alton railroad passes through it.

The chief productions in 1870 were 81,949 bushels of wheat, 1,975,880 of Indian corn, 235,091 of oats, 41,456 of potatoes, 37,551 lbs. of wool, 237,375 of butter, and 13,233 tons of hay. There were 6,640 horses, 3,341 milk cows, 10,082 other cattle, 11,113 sheep, and 26,942 swine; 7 manufactories of carriages, 8 of brick, 6 of furniture, 5 of saddlery and harness, 1 of woollen goods, 4 flour mills, and 5 saw mills. Capital, Petersburg.

MENARD, René, a French missionary, born in Paris in 1604, died near Lake Superior in August, 1661. He entered the society of Jesus in 1624, and was the spiritual guide of the Dul-leboast family, prominent in the settlement of Montreal. Menard himself went thither in 1640. He was soon after sent to the Nipissings in Upper Canada; after laboring among them and other Algonquin tribes till the Iroquois completely overthrew the Hurons, he was stationed at Three Rivers. When a mission was begun among the Iroquois, he was sent to Cayuga in 1656, and subsequently to Oneida, and labored with success, though at the risk of his life, and often subjected to personal violence. After the breaking up of the Iroquois missions in 1658 and 1660, he was sent to the Ottawas on Lake Superior to begin a mission in the far west. He suffered greatly from the brutality of the Indians, but reached their country and began a mission at St. Teresa's on Keweenaw bay. In the summer of 1661 he yielded to the appeal of some fugitive Hurons on the Black river, and while toiling to reach them was lost or cut off by Indians.

MANASEEH BEN ISRAEL (properly MANASEEH BEN JOSEPH BEN ISRAEL), a Jewish rabbi, born in Portugal about 1604, died in Middelburg, Zeeland, Nov. 29, 1657. His father fled from the inquisition to Holland, and settled at Amsterdam, where the son was placed under the tuition of Rabbi Isaac Uziel. At the age of 18 he succeeded his master in the office of preacher and expounder of the Talmud. He established a press in his own house, at which he printed three editions of the Bible, and several rabbinical books in the Hebrew and Spanish languages. When he was 35 years of age the family property was confiscated by the inquisition, and he resorted to commerce to retrieve his fortune. During the protectorate he was favorably received by Cromwell, before whom he pleaded for the readmission of his coreligionists into England, writing for that purpose his "Defence of the Jews" (London, 1658). He was the author of *El conciliador del Pentateuco* (Amsterdam, 1632); *Spes Israelica* in Latin and Spanish (London, 1650); and other works in Hebrew, Portuguese, and Spanish. His "Defence of the Jews" was translated into German by Mendelssohn. His life has been written by the Rev. Thomas Pococke (1709).

MENDELSOHN, Moses, a German philosopher, born in Dessau, Sept. 6, 1729, died Jan. 4, 1786. His father was a Jewish transcriber of the tan-teauch and master of a Hebrew day school. He was early sent to the public Talmud school, where he was taught the Mishnah and Gemara, and at the age of seven was usually called up at 3 or 4 o'clock in the morning to proceed to the severe tasks of the school. Even at that age he manifested a spirit of thorough inquiry, and mastered the Hebrew language, so that he could write it with purity and elegance. He subsequently conceived an enthusiastic love for the "Guide of the Perplexed" (Moreh nebukhim) of Maimonides, and his severe study of it led him to the conclusion at an early age to renounce his mental culture and of a chronic nervous disease. About 1745 he followed his friend and teacher Rabbi Fränkel to Berlin, and he lived there several years in extreme poverty. He became intimate with the mathematician Israel Moses, under whom he studied Euclid in a Hebrew translation, and with whom he discussed what he read in Latin and German. Through other friends he obtained elementary instruction in the French and English languages. It had been his custom whenever he purchased a loaf to note it according to his pecuniary prospects into so many meals, never eating according to his appetite, but to his finances. In 1750 he became acquainted with an opulent Jewish manufacturer named Bernhard, and was admitted into his family at first as tutor to his children. In 1754 he became his bookkeeper. He now made the acquaintance of Lessing, and the latter pages of the *Morgen-stunden* record their enduring mutual affection. Their recognized intimacy, and the accession of Nicolai and Abbt to the circle, contributed much to overthrow the Judaeophobism then so prevalent in Germany. In 1755 he published a treatise *Ueber die Empfindungen*, a profound disquisition on problems of aesthetics.
This was followed by other short treatises, which were collected under the title of Philosophische Schriften (Berlin, 1761). He was one of the most active contributors to the Bibliothek der schönen Wissenschaften, and to the Briefe, die neueste Literatur betreffend. In 1783 the royal academy of Berlin awarded him the prize for a memoir on the question: "Are metaphysics susceptible of mathematical demonstration?" though Kant was one of his competitors. The death of his first child in the same year was the occasion of his defending Spalding against Abbt in their controversy on human destiny; and subsequently, imitating Plato's "Phedon," and adding all the arguments for the immortality of the soul suggested by the philosophy of later periods, he produced his Phaidon, oder über die Unsterblichkeit der Seele (Essai An 3), which was not less well-received than almost all European languages, as well as into Hebrew. Mendelssohn's fame was at its height when he received a public challenge from Lavater either to refute Bonnet's arguments in support of Christianity or to renounce Judaism. He answered the challenge with an adroitness and candor that drew from Lavater an apology and retraction of his peremptory address. The agitation caused by this matter induced a long and dangerous illness. Mendelssohn exerted an immense influence by his efforts for the elevation of his coreligionists. His German translation of the Pentateuch and metrical version of the Psalms are admirable for elegance and perspicuity; and their publication, accompanied by Scriptural comments in Hebrew by himself and a circle of friends, marks an epoch in the history of modern Judaism. In defence of the rights of his Jewish brethren he wrote the introduction to his translation of Rabbi Menasseh ben Israel's "Defence of the Jews" (Berlin, 1782). In 1789 appeared his Jerusalem und Judenthum, a vindication both of religious tolerance and of Judaism, and still one of the best books on those topics. He published in 1785 Morgenstunden, consisting of lectures on the existence of God. It contains an affectionate memorial of Lessing, and was the occasion of Jacob's letters to him Ueber die Lehre des Spinoza, in which Lessing was charged with being a Spinozist. Mendelssohn immediately answered in a dissertation addressed to the "Rabbinische Akademie," in which he was seriously injured by the excitement attending this effort, and a slight cold terminated fatally. The most complete edition of his works appeared under the care of his grandson G. B. Mendelssohn (7 vols., Leipsic, 1843-‘5). His life has been written, among others, by Samuels (2d ed., London, 1822) and Kayserling (Berlin, 1862).

MENDELSSOHN-BARTHOLDY, Felix, a German composer, born in Hamburg, Feb. 3, 1809, died in Leipzig, Nov. 4, 1847. He was a grandson of Moses Mendelssohn. His father, Abraham Mendelssohn, had added the name of Bartholdy to his own, out of regard to his wife, a lady of the Bartholdy family. He became a convert to Christianity, and Felix was brought up in the Lutheran faith in Berlin, where his father had founded with his brother Joseph the banking firm of Mendelssohn and co., still continued by the brothers of Felix. Goethe was foremost among the many distinguished persons who became interested in his precocious genius. He was not six years old when he displayed his skill on the piano. Zelter became his instructor in composition, the concert master Hemming on the violin, and Ludwig Berger on the piano. In his ninth year he gave his first public concert in Berlin, and a year afterward he gave one in Paris. From that time he began to write compositions for the piano, violin, viola, and violoncello; and three of his quartets published in the Philadelphia place among classical musical works. In 1825 he made a second journey to Paris with his father, who at length determined to let his son devote himself exclusively to music. He gave successful concerts in Paris in company with Baillot, and after his return to Berlin produced in 1827 his first opera, Die Hochzeit des Gamaches, in which the principal characters of Cervantes's "Don Quixote" are introduced. But the music met with a cold reception, and the opera was immediately withdrawn. He now travelled several years in England, France, and Italy. His overture to Shakespeare's "Midsummer Night's Dream," composed in 1826, was received with unbounded admiration. The rest of the music for that play was written by him afterward as an accompaniment to its performance. He spent some time in Edinburgh, and immortalized the popular music of the Scotch bagpipers by his symphony in A minor, since called the Scottish symphony, which was first performed under his own direction by the London philharmonic society. Many other reminiscences of his tour through the highlands are to be found in his compositions and his orchestral pieces. His overture Die Hebriden reproduces the impressions which the wild shores of the Hebrides had made upon him. He endeavored to establish, in concert with Immermann, musical and dramatic entertainments at Düsseldorf, to consist solely of the most select productions. This enterprise failed, but increased his reputation as a conscientious artist. His residence at Berlin was embittered by the intrigues of his opponents, and in 1835 he accepted the directorship of the famous Leipsic Gewandhaus concerts, which under his care attained to an unprecedented degree of perfection. He was more appreciated in England than in his own country, chiefly on account of his compositions of sacred music. His oratorio "St. Paul," after being produced at Düsseldorf and Leipsic, was performed under his own direction at the Birmingham festival of Sept. 29, 1837, where it was received with great enthusiasm. His fame rests in a great measure upon this oratorio and upon that of "Elijah," which was written for
the Birmingham festival, the first performance taking place there Aug. 20, 1846. Mendelssohn had been engaged for nine years upon this composition, and had resigned the post of inspector of music in Berlin in order to superintend its performance in England; and shortly before his death he was again in London to attend the sacred harmonic society's concert at Exeter Hall. He had resumed his place at Leipzig since 1845; and shortly after his return there from his visit to England in 1847, his health was impaired by grief at the sudden death of his beloved sister Fanny Hensel. A tour to Switzerland for the recovery of his strength brought only temporary relief; a relapse took place soon after his return to Leipzig, and he died in the prime of his manhood from an affection of the brain. Many of his posthumous compositions have been published, including a fragment of an oratorio entitled "Christus," some scenes of "Loreley," a romantic opera, the trumpet overture, the 8th book of his "Songs without Words," and the "Reformation" symphony. Among the most famous of his many published works are his music for Goethe's "Walpurgis Night," the "Antigone" and "Edipus" of Sophocles, and Racine's "Athalie," organ compositions, his symphonies, and a great number of admirable sonatas, concertos, trios, &c. In his "Songs without Words" for the pianoforte, Mendelssohn opened a new vein of beauty, and produced an indispensable work for pianists by throwing aside language and replacing it with musical sentiment, at the same time keeping in view the scope and character of the instrument, and inventing charming traits of accompaniment. Mendelssohn's appreciation of dramatic effect, so remarkably displayed in his music to the "Midsummer Night's Dream," led his friends to expect from him important contributions to the lyrical drama; but his admiration for Bach and Handel and the difficulty that his fastidious taste found in obtaining a satisfactory libretto led him to devote himself to other branches of musical composition. In his oratorios he had the tact to write dramatically, and with freedom from too constant a use of fugue and from antiquated formalism. Mendelssohn was as much beloved for the beauty of his character as for his genius. His life was comparatively free from struggles and cares, and from his earliest childhood he was permitted to indulge his tastes without hindrance. He devoted himself exclusively to his profession, with severe study and a serene and dispassionate mind.—His life has been written by W. A. Lampadius (Leipsie, 1848; English translation, New York, 1865). See also "Recollections of Mendelssohn-Bartholdy," by Edward Devrient (English translation, London, 1869); Goethe and Mendelssohn, by Karl Mendelssohn (English translation, London, 1872); and Mendelssohn-Bartholdy, Briefe und Erinnerungen, by Ferdinand Hiller (Cologne, 1874; English translation, London, 1874).
next visited Pegu, Siam, Java, and some of the neighboring countries, and in 1547 he made a second voyage to Japan. Soon after his arrival there a civil war broke out, in which Pinto took part for a while; and having returned to Malacca, he met St. Francis Xavier, "the apostle of the Indies," with whom in the course of a few months he made a third visit to Japan, arriving there in August, 1548. By these voyages Pinto acquired great wealth, and in 1553 he was at Goa, preparing to return to Portugal, when the arrival there of the body of Xavier, and his conferences with the Jesuits, so excited his religious enthusiasm, that he devoted his whole fortune, except 2,000 crowns which he sent to his poor relations in Portugal, to the foundation of a seminary for propagandists in Japan. He was then appointed ambassador from the Portuguese viceroy of India to the prince of Bungo in Japan. Before setting out he took the vows as a Jesuit; but on his arrival in Japan his zeal evaporated, and he was released from his vows. He returned to Lisbon, where he arrived Sept. 22, 1558, bearing to the queen regent a letter from the viceroy of Goa, recommending him warmly to the favor of the government. He spent a few years in attendance on the court, which brought him nothing but promises, and which he says were more tedious and harassing than his 21 years of service in the East, where he had been 13 times taken by the enemy, and 17 times sold as a slave. The first extant account of his travels and adventures is given in a collection of Jesuits' letters published in Italian at Venice in 1565. He wrote a full narrative of his life, which was published by Francisco de Andrade under the title of Peregrinação de Fernão Mendes Pinto (4to, Lisbon, 1614). A Spanish translation by Francisco de Herrera, in which great liberties were taken with the original, appeared in 1629; a French translation was made by Bernard Fignon, of which three editions have been printed (Paris, 1628, 1645, and 1830), and an English translation by H. Cogan, of which there have been two editions (London, 1663 and 1692). Pinto's reputation has suffered greatly by an oft quoted line in Congreve's "Love for Love:" "Ferdinand Mendez Pinto was but a type of thee, thou liar of the first magnitude!" But it is now alleged that his general veracity cannot be disputed.

MENDICANTS, or Begging Friars. See Religious Orders.

MENDIZABAL, Juan Alvarez y, a Spanish financier, born in Cadiz about 1790, died in Madrid, Nov. 3, 1853. He was the son of a trader of Jewish descent named Mendez, and in 1808 obtained employment in the victualling department of the French army in Spain. In 1819 he took part in the secret movements which culminated in the revolution of the following year, and subsequently aided the constitutional government in the negotiation of loans. Fleeing to England on the suppression of the revolution, he was imprisoned at the instance of English capitalists whom he had induced to take parts of a loan. After the recovery of his liberty he founded in London a commercial establishment with the aid of funds deposited with him by a friend. He formed the acquaintance of an agent of Dom Pedro of Portugal, and in 1827 negotiated a loan for him. This and other operations gave him an extensive reputation both in England and Spain, which in June, 1835, led to his appointment as minister of finance in the cabinet of Torreno; but he continued to reside in London, where in August he negotiated a loan for the Spanish government. On his return to Madrid he became president of the council. The cortes placed 100,000 men at his disposal, and gave him full authority to bring the divisions, then in a close state, to a conclusion. But he injured the credit of the government by jobbing transactions, increased the public debt, dissolved the cortes (Jan. 27, 1836), and replaced the French ambassador, who opposed his influence, and was compelled to resign (May 15). His reappointment as minister of finance (Sept. 11) caused great indignation, and on Aug. 10, 1837, he withdrew from office. In 1841, under Espartero, he was once more minister of finance, but shared his fall in July, 1843. He afterward lived in great splendor for several years in Paris.

MENDOCINO, a N. W. county of California, bordering on the Pacific, and drained by the head waters of Eel and Russian rivers, and by numerous other streams; area, 3,816 sq. m.; pop. in 1870, 7,545, of whom 129 were Chinese. The interior is mountainous, but generally adapted to agriculture or grazing. Along the coast the mountainsides are covered with forests of redwood. The chief productions in 1870 were 95,939 bushels of wheat, 128,971 of oats, 64,870 of barley, 83,476 of potatoes, 178,498 lbs. of wool, 62,692 of butter, 59,400 of hops, and 10,116 tons of hay. There were 4,405 horses, 2,431 milch cows, 7,906 other cattle, 49,839 sheep, and 18,108 swine; 2 flour mills, 15 saw mills, and 6 manufactories of saddlery and harness. Capital, Ukiah.

MENDOZA. I. A S. W. province of the Argentine Republic, bounded N. by San Juan, E. by San Luis, S. by the unsettled districts W. of Buenos Ayres, and W. by Chili, from which it is separated by 476 sq. m.; pop. in 1869, including inhabitants of foreign birth, 65,413. The entire western portion of the province is mountainous, being covered by the main chain and detached spur of the Andes; while to the east is a ridge extending southward from the province of San Juan and forming the dividing line with San Luis, being a continuation of the Pamiatina mountains of La Rioja. In the vicinity of the capital rises the Paramillos chain, whose maximum elevation is about 10,000 ft., and near these lies the lofty valley of Uspallata, with a mean elevation of 6,000 ft. Among the peaks skirting this part of the republic
are some of the highest in the Andes, including Aconcagua, the culminating point of America, and at the extreme south are the Nevada and Payen systems, the former attaining to a height of 15,000 ft. Nearly all the mountains here referred to are volcanoes, some of which are in continual eruption. The principal rivers are the Mendoza and the Tunuyan, the first descending from Aconcagua, and each forming several lagoons from which extend natural canals very useful for irrigation.

Agates, amethysts, carnelians, and sapphires are found. Several gold mines were formerly worked; in the Usquilata valley are mines of argentiferous lead; copper, iron, lime, chalk, pumice stone, coal, pitch, petroleum, and beautiful marbles are very abundant. Mineral springs are common in the west; and there are thermal springs celebrated for their medicinal properties, and for a copious yield of boracic acid. The climate is salubrious, and the soil is generally fertile, save in the south, where it is naturally sterile, but improved by irrigation and manuring. The chief products of the forests are white and black poplar; cereals of all kinds are abundant, as are also the grape and a great variety of other fruits; and cotton, tobacco, and hemp grow well. Cotton and woolen stuffs are manufactured, and several sorts of fruit are preserved; but there is great lack of means of transport to the sea. Most of the products are sent across the Andes by the paso del Portillo into Chili. There are numerous schools; but of 17,216 children between 6 and 14 years in 1869, only 2,132 attended school; and 55,395 persons out of the whole population could neither read nor write. Mendoza is divided into twelve departments. It formed a part of the captaincy general of Chili until 1776, when it was annexed to the viceroyalty of La Plata. II. A city, capital of the province, 610 m. W. N. W. of Buenos Ayres; pop. in 1869, 8,124. It is surrounded by several canals, one of which traverses the town, and the banks of all of which are fringed with poplars. Every available spot of land in the vicinity is highly cultivated. The chief occupations are agriculture, wine making, and fruit preserving. It was almost totally destroyed by an earthquake in 1861, but is in rapid course of reconstruction. In 1776 Mendoza was made the seat of government of the viceroyalty of La Plata.

MENDOZA, a family of Spain, several of whose members have been distinguished. 1. Ildefonso Lopez de, marquis de Santillana, born at Carrion de los Condes in 1398, died in Guadalajara, March 26, 1458. He inherited vast estates from his father, the grand admiral of Castile. He was successful against the Aragonese in the battle of Araviana and the defence of Alcalá, and as commander of the army sent against the Moors, whom he repeatedly overthrew; for all which exploits he obtained the titles of count and marquis. He afterward went to court, and took part in the interning struggles of the kingdom. He cultivated letters, and was the friend and protector of the learned of his time. The peculiarly Italian form of the sonnet was introduced by him into Spain. His chief production is the Comedias de Fonza, founded on the story of a naval combat near the island of Fonza in 1455; his most popular is the Refranes, "Proverbs," sometimes called the Centiloquio, as it comprises 100 rhymed sentences. His other productions embrace sonnets, a Canto funebre on the death of Enrique de Villena, critical and historical dissertations, and poems. II. Pedro Gonzales de, son of the preceding, born in Castile in May, 1428, died in Guadalajara, Jan. 11, 1495. Before 1473 he was archbishop of Seville, and in that year he became cardinal of Spain. He distinguished himself in the battle of Toro, March 1, 1476, and shortly afterward accompanied Queen Isabella to put down the rebellion at Segovia. In 1479 he showed much favor to the persecuted Jews. He was translated to the archbishopric of Toledo in 1482, and appointed grand guardian of the Alhambra in 1492. From his great influence at the court of Ferdinand and Isabella, he was usually called rey tertius, "the third king." III. Juan Hurtado de, son of the count Tendilla, and grandnephew of the marquis de Santillana, born in Granada about 1503, died in Madrid in April, 1575. He was educated at the university of Salamanca, and learned Arabic at Granada, where he wrote his Lazarillo de Tormes (Antwerp and Burgos, 1554). This is a satirical romance, and became the foundation for the whole class of Spanish fictions in the género picaresco, which the Gil Blas of Le Sage subsequently made famous throughout Europe. The Lazarillo was attributed by a conscientious authority to Jose de Soto Reta. (See Nicolas Antonio's Bibliotheca Nova, vol. i., p. 291.) A Paris edition was published in 1602, and a French translation (including a second part from another pen, very inferior to Mendoza's) in the same year. The first part was prohibited by the inquisition. After leaving the university he served in the Spanish armies in Italy, where he profited by the teaching of the professors at Bologna, Padua, and Rome. Charles V. sent him as ambassador to the republic of Venice in 1538, and there he exerted himself for the collection of Greek manuscripts. He was charged with the imperial interests in the council of Trent, whence he was withdrawn in 1547, to command the Spanish garrison at Siena. Having been expelled from Siena by the inhabitants, he set out immediately as special plenipotentiary to Rome. For six years he was regarded as the head of the imperial party throughout Italy. He returned to Spain when the emperor changed his policy before abduction. Philip II. banished him from court in 1567, and he retired to Granada. Toward the end of 1574 he was permitted to return to Madrid; but he soon died. His poems display the old Castilian national tone of sentiment and reflection, modified by his
familiarity with the classical and Italian poets. His epistle to Boscain and hymn to Espinosa attest at once great genius and vast classical erudition. There is but one edition of his poems (4to, Madrid, 1610). His principal historical work is the Guerra contra los Moriscos, a record of the Moorish insurrection. The author is so impartial with respect to the enemies of his faith and people that the book could not be published till long after his death (Valencia, 1776). His life by Antonio is contained in the Bibliotheca Nova. IV. Antonio de, brother of the preceding, born in Granada about 1496, died in Lima, July 21, 1502. On April 17, 1505, he was appointed viceroy of New Spain, where he arrived in October, invested with full power to act in opposition to previous royal orders. His administration was distinguished by many wise reforms, especially in matters concerning the Indians, whose sufferings were materially alleviated by his efforts. In 1536 he introduced into the city of Mexico the printing press, the first brought to the new world, and the first coined, in the same year, was done by his orders; he also founded the first college there (1537). In 1551 he was transferred to the viceroyalty of Peru. He was the first of a series of 64 viceroys in New Spain, and his administration was the longest and most illustrious of them all.

MENELAUS, one of the Homeric heroes, king of Lacedemon, son of Atreus and younger brother of Agamemnon, and husband of Helen. After his wife had eloped with Paris, he and Ulysses proceeded to Troy to demand her restitution. In the war which followed the refusal he repeatedly distinguished himself, slaying many Trojans in single combat. He also engaged Paris, and would have killed him had not Venus interfered and enabled her favorite to escape. Menelaus was one of the warriors concealed in the famous wooden horse. On recovering Helen he embarked for home; but when he arrived off Cape Malea Jupiter sent a storm which scattered his fleet, and drove his ship as far as Egypt. With the exception of Ulysses, he was the last of the Hellenic heroes that reached Greece. He is said to have been the father of several children by Helen.

MENENDEZ DE AVILES, Pedro, a Spanish admiral, colonizer of Florida, born at Aviles in 1519, died in Santander, Sept. 17, 1574. He cruised for many years against French corsairs, on his own account and under commission from Charles V., with great success. Philip II. appointed him captain general of the India fleets, and his councillor. He conveyed Philip from Corunna to England to marry Queen Mary. Returning to Spain, he engaged some pirates on the way, took command of the India fleet, and, running across, returned with a valuable fleet long before he could have been expected. He next swept away the piratical vessels hovering on the coast of Spain; then with only four vessels he carried to the Low Countries money and reënforcements that enabled Philip to win the battle of St. Quentin. He was constantly employed during the war, and toward the close he crossed France in disguise, to fit out a fleet to convey Philip back to Spain. He landed the king and court with his usual celerity. He was next made general of the India fleet, and did not return to Spain till July, 1566. In 1568 he was appointed adelantado of Florida, with orders to plant a colony. While preparations were on foot, tidings came that French Huguenots, under the auspices of Coigny, had settled in Florida. The desire of breaking up this colony led to increasing the force of Menendez. His fleet of 34 vessels carried 2,646 persons, including cultivators, mechanics, priests, and soldiers. He sailed from Cadiz June 29, 1568, and vessels for his colony sailed about the same time from other ports of Spain. On reaching Porto Rico in August, with a small part of his force, Menendez heard that Ribault had reinforced the French, and that a Spanish vessel had been captured. He ran into the St. John's river, and announced to the French his name and his purpose of exterminating them. He then returned to St. Augustine, which he discovered and named. Ribault followed and attempted to invest him; but he was driven off by a storm, and Menendez resolved to proceed overland and surprise the French fort, and carried out his plans amid great difficulties. Fort Caroline was captured, and nearly all the colonists of both sexes were put to the sword; some escaped with Landonnire to the French ships, and about 70 were spared. Menendez garrisoned the fort, called it San Mateo, and returned to St. Augustine. Meanwhile Ribault had been wrecked on the coast, and after much suffering from hunger he and his followers surrendered on promise of mercy from Menendez. With atrocious perfidy and cruelty they were nearly all put to death. (See RIBAULT.) Menendez then pushed on his works at St. Augustine, and established Fort Santa Lucia at Cape Carnavela, and Santa Elena at Port Royal harbor, S. C. The next year Sanchez de Arciniega brought out 1,500 more settlers with supplies. Menendez sent up to explore the coast as far as St. Mary's, now Chesapeake bay. He then returned to Spain to report what he had effected. During his absence Dominique de Gourgues, a French adventurer, captured San Mateo and avenged the massacre of the French. (See Gougues.) In 1570 Menendez sent a vessel with a colony of Jesuits to begin a mission on the Rappahannock. An Indian chief, who had been in Mexico and Spain and become a Christian, was their guide, but he turned traitor, and the whole party were massacred. Menendez on his return from Spain in 1572, hearing of the destruction of the colony, at once sailed up the Potomac and avenged the massacre. He then explored the whole coast, and was devo- ting himself to the increase of his colony when
the king appointed him to command a fleet destined against the Low Countries. While pushing forward the preparations he died.

**MENES.** See Egypt, vol. vi., p. 459.

**MENGS, Anton Rafael**, a German painter, born at Aussig, Bohemia, March 12, 1728, died in Rome, June 29, 1779. His father, a miniature painter, took him when a child to Dresden, and compelled him to pursue his art studies without relaxation. Young Mengs threw so well under this severe treatment, that in his eighth year he designed a subject from the Aeneid, and at 14 was a skilful painter. In 1741 his father took him to Rome, and compelled him to devote nearly his whole time to the study of the works of Raphael and the old masters in the Vatican, of which he made several copies in miniature for Augustus III. of Poland and Saxony. Returning to Dresden at the end of three years, he was appointed court painter, with permission to return to Rome, where he established his reputation by a holy figure, the picture of the Virgin in which was painted from a beautiful peasant girl, whom he subsequently married. In 1749 he was again in Dresden, but in 1751 obtained the permission of the elector to return to Rome. Here he undertook the direction of the new academy of art. Among the works which he executed in the next few years were a copy of Raphael's "School of Athens" for Lord Percy, afterward duke of Northumberland, the frescoes in the church of San Eusebio (1757), and those of "Apollo and the Muses on Parnassus" in the villa Albani, which were engraved by Raphael Mengs. The king of Naples, on succeeding to the throne of Spain as Charles III. invited him in 1761 to Madrid, where he executed a number of works in the royal palace, including his "Aurora." In 1770 he again went to Italy, where he executed a great allegorical screen painting. After three years he returned to Madrid, and produced several works, including his masterpiece, the "Apotheosis of Trajan." On a visit to Monaco he painted his picture of the "Nativity." In 1776 he returned to Rome for the last time. His merits have been much exaggerated by his friends, and quite as much underrated by others. As a theorist and writer on art he is still a standard authority, and his remarks on the antique and criticisms of the works of the old masters were highly esteemed by the artists of his own age as well as by Winckelmann, Lanzi, and other eminent critics and historians of art. His writings were published under the title Opere di Antonio Raffaele Mengs (Parma, 1780), and have been translated into Spanish, German, English, and French.

**MENIFFE,** an E. county of Kentucky, bounded N. E. by Licking river and S. by Red river, a tributary of the Kentucky; area, about 450 sq. m.; pop. in 1870, 1,986, of whom 16 were colored. The surface is hilly and broken; the soil is generally productive. The chief pro-

**MENHADEN.** See Brain, Diseases of the, vol. iii., p. 260.

**MENIPPE, a cynic philosopher, originally a slave, a native of Gadara in Syria, lived toward the close of the 4th. or, according to others, about the middle of the 1st century B. C. He amassed great wealth by usury, but was cheated out of it, and committed suicide in despair. He was the author of 13 treatises, all of which are lost. His works contained nothing serious, but abounded in jests and sarcasms. Lucian, in his "Dialogues of the Dead," makes Diogenes describe him as an old bald-headed man in a tattered cloak, incessantly ridiculing the pedantry of his brother philosophers.

**MENHADEN,** a North American fish of the herring family, and genus *alosa* (Cuv.), which differs from the herrings (*clupea*) in having a deep notch in the centre of the upper jaw. This fish (A. menhaden, Storer), called also

---

Menhaden (*Allosa menhaden*)

hardhead and mossbunker by fishermen, varies in length from 8 to 14 in.; the color above is greenish brown, darkest on the top of the head and at the snout; upper part of sides roseate with indistinct bluish mottlings, disappearing after death; abdomen silvery, gill covers cupreous, a black spot upon the shoulders, and the whole surface iridescent. The body is elongated and compressed, the gill covers very large, eyes moderate, gape large, and lower jaw the shorter. This species comes into Massachusetts bay in May, and departs in November; great quantities are taken in nets around the outer islands of Boston harbor during the night; sometimes 100 barrels are taken at one haul, and such as are not ground up for bait are sold for food at about half a cent each; being rather oily, they are not very palatable, but make excellent murre. A single menhaden of common size is considered equal in richness to a shovelful of barnyard murre; in some parts of Cape Cod they are sold at $1 a thousand, and 2,500 are considered sufficient for an acre of land; the odor arising from their decomposing bodies is almost unendurable. They are found from the British provinces to the coast of New Jersey, swimming in countless numbers near the surface, and attended by sharks, bluefish, gulls, and other predaceous species. They are never
MENNONITES

found in fresh water.—Menhaden oil is of value, being used principally in leather dressing, but also to some extent in rope making and for painting. The scrap or refuse, after extracting the oil from the boiled fish, is used in the manufacture of fertilizers. The business of catching menhaden for oil and guano has within 15 years assumed extensive proportions. It is carried on from Maine to New Jersey, and is especially prominent in the E. portion of Long Island. They are caught chiefly in purse nets as far out as 30 m. from land, but also in shore seines and other nets. Those taken on the Maine coast yield more oil than those caught further south. In 1873 there were 62 factories in operation on the coast of New York and New England, employing 388 sailing vessels and 20 steamers, with 2,306 men on shore and at sea; capital invested, $2,388,000; total catch, 1,193,100 barrels (250 fish to a barrel), yielding 2,214,800 gallons of oil and 36,299 tons of guano; value of products, about $1,600,000.

MENNONITES, a denomination of Protestants who reject infant baptism and baptize adult persons only on a profession of faith, and practise non-resistance and abstemious from oaths. They thus combine some of the leading principles of the Baptists with some of the distinctive views of the Friends, though historically they preceded both. Originally they were called by their opponents Anabaptists, while they called themselves in Switzerland and south Germany Täufer, i.e., baptizers; in the Netherlands Doopgezinde, i.e., persons holding special views as to baptism. They were called Mennonites because they were reorganized and more fully indoctrinated by Menno Symons. The chief points in their history are the following. In January, 1525, at Zürich, two young scholars, Conrad Grebel and Felix Manz, and a former monk, George Blaurock, organized the first church which professed all the leading principles of the body. They rapidly spread in Switzerland, being most numerous at St. Gall. Persecution soon drove many of them to southern Germany, where Augsburg and Strasbourg became their strongholds. Here also persecution broke out, and more than 8,000 of them suffered martyrdom in Swabia, Bavaria, Austria, and Tyrol. They found refuge in Moravia, where they greatly increased, until the thirty years' war drove them away. About 1545 a confession of faith was published by them in Moravia (republished, Berlin, 1869), which distinctly enjoins pouring as the mode of baptism. When in 1527 and 1528 various leaders of the Anabaptists had perished at the stake, enthusiasts rose in their places. The chief among these were Melchior Hoffman, a Swabian, through whom the principles of the Anabaptists, mixed with his chiliastic views, were first disseminated in the Netherlands. His fanatical follower, John Matthias of Harlem, in 1533 inaugurated the atrocities of Münster in Westphalia, which, though committed by men who had deviated from the original principles of the sect, were charged to the whole body. The history of the Dutch Mennonites, as after the accession of Menno Symons the Anabaptists were called, is written in blood. About 6,000 of them suffered martyrdom under the rule of Philip II. of Spain. When the Netherlands rose for their independence, William of Orange favored them, but other leaders of the reformed party opposed them, and it was not till 1651 that toleration was secured to them by a general law. Besides oppression, internal dissensions greatly checked their growth. In 1597 they were divided into two parties, the more rigid being called the Frisians, the more moderate the Flemings, to which a third party, the Waterlanders, was soon added. The points of difference between these parties related only to church order and discipline. About the middle of the 17th century doctrinal dissensions brought about new divisions. All Mennonites agreed in doctrine with the Remonstrants or Arminians of Holland; but when some of them, with a large part of the Remonstrants, adopted Socinian views, the other Mennonite churches opposed them. It was not till 1801 that all Dutch Mennonites were reunited in one body and founded a theological seminary at Amsterdam. At present they enjoy full religious liberty, and are highly respected; many of them are among the richest men in the country; but their number has decreased from 160,000 in 1700 to fewer than 20,000 in 1873. In Switzerland the Mennonites, up to the middle of the present century, were oppressed in many ways, one of which was, that their infants were forcibly taken from them to be christened. In consequence of this, large numbers emigrated to Alsace and the Palatinate. At present they number in Switzerland and southern Germany about 8,000 communicants, and in East Friesland, the province of West Prussia, and other parts of northern Germany, about the same number. They are more numerous in southern Russia, whither they began to emigrate from West Prussia in 1783, settling first on the banks of the Dnieper, and later near the sea of Azov. Here they acquired considerable wealth, and in 1870 formed a population of about 40,000. By special decrees of the emperors they were exempted from military duty. In 1871, however, this privilege was abolished, and no alternative was left them except conscription or emigration, the privilege of emigration being confined to, the period from 1871 to 1880. This measure caused thousands to emigrate to the United States. The first colonies, arriving in 1873, settled in Minnesota and Kansas. The emperor subsequently modified the decree relative to conscription with a view of arresting the movement. The emigration of Mennonites to the United States began with the settlement of New York, some of them having been among the first Dutch settlers. The first church was organized in 1683 at Germantown near Phila-
MENNONITES

Hunzinger, but founded Mennonites, minerals Philadelphia, Herr, man body, to ascertain to Pennsylvania and Maryland to the western states and Upper Canada. As few of them keep lists of membership or minutes of their annual conferences, it is impossible to ascertain their exact number. According to the most recent estimates, the number of their communicants in America is about 60,000, with 500 meeting houses, those in Canada constituting one eighth of the whole. They are most numerous in Pennsylvania, Ohio, Indiana, and Canada. Their principal divisions are:

1. The Old Mennonites, by far the largest body, having a publishing office at Elkhart, Ind.
2. The Reformed Mennonites (in German Herrn-Leute), founded in 1811 by John Herr, who returned to the rigor of the ancient Frisian Mennonites, prohibiting all religious intercourse with other Christians, even at funerals and family prayers. They are very strict in the reception of members and in the separation from the excommunicated. 3. The New Mennonites, organized in 1697 by J. H. Oberholtzer, have introduced various reforms, and founded a theological seminary at Wadsworth, Ohio. Their publishing office is at Milford Square, Pa.

The Evangelical Mennonites separated from the preceding party in 1856, because they held it to be a duty of all Christians to hold stated meetings for prayer.

5. The Amish Mennonites, usually called Omish, next to the Old Mennonites, are the most numerous in America. They first rose in 1696 in Alsace. Their founder, Jacob Amman, under whom they were named, enjoined on his adherents strict separation from the excommunicated, feet washing, and greater plainness in dress. They discarded the use of butons on their clothing, and hence were called Hafter or Hooker Mennonites, while the others were known as Knopfler or Buttonites.

In their general doctrines the Mennonites agree with the great body of evangelical Christians. In church government they are in Europe Independents, while in America they somewhat resemble Presbyterians, inasmuch as the resolutions of their annual conferences are binding on the churches. They have bishops, preachers, and deacons; but the only difference between the bishop and the preacher is that the former is ordained, the latter only licensed to preach. Baptism is administered to almost all children of Mennonites when they arrive at a certain age, in Germany in their 14th year, in Holland and America about their 18th. The mode, except among the Evangelical and some of the New Mennonites, is always pouring. The Lord's supper is celebrated twice a year, preceded in America in a large majority of churches by feet washing. All Mennonites consider honesty, industry, and plainness of dress and manners to be prominent Christian duties. They do not assume public offices, which would make it necessary for them to take an oath or to inflict punishments. They never go to law. On this continent, as in most parts of Europe, they are nearly all farmers.—Almost the entire Mennonite literature is in Dutch and German. The principal works are: T. J. van Braght, Het bloedige tooneel der Doopgezinde en veerloze Chris- tenen (Dort, 1660; Amsterdam, 1685); Hermann Schyn, Historia Christianorum, qui in Belgoto Fideerato Mennonita appellantur (Amsterdam, 1725 and 1729); Blaupen ten Cate, Geschiedenis der Doopgezinden in Friesland, Holland, Zeeland, &c. (Amsterdam, 1837–50); J. A. Starck, Geschichte der Taufe und der Taufgezogenen (Leipsic, 1789); Hunzinger, Das religiöse Kirchen- und Schulwesen der Mennoniten (Spire, 1881); and Cornelius, Geschichte des Münsterischen Aufbruchs (Leipsic, 1855).

MENNO SYMONS (commonly written Menno Simons, and defined as "Menno, son of Si- mon;" but Symons was his surname), a religious reformer, born at Witzmarsh in West Friesland about 1496, died at Westenfelde, Holstein, Jan. 13, 1561. In 1524 he became a vicar at Pingium, where he studied the Bible and preached repentance. In 1531, in the neighboring city of Leeuwarden, Sicke Snyder, an Anabaptist, was beheaded. This led Menno to examine the question of infant baptism, which he thereafter considered unscriptural. Yet he accepted a call as curate of Witzmarsh, and while he resided there a band of Anabaptists seized and fortified a cloister in the vicinity, but were captured and put to death (February, 1535). Menno's brother was among the slain, and he reproached himself for not having joined these brethren, in order to teach them better. Re- nouncing his Roman Catholic chasms, and in the priesthood, and accepting a call to be the pastor of a few Anabaptists who never had been connected with the fanatical party, Menno began the life of an itinerant preacher, and with others organized numerous churches, principally in West Friesland. In 1543 persecution became so severe that he had to leave his native province. He first went to Cologne, where he flourished church was gathered. Driven from there in 1546, he travelled in Holstein, Mecklenburg, and Livonia, preaching and organizing churches. The last years of his life were embittered by dissensions among his adherents on the nature of ecclesiastical excommunication. The stricter party, led by Bouwens, insisted on total separation from an excommunicated person, even on the part of the wife. The milder party objected to this. Menno, to avoid excommunication, sided with the stricter party, a step which he afterward
MENOBANCHUS

found in the great lakes of North America and in Lake Champlain, and in the streams opening into them. In *M. lateralis* (Say) the color is dusky brown above, with a dark band from the nostrils through the eye and along the sides to the tail, and dirty flesh-colored

below; the form is more slender than in the other species; it is found only in the western waters running into the Mississippi, especially if not entirely on its eastern side, from Pennsylvania to Tennessee; it is often called mud puppy. In many specimens kept alive by the writer, some of them for three or four years, obtained from Portage lake, the gills, three on each side, were provided with an immense number of very delicate fringes, deep red when the animal was actively breathing, which were kept waving to and fro in a most graceful manner during respiration; the four limbs, about an inch long, were set almost at a right angle, and the gait was consequently very awkward; the movements executed by the tail are rapid and graceful; the vent is longitudinal; the general aspect of the head is snaky and forbidding, and the Indians erroneously consider them venomous. The specimens above mentioned were very tenacious of life, having been imprisoned under ice half an inch thick every night for three months without apparent injury, and ate nothing for six months except what they obtained from the water. They often came to the surface to swallow air, which is emitted at the gill opening in bubbles accompanied by a faint squeak. Generally sluggish in their motions, and avoiding the sunlight, they seize living worms eagerly, sucking them down if small at a single gulp, or, if large, by repeated efforts; the sight is not very good, and they rarely snap at their prey unless it touches their mouth. They are sometimes taken on hooks by persons angling for mud fish; they are most active at night, moving rapidly at this time, and often throwing themselves nearly out of water; they feed on insects, worms, small crustaceans, and other living prey. The gills when inactive shrink, and become of a slaty gray color; they are cleansed from impurities by means of the fore feet. When the branchial fringes are lost by accident, the animals do not appear to suffer. They have rudimentary lungs or pulmonary sacs, which assist in respiration by means of the swallowed air; but these are not sufficient of themselves to support life, as the animals die out of water in about four hours; with the cutaneous respiration, active in all amphibians, the air sacs are able to purify the blood. These animals, having both lungs and gills, though the former are insufficient to prolong life except for an hour or two, probably come as near as any to the fabulous amphibians able to live in water or air. There is no evidence that this animal, like the axolotl, is developed into any terrestrial salamander. (See **Axolotl**.)

**MENOMINEE**, a S. W. county of the upper peninsula of Michigan, bordering on Green bay, separated from Wisconsin by the Menominee river, and watered by several streams; area, about 1,300 sq. m.; pop. in 1870, 1,791. The surface is broken and hilly, and the soil moderately fertile. There are extensive forests. It is traversed by the Peninsular divi-
sion of the Chicago and Northwestern rail-
road. There were 4 saw mills in operation in
1870, producing lumber to the value of $599,-
000. Capital, Menominee.

MENOMONEES, or Menominies, a tribe of Amer-
ican Indians, belonging to the Algonquin fam-
ily, and from their first discovery to the pres-
cent century residing on the Menominee river,
which empties into Green bay, Wis. Their
traditions point to an emigration from the east,
but as early as 1640 they were known to the
French as residing near Green bay, their
name being that of the wild rice on which they
in great part subsisted. Missions were es-
established among them as early as 1670 by the
Jesuits Allouez and André. They were lighter
in complexion than the neighboring tribes,
and remarkably well formed. They continued
friendly to the French till the troubles caused
by La Salle's monopoly, when they are said to
have instigated the murder of some men em-
ployed at the Jesuit mission; but they made
reparation, and when the Foxes made war on the
French, the Menomonees marched to the
relief of Detroit in 1712, and subsequently
drove the Foxes from the bay. In the opera-
tions against the English they were frequently
in the field from 1712 to 1763, some of their
braves figuring in Braddock's defeat and the
battles of Fort William Henry and the Plains
of Abraham. When the American revolution
began, they, under their chief Chakauchokama,
or Old King, adhered to the English side, and
a part of the warriors went to Montreal; but
Clarke's success in Illinois checked all opera-
tions on their part in the west till 1780, when
they served in the expedition against the Span-
iards at St. Louis. After the close of the war
they remained friendly till the second war with
Great Britain, when they were again won over
by English officers, and under Thomas Car-
ron helped to capture Mackinaw in July, 1812,
fought under their chief Soulligny with Tecum-
seh at Fort Meigs in 1813, and under Carron
and Grisy Bear were repulsed by Croghan at Sandusky. They were also at the battle of
Mackinaw in 1814, and probably in the capture
of Prairie du Chien. On March 30, 1817, To-
wanapoo and other chiefs made a treaty with
Clarke, Edwards, and Chouteau, ratifying land
grants of the French, English, and Spanish gov-
ernments, and giving up prisoners. The treaty
of 1825 recognized their territory as bounded
N. by the Chippewa country, E. by Green bay
and Lake Michigan, south by the Milwaukee
river, and W. by the Black. The treaty of 1827
settled the line between them and the Chip-
pewas. That of Feb. 5, 1831, began the cessa-
tion of their lands and the payment of money.
That of Sept. 3, 1836, ceded a large tract for
$620,110. In the mean time they served the
United States in the Sac and Fox war. In
1862 and 1868 the official reports give half or
two thirds of the tribe as Catholic, the rest be-
ing pagan. Schools have been maintained with
great regularity, but inconceivable effect on
the tribe, very few acquiring English. After
the cession of their lands their reservation was
between the Wisconsin, Wolf, and Fox, and the
Chippewa country. By a treaty in 1848 they
were to remove west of the Mississippi; but the
nation repudiated the treaty. In Novem-
ber, 1852, they were placed on the Upper Wolf
and Oconto rivers, Wisconsin, 50 m. from Green
Bay, and the reservation was secured to them
by treaty in 1854. It consists of 390,400 acres
of very poor land. Oshkosh, grandson of Old
King, was at this time the head chief, and re-
mained so till his death in 1858. They refused
to join the Sioux in their outbreak in 1861,
and several of the warriors served as volun-
teers in the United States army during the civil
war. They have declined rapidly in numbers.
In 1823 they were estimated at 3,900, and in
1872 were reported at 1,480. Disease, and es-
pecially intoxication, which seems ineradicable,
are steadily destroying the tribe. Their lan-
guage is a very peculiar Algonquin dialect, with
strange guttural sounds and accents, and dif-
fers from the other dialects in the collection of
the verbs and other parts of speech.

MENOPOMA, a North American tailed batrach-
ian reptile, one of the series of animals which
seem to connect the perennibranchiate amphibi-
as with the salamanders. The genus
menopoma was established by Harlan in 1825,
though Leachhardt had formed the genus cryp-
tobranchus in 1821. The generic characters are:
large and flat head; upper jaw with two
concentric series of minute teeth, the inner
the less extensive, lower jaw with a single se-
ries; a single branchial orifice on each side;
branchial rudimentary and evanescant; ex-
tremities four, the anterior with four fingers,
the posterior with five, short and palmed;
skin loose and folded on the sides of the body.
The common menopoma (M. Alleghaniene, Harlan) attains a length of about 15 in., of

---

Menopoma Alleghaniene.—1. Head. 2. Mouth.
MENOPOMA

orifice; tail large, much compressed laterally, with a rayless cutaneous fin along the upper border. The color is said by De Kay to be pale slate, mottled with dusky. It lives in fresh water, and is carnivorous and voracious, feeding on fish, worms, and mollusks; it is found in the Allegheny river and its tributaries, and many of the branches of the Ohio and Mississippi; its most common name is “hellbender.” Dr. Holbrook describes another species (M. fuscum), from western South Carolina, brownish above and yellowish white below; both species have the limbs fringed posteriorly.—Van der Hoeven places the gigantic salamander of Japan in the genus crypsotobranchus, under the name of C. japonicus. This animal, the largest of the known naked amphibias, growing to a length of more than 3 ft. and to a weight of nearly 20 lbs., was discovered by Siebold, who had several specimens alive, and kept one for many years in Europe. The form is robust; the tail occupies about one third of the length, and constitutes the principal organ of locomotion, assisted by a loose fold of skin extending from the head along the sides to the origin of the tail; the lips are not very distinct, and the tongue is small; the occiput is separated from the neck by two wide protuberances formed by the muscles of the jaws; the skin above is covered with numerous rough prominences, which give it a very forbidding appearance; the color is dark brown, with wide blackish spots. Van der Hoeven maintains that this is not distinguished from menopoma by any generic character; it resembles the latter in form, habits, bones of the skull, number of vertebrae (20 in the trunk and 24 in the tail), sternum, pelvis, ribs, and extremities; the bones present cavities opening externally; there is no gill aperture, and the branchiæ disappear early. It is slow in its movements, remaining quiet at the bottom of the water, rising to the surface every five or ten minutes to breathe air both by the nostrils and the mouth, but able to remain half an hour under water without renewing the contents of the lungs; generally inoffensive, it will bite severely when irritated; it is voracious, feeding upon fish, frogs, insects, and even its own species, which it seizes with a sudden movement of the head; after eating, it generally fasts a week or two, and it is less voracious in winter than in summer; it is able to endure extremes of heat and cold, and has a remarkable power of reproducing lost parts; on land its motions are very awkward and slow. This species is confined to the lakes and streams of the high mountains of Nippon, between lat. 34° and 38°; some other parts of Japan and parts of China; it is employed by the native physicians, in the form of food, as a preservative against contagious diseases and as a remedy in pulmonary complaints. There has been for some years a living specimen in the zoological gardens in London. The remains of the gigantic salamander found in the tertiary fresh-water formations of Oeningen, formerly regarded as fossil human bones, the homo diluvii testis of Scheuchzer, are referred to this genus by Van der Hoeven, under the name of C. primigenius; in size, form, and structure it comes near to the Japanese species, and is one of the most interesting of the antediluvian animals which inhabited the fresh waters of Europe. The famous footprints of Hildburghausen, Germany, on which was established the cheirotherium of Dr. Kaup, have also been referred to a similar salamandroid batrachian. (See Labyrinthodon.)

MENSES. See Catamenia.

MENSHIKOFF. I. Alexander Danilovitch, prince, a Russian statesman, born in Moscow about 1672, died in Berezov, Siberia, Nov. 2, 1729. The son of poor parents, he was brought up without education, and apprenticed to a baker; but having entered the service of Peter the Great, he commended himself to his patron’s favor by discovering a conspiracy among his guards. He served in the campaign of Azov, accompanied the czar to Holland and England, and on the death of Lefort became his principal adviser, being equally active in preparing or executing the great schemes of national re-form, and in the warlike and diplomatic operations against Charles XII. He distinguished himself at the siege of Schlüsselburg in 1702, and was made major general and governor of Ingria in 1704. During the campaign of 1706 he gained the decisive battle of Kalisz over the Swedes. He was made a prince both of the German empire in 1706, and of Russia in 1707. In 1709 he greatly contributed to the victory of Pultava, and was made a field marshal; in 1710 he commanded the Russian forces in the north, and took Rigas; in 1711 he occupied Courland, and was made governor of St. Petersburg; in 1712 he occupied Pomerania, and in 1713 took Stettin. Hisupidity led him to commit numerous arbitrary acts, for which he was finally court-martialled and sentenced to death, but escaped with a heavy fine. He regained his influence under Catharine I. (1725–77), of whose accession to the throne he was the principal instrument, and till her death exercised full sway over Russia. He was still more powerful at the beginning of the reign of the young Peter II., whose father-in-law he was about to become when he was suddenly arrested through the influence of Dolgoruki (September, 1727), and banished with his family to Siberia. He at first bore his misfortunes with great firmness, but the loss of his wife and eldest daughter broke his spirit and hastened his death. The remaining members of the family were recalled in 1780 by the empress Anna. II. Alexander Sergeyevitch, prince, a Russian soldier, great-grandson of the preceding, born in 1789, died May 3, 1869. He entered the imperial service in 1805, was for some time attached to the embassy at Vienna, accompanied Alexander I. as aide-de-camp du-
ring the campaigns of 1812-14, and was promoted to the rank of general, but resigned in 1823, when the czar abandoned the cause of the Greeks. Under Nicholas he served as ambassador in Persia, as well as in the war with that country which broke out on his return, and soon after in the Turkish war of 1828-9. He took Anapa, was seriously wounded before Varna, and subsequently devoted himself to the restoration and development of the Russian navy, being appointed governor general of Finland in 1831, admiral in 1834, and minister of marine in 1836. In 1838 he was sent to Constantinople, to urge the claims of Nicholas in the affairs of Turkey. His extravagant behavior promoted a speedy rupture; he returned to Russia, and war was declared. The first victory of the Russians over the Turkish fleet at Sinope is attributed in part to Menshikof's previous reconnoiters in Turkey. Commanding both the land and naval forces in the Crimea, he lost the battle of the Alma, but strengthened the fortifications of Sebastopol, sacrificed a part of the fleet to bar the entrance of the harbor, and, though he lost another battle at Inkerman, distinguished himself by the utmost energy in defence of the fortress. He fell ill and was superseded by Gorchakov in March, 1855, and was appointed by Alexander II. commander of Cronstadt, whence he was recalled to St. Petersburg in April, 1856. He was among the staunchest members of the national or old Russian party, and was opposed to all reform.

MENSURATION, the art of measuring things which occupy space. This is the art which led to the formation of the science of geometry; and some schools of philosophy at the present day are inclined to limit the whole domain of mathematics to the field of mensuration, while extending this field so as to include time as well as space. The art is partly mechanical as well as mathematical, and even in its mathematical part is but the application or illustration of sciences that in their purity have no connection with material things.—There are three kinds of quantity in space, viz., length, surface, and solidity; and there are three distinct modes of measurement, viz., mechanical measurement, geometrical construction, and algebraic calculation. For the last two modes arithmetical computation is a necessary adjunct; for the ratio to a unit quantity can be definitely stated in particular cases only as a numerical ratio. Lengths are measured on lines, and the measure of the length of a line is the numerical ratio which the line bears to a recognized unit of length, the inch, foot, or mile, determined in England and in this country by reference to metallic rods three feet long, kept by the governments as standards. The mechanical mode of determining lengths is called direct measurement. Rods are directly compared with the standard, and accurately made of the same length, and these rods, "rules," or yard sticks, or else tapes and chains accurately graduated by direct comparison with such rules, are stretched side by side with the line to be measured, and the ratio observed. When the line is long and the rule is applied many times consecutively, the slight errors arising at the joining of the successive positions of the rod, being multiplied, become of serious practical importance. In geodesy, therefore, when base lines several miles long are to be accurately determined by direct measurement, an apparatus is used in which bars of different metals counteract each other's expansion and contraction. When the line is long, or when it is inaccessible, the length is usually measured by the second or third mode.

The measurement of a line by geometrical construction is effected by the direct measurement of accessible lines and angles in a figure of which the line to be measured forms a component part, and then drawing this figure upon paper, on a definite scale of a certain number of feet to the inch. The direct measurement of the unknown side upon the paper will evidently give the length of the line represented by it. Thus, if one ship has sailed 50 miles E., and another from the same port 100 miles 30° E. of S., and we wish to know their distance apart, we may draw a line one inch long and a line half an inch long, making an angle of 60° with each other, and we shall find their extremities separated by 868 of an inch, showing the ships to be 80-6 miles asunder. We do not include angles among quantities in space. Strictly an angle is a quantity, since it can be measured, and its measurement is necessary at times for the measurement of other quantities. But the measurement of angles is not, in the general use of language, included among the direct objects of mensuration. The measurement of a line by algebraic computation is effected as in geometrical construction, except that instead of drawing the figure we calculate the length of the unknown side from the known relations of the sides and angles of figures, and from tables giving numerical values for those relations in right triangles, into which all plane figures can be divided at pleasure. In practice, it is easier to measure angles with great accuracy than long lines, and hence in geodesy only one base line is actually measured, while all the other distances of the survey are computed from the measurement of the angles in a network of triangles. The second kind of quantity to be measured is surface. The area of a surface is its numerical ratio to a square surface whose side is a linear unit, that is, to a square foot, square inch, &c. This sort of measurement is never done directly or mechanically, but always by the measurement of lines, and generally by the use of the geometrical propositions, that all surfaces may be resolved into triangles; that all triangles are equivalent to the halves of rectangles having the same base and altitude; and that the area of a rectangle may be found by multiplying the number of units in its length by that
in its breadth. The reduction of all surfaces to subjection to these propositions requires sometimes so much labor, that in surfaces of a more intricate form use is made of algebraical laws and of the differential calculus, according to the fundamental idea of fluxions, that a surface is generated by a moving line which constitutes, in two positions, two of the boundaries of the surface. Thus a circle may geometrically be considered as composed of an unlimited number of triangles with their bases on the circumference and their vertices in the centre; or it may be considered algebraically as generated by a chord sweeping across it, beginning of no length, swelling to a diameter through the centre, and contracting again to zero. Either of these modes of viewing it leads to the same area of the circle, viz., the product of its circumference by half its radius, or, what is the same thing, \(78539\) of the square enclosing it.—The third species of quantity is solidity. The unit of measurement is here either a cube whose edge is a linear unit, or else it is an arbitrary number of cubic inches selected as a unit, such as the bushel of 2,150 inches, or the gallon of 281 inches. The direct or mechanical measurement of solidity is applied to liquids, or to solids separated into parts so small as to be handled somewhat in the manner of a liquid, as corn, for example, is poured from a basket. This direct measurement consists then in filling a vessel of known capacity with the article to be measured, repeatedly, until all is measured. The geometrical and algebraical modes of measuring solidity will be understood from the analogous modes of measuring lines and areas. They are principally based on the doctrines, that the solidity of a right parallelepiped is found by multiplying the area of its base by its altitude; that a pyramid has one third the solidity of a parallelepiped of the same base and altitude; and that every solidity can be divided into pyramids and parallelepipeds. But in intricate cases it is easier to use fluxions, and consider the solid generated by the motion of a surface through it; a hemisphere, for example, might be considered as an unlimited number of pyramids with their apices at the centre, or as generated by the circular plane of its base, diminishing as it rose to the summit of the hemisphere, and there becoming a point. Mechanic use arithmetical rules or formulas derived from considerations such as we have here presented. The cask or barrel, for example, is treated as though one of several varieties of geometrical solids, and rules are given for discovering its solidity on those suppositions. The gauge rod is marked with the number of gallons which a cask of certain form would have if its diagonal distance from the centre of the bung to the inner end of the staves were the same as from the end of the rod to the spot where that number is engraved; and thus by thrusting the rod diagonally into the bung hole of an ordinary cask, the number of gallons it contains is readily determined. The tonnage of ships is computed in the same way by assuming the figure of the ship to be of a certain model, and the tonnage is therefore over-estimated according to its departure from this average form. Many works have been published containing only practical rules without explanation, all essentially alike. In particular cases, ingenuity may devise particular modes for measuring the solidity or the area of very complicated figures; the earliest example is that of Archimedes determining the solidity of Hiero's crown by plunging it into water to discover how much of the fluid it displaced. Another example is Galileo's determination of the area included between a cycloid and its base by describing the cycloid upon a plate of metal, cutting it out, and comparing its weight with that of the generating circle cut out of a similar plate.

**Menchikoff.** See Menshikoff.

**MENTONE** (Fr. Menton), a town of France, in the department of Alpes-Maritimes, on the gulf of Genoa, 12 m. N. E. of Nice; pop. about 10,000. It is on two small bays, called respectively the East and the West bay, which are separated by a point of land, and is shut in on the land side by a semicircular range of mountains from 3,000 to 4,000 ft. high. Mentone has one of the mildest climates on the Ligurian seaboard, and is a place of much resort in winter, especially by consumptives. Ample provision is made for the accommodation of visitors. The old town, situated chiefly on the point dividing the bays, is well built and clean; it contains a castle and a communal college. In the suburbs are elegant villas, and the lower hills in the background are covered with olive groves and plantations of oranges and lemons. In the middle ages Mentone formed a part of the principality of Monaco, whose rulers were feudatories of Piedmont. Though swept away by the French revolution, the princes of Monaco were recognized at the congress of Vienna. In 1848 the inhabitants of Mentone and the neighboring Rocabruna rebelled, and annexed their places to Sardinia. Prince Florestan protested, but after the cession of Nice to France in 1860 renounced his rights for a pecuniary compensation (Feb. 2, 1861).—At the E. extremity of the East bay are the celebrated bone caves of Mentone, which have furnished an abundance of interesting organic and other prehistoric remains. These caves, which are about 88 ft. above the Mediterranean, are natural rifts in the Roches Rouges, the mountain over which the Cornice road passes. On March 26, 1872, a fossil human skeleton was exhumed in one of them, at a depth of 213 ft. from the surface. It lay on its left side in a natural posture, as if death had overtaken the man during sleep. The skull is ornamented with a number of shells, and with 22 canine teeth of the stag, all of which are perforated and form a kind of network about the head. The skeleton, which is
nearly perfect, and indicates great strength, was placed in the museum of natural history in Paris. It is supposed to belong to the palaeolithic age. The cranium is fractured behind and in front, so as to prevent perfect measurement. It is dolichocephalous, arched at the summit, and the sutures are all consolidated. The facial angle is nearly 85°. The height of the man is estimated to have been six feet.

MENTOR, in Homer's Odyssey, the son of Alcimus, and friend of Ulysses, who intrusted to him the charge of his house on his departure from Ithaca. To him fell the care of young Telemachus, and Minerva assumed his form in accompanying the latter on the journey in search of his father, acting the part of a wise counsellor. On the return of Ulysses, Mentor assisted in the contest with the suitors, and brought about a reconciliation between him and his people. The name is applied metaphorically to any sage adviser or monitor.

MENTZ (Ger. Mainz; Fr. Mayence; ane. Moguntiacum), a fortified city of Germany, capital of Rhenish Hesse, on the left bank of the Rhine, nearly opposite its junction with the Main, 20 m. W. S. W. of Frankfurt, with which it is connected by railway, and within a few miles of Wiesbaden; pop. in 1871, inclusive of the garrison, 53,918. A bridge of boats 1,700 ft. long connects it with the village of Castel on the opposite bank of the Rhine, and a costly railway bridge, erected in 1862, connects it with the opposite side of the Main. The system of fortification is extensive and elaborate, controlling both sides of the Rhine, and consisting of a double line of wall, with bastions and outworks, and citadel in the centre. The town rises from the river in the form of an amphitheatre. The houses are generally lofty, and many of the streets are narrow and confined. Of late years a better system of building has prevailed, and there are several handsome squares. The Gutenberg-Platz contains a monument to Gutenberg, who was born and died in Mentz, with a statue by Thorwaldsen, and the Schiller-Platz has a bronze statue of the poet. There are 11 churches, including the church of St. Ignatius, the ceiling of which is adorned with paintings from the life of the saint; and the cathedral, founded in the 10th century and rebuilt in the 14th, of little architectural merit, but having fine painted windows and a beautiful pulpit. It suffered greatly during the siege of 1798, and of its treasures and famous library nothing is left; but it contains the monuments of several of the archbishop-electors of Mentz. The old electoral palace, restored in 1844, contains the town library of 120,000 volumes, a picture gallery, and a fine museum of Roman antiquities. There are Roman remains in and near Mentz, which was a Roman camp under Drusus; among them are the Eichelstein, a great stone on one of the bastions of the citadel, which has been
thought to be a monument of Drusus, and the pillars of an aqueduct and the pines of a bridge supposed to have been built by him. A remarkable fragment of Roman statuary was found here in March, 1874. The site of the house of Gutenberg is occupied by the casino, or reading room, and the rooms of a literary association. The house in which he was born is still standing, and that also which contained his first printing press. The trade up and down the Rhine and the Main, and by the railway, is increasing continually. The manufactures are not very important; they consist mostly of leather, tobacco, soap, pianofortes, hats, glue, and vinegar.—The city was a place of importance under the Romans, and was destroyed by the barbarians in 406. It was rebuilt by the Frankish kings, and enlarged by Charlemagne. Under St. Boniface it became the seat of an archbishop. Under the German empire the archbishop of Mentz ranked first among the three ecclesiastical electors, and held the dignity of arch-chancellor. The electorate, which originally did not embrace the city of Mentz, had extensive possessions on both sides of the Rhine, eventually including Erfurt and Eichfeld. In the 13th century Mentz stood at the head of the league of the Rhenish towns. Through Gutenberg it became the centre of bookmaking. In 1486 it was annexed to the electorate. During the thirty years' war, it was taken by the Swedes in 1631, by the imperialists in 1636, and by the French in 1644. After the peace of Westphalia it was restored to the elector John Philip, who strengthened the fortifications; but it was again taken by the French in 1688, and retaken by the Saxons and Bavarians in 1689. It was betrayed to the French general Custine in 1792, but was reduced by the Prussians under Kalkreuth in 1793. By the peace of Lunéville (1801), which dissolved the electorate (see DABERG), Mentz was allotted to France, but by the congress of Vienna (1814) to the grand duke of Hesse-Darmstadt, as a fortress of the German confederation, to be garrisoned by a mixed force of Austrians, Prussians, and Hessians, the offices being divided between Austria and Prussia. In the spring of 1848 disturbances among the people led to a riotous and bloody strife, May 21, between the citizens and the Prussian soldiers; but the difficulties were adjusted by a commission from the German national assembly. On Nov. 18, 1857, a military magazine blew up, destroying an entire street, with many lives and much property. On the outbreak of the Austro-Prussian war in 1866, the Austrians and Prussians left the fortress, which was garrisoned by the Hussian troops alone. After the conclusion of peace the Prussians returned, and secured the sole right of garrison. In 1871 it became one of the fortresses of the German empire. It has a garrison of 8,000 men. In February, 1873, it was proposed to remodel the fortifications. Mentz is one of the chief centres of the Catholic societies of Germany, and in June, 1874, it was made the permanent seat of the Catholic association, whose object is the support of the pope and the bishops against the imperial government.

MENZEL, Adolf Friedrich Erdmann, a German painter, born in Breslau, Dec. 8, 1815. He assisted his father as a lithographer, illustrated Kugler's popular history of Frederick the Great (1839—42), and prepared designs for Frederick's writings (1840—57). In 1850 he exhibited his first oil painting, "Frederick the Great and his Friends." In 1865 he finished his "Coronation of King William I. at Königsberg." Many of his genre pictures appeared in 1870, and also his "Departure of the King for the Seat of War in France."

MENZEL, Kari Adolf, a German historian, born in Grünberg, Silesia, Dec. 7, 1784, died in Breslau, Aug. 19, 1855. He studied at Breslau and Halle, and officiated for many years as professor at Breslau. He wrote Topographische Chronik von Breslau (2 vols., Breslau, 1800—7); Geschichte Schlesiens (2 vols., 1807—10); Die Geschichte der Deutschen (8 vols., 1815—28); Die Geschichte unserer Zeit seit dem Tode Friedrichs II. (2 vols., 1824—5); Neuere Geschichte der Deutschen von der Reformation bis zur Bundesakte (16 vols., 1826—56); and Staats- und Religions-Geschichte der Königreiche Israel und Juda (Breslau, 1853).

MENZEL, Wolfgang, a German author, born at Waldenburg, Silesia, June 21, 1798, died in Stuttgart, April 23, 1873. He began his studies at Breslau, served as a volunteer in the war of 1815, and subsequently studied at Jena and Bonn. In 1820 he went to Switzerland, and engaged in teaching. About this time he became known as a writer of poems and literary criticisms. His first publication was his Streckverse (Heidelberg, 1823). In 1825 he established himself at Stuttgart. After the revolution of 1830 he zealously opposed French political and literary influence in Germany, and was repeatedly elected to the Württemberg diet. Börne satirized him in his Menzel der Franzosenfresser. He edited for many years the literaryblatt of Stuttgart, gave it up in 1848, but revived it in 1852, and made it an organ of reactionary policy in civil and ecclesiastical matters. Besides the writings mentioned above, he published Geschichte der Deutschen (3 vols., Zürich, 1824—5; translated into English by G. Horrocks, London, 1849); Die deutsche Literatur (Stuttgart, 1828; translated into English by C. C. Felton, in Ripley's "Specimens of Foreign Literature," Boston, 1840); Kühnezahl (1829); Narceus (1830); Reise nach Osterreich (1831); Reise nach Italien (1835); Taschenbuch der neuesten Geschichte (5 vols., 1829—33); Geist der Geschichte (1835); Europa im Jahre 1840 (1839); Mythologische Forschungen und Sammlungen (1842); Die Gesänge der Völker (1851); Furor, a novel descriptive of scenes of the thirty years' war (Leipzig, 1851); Geschichte Europas von 1759—
1815 (2 vols., Stuttgart, 1855); Geschichte der letzten 40 Jahre (2 vols., 3d ed., 1865); Preußen und Oesterreich im Jahre 1866 (1866); Geschichte des französischen Krieges von 1870 (1871); Rom's Unrecht (1871); Geschichte der neuesten Jesuitenumtriebe in Deutschland 1870–72 (1873); and Kritik des modernen Zeitbewusstseins (2d ed., 1874). His library was purchased by the German government in 1874 for the university of Strasbourg.

Mephistopheles, in old popular legends, the familiar spirit of the magician Faust, the second of the fallen archangels, and the most powerful chief of the infernal legions after Satan. The name is by some derived from the Greek μῆθη, not, φῶς, light, and ψως, loving. He is chiefly known as the malignant, scoffing fiend of Goethe’s “Faust.”

Méquinez, or Miknas, a city of Morocco, in the province of Fez, near the Seboö, 36 m. W. S. W. of Fez; pop. about 70,000. It is situated in a valley of a mountainous district, and is surrounded with triple walls. Most of the houses are one story high, but are neat and substantial. The principal buildings are several mosques, a castle founded in 1674 by Sultan Muley Ismail, and a palace which is occasionally the residence of the sovereign, adorned with marble columns, fountains, and fine gardens. There are manufactures of painted crockery and leather. In the vicinity are large plantations of olives. There is an extensive trade at Méquinez in most of the products of the country.

Méjadante, Saverio, an Italian composer, born in Altamura in 1797, died in Naples, Dec. 18, 1879. At the age of 12 he entered the royal college of music at Naples, and studied the violin and flute, but soon devoted himself to the study of dramatic art and to composing for the voice. In 1818 a cantata of his composition was performed at the theatre Del Fondo, and for 25 years he wrote opera after opera with great rapidity, many of them meeting with no success. In 1833 he became chapelmaster at the cathedral of Novara. In 1836 his opera I Briganzi was brought out at Paris, but failed even with such great singers as Rubini, Tamburini, Lablache, and Grisi. In 1840 he became director of the royal conservatory at Naples, but his sight failed him, so that in 1862 he became completely blind, and was obliged to dictate whatever he composed. Of his 40 odd operas II giuramento is now best known.

Mercator, Gerard, a Flemish geographer, born at Rupelmonde, March 5, 1512, died in Duisburg, Dec. 3, 1594. He learned engraving, and Charles V. employed him on maps. In 1559 he was appointed cosmographer to the duke of Juliers and Cleves. He published descriptions and maps of Europe, France, Germany, the British isles, and the world. His method of laying down charts and maps, by a projection of the surface of the earth in plano, is still in use. The most important of his works are: Chronologia a Mundi Eorolani ad 1568 (Cologne, 1569); Tabula Geographica ad Mon-tem Ptolemai restituta (1578); De Creatione ac Fabrica Mundi, a treatise prefixed to the uniform edition of his maps (1594); and Atlas sive Geographicae Meditationes de Fabrica Mundi et factiici Fabrica (Duisburg, 1595).

Mercer, a central county of California, intersected by the San Joaquin river, and watered by the Mercer and Mariposa, its tributaries; area, 1,975 sq. m.; pop. in 1870, 2,807, of whom 166 were Chinese. It is bounded W. by the Coast range. The soil is very fertile. It is traversed by the Visalia division of the Central Pacific railroad. The chief productions in 1870 were 218,162 bushels of wheat, 14,456 of Indian corn, 142,436 of barley, 13,830 of Irish and 11,330 of sweet potatoes, 231,072 lbs. of wool, 232,530 of butter, 229,298 of cheese, and 8,195 tons of hay. There were 2,362 horses, 49,531 cattle, 46,525 sheep, and 9,054 swine. Capital, Snelling.

Mercer, the name of counties in eight of the United States. I. A. W. county of New Jersey, bordering on Delaware river; area, 260 sq. m.; pop. in 1870, 46,306. The earth is unven, and somewhat elevated toward the N., and the soil is fertile. It is traversed by the New Jersey, the Camden and Amboy, the Belvidere and Delaware, and the Mercer and Somerset railroads, and the Delaware and Raritan canal. The chief productions in 1870 were 149,238 bushels of wheat, 545,547 of Indian corn, 428,143 of oats, 222,207 of potatoes, 17,516 lbs. of tobacco, 25,425 of wool, 500,342 of butter, and 28,767 tons of hay. There were 4,464 horses, 6,601 milch cows, 3,529 other cattle, 9,384 sheep, and 6,758 swine; 4 manufactories of agricultural implements, 1 of freight and passenger cars, 21 of men's clothing, 4 of ground coffee and spices, 1 of cotton goods, 3 of woolen goods, 1 of drugs and chemicals, 65 of wagon materials, 8 of India-rubber and elastic goods, 5 of forged and rolled iron, 2 of nails and spikes; 6 of iron castings, 7 of machinery, 1 of lead and zinc, 9 of sash, doors, and blinds, 14 of stone and earthen ware, 1 of wire work, 8 saw mills, and 15 flour mills. Capital, Trenton.

II. A. W. county of Pennsylvania, bordering on Ohio, drained by the Shenango and several smaller creeks; area, 624 sq. m.; pop. in 1870, 49,977. The surface is undulating and the soil fertile. Extensive coal mines are found, also iron and limestone. It is traversed by the Atlantic and Great Western railroad, the Erie and Pittsburgh, the Shenango and Allegheny, and the Franklin division of the Lake Shore; also by the Beaver and Erie canal. The chief productions in 1870 were 341,922 bushels of wheat, 24,850 of rye, 639,743 of Indian corn, 883,965 of oats, 68,625 of buckwheat, 149,124 of potatoes, 618,432 Ibs. of flax, 246,699 of wool, 1,516,067 of butter, 101,560 of cheese, and 58,492 tons of hay. There were 11,390 horses, 15,570 milch cows, 18,489 other cattle, 68,038 sheep, and 15,414 swine; 38 manufactories of carriages and wagons, 1 of dressed flax, 8 of forged and rolled iron, 2 of
nails and spikes, 15 of iron castings, 9 of machinery, 13 tanneries, 3 breweries, 52 saw mills, 9 planing mills, 20 flour mills, and 5 woolen mills. Capital, Mercer. III. A S. county of West Virginia, bordering on Virginia, bounded E. by the Kanawha and intersected by Bine-
stone river; area, 540 sq. m.; pop. in 1870, 7,064, of whom 394 were colored. A range of the Alleghenies extends along the N. W. bor-
der. The chief productions in 1870 were 25,-756 bushels of wheat, 5,597 of rye, 114,746 of Indian corn, 48,184 of oats, 10,867 of potatoes, 117,429 lbs. of tobacco, 18,713 of wool, 109,355 of butter, and 2,617 tons of hay. There were 1,067 horses, 2,722 milk cows, 3,105 other cattle, 8,295 sheep, and 6,554 swine. Cap-
ital, Princeton. IV. A central county of Ken-
tucky, bounded N. E. by Kentucky river, and E. by Dick's river, and drained by the head waters of Salt river; area, 240 sq. m.; pop. in 1870, 13,144, of whom 3,310 were colored. The surface is undulating and the soil fertile. The chief productions in 1870 were 146,584 bushels of wheat, 23,941 of rye, 496,775 of Indian corn, 66,001 of oats, 14,551 of potatoes, 33,584 lbs. of wool, 125,042 of butter, and 2,992 tons of hay. There were 7,735 horses, 2,250 milk cows, 3,753 other cattle, 7,684 sheep, and 18,349 swine; 3 manufactories of carringages and wagons, 2 of woolen goods, 1 saw mill, and 2 flour mills. Capital, Harrodsburg. V. A W. county of Ohio, bordering on Indiana, drained by the St. Mary's and Wabash rivers and branches; area 576 sq. m.; pop. in 1870, 17,254. It has a level surface heavily timbered, and a fertile soil. The chief productions in 1870 were 338,189 bushels of wheat, 341,775 of Indian corn, 244,289 of oats, 94,298 of pota-
toes, 12,889 of flax seed, 94,742 lbs. of wool, 373,656 of butter, and 16,577 tons of hay. There were 5,518 horses, 5,816 milk cows, 6,765 other cattle, 26,669 sheep, and 24,946 swine. Capital, Celina. VI. A N. W. county of Illinois, separated from Iowa by the Missis-
sippi; area, 550 sq. m.; pop. in 1870, 18,768. There are extensive prairies in the county, and it is heavily timbered along the banks of the Mississippi; the soil is fertile. The Galva and Keithsburg branch of the Chicago, Burlington, and Quincy railroad passes through it. The chief productions in 1870 were 302,494 bushels of wheat, 40,778 of rye, 2,054,962 of Indian corn, 452,889 of oats, 94,241 of potatoes, 52,-088 lbs. of wool, 376,727 of butter, and 28,180 tons of hay. There were 10,984 horses, 7,655 milk cows, 15,552 other cattle, 11,278 sheep, and 41,663 swine; 13 manufacturies of carri-
gages, 7 of saddlery and harness, 9 flour mills, and 1 saw mill. Capital, Aledo. VII. A N. county of Missouri, bordering on Iowa, and drained by the Weldon river; area, 530 sq. m.; pop. in 1870, 11,557, of whom 95 were colored. It has an undulating surface and fertile soil. It is trav-
ersed by the Chicago, Rock Island, and Pa-
fic railroad. The chief productions in 1870 were 69,068 bushels of wheat, 472,730 of Indian corn, 160,681 of oats, 42,969 of potatoes, 17,550 lbs. of tobacco, 57,000 of wool, 234,074 of but-
ter, and 11,662 tons of hay. There were 5,153 horses, 4,416 milk cows, 8,342 other cattle, 25,441 sheep, and 19,927 swine. Capital, Prince-
ton. VIII. A N. W. county of Dakota, bounded N. and E. by Missouri river; area, about 900 sq. m. It is intersected by the Big Knife and other affluents of the Missouri. It has been re-
cently formed, and is not included in the cen-
sus of 1870. The surface is rolling, and the soil moderately fertile.

MERCER, Hugh, an American revolutionary soldier, born in Scotland about 1720, died near Princeton, N. J., Jan. 12, 1777. He was educated as a physician, and served as a surgeon's assistant in the army of the young pretender at Culloden. He soon after settled in Virginia, and in 1755 served in the French and Indian war and volunteered in the expedition led by Braddock to Fort Duquesne. At the battle of Monongahela, July 9, he was wounded in the shoulder, and wandered alone through the wilderness to Fort Cumberland, 100 m. distant. He returned to his practice, and was residing in Fredericksburg at the outbreak of the revolu-
tion, when he was commissioned colonel of one of the regiments authorized in 1775 by the Virginia convention, and through the influence of Washington obtained the rank of brigadier general with the command of the flying camp organized in the spring of 1776. He accompanied Washington on his retreat through New Jersey, and rendered valuable assistance at the battle of Trenton. In the succeeding action at Princeton he led the vanguard, composed prin-
cipally of militia. His men beginning to waver before the attack of the enemy, he made an energe tic attempt to rally them, and was fallen to the ground by a blow from the butt end of a musket. Though surrounded by British sol-
diers, he rose and defended himself with his sword, refusing quarter, and after a brief struggle, in which he was repeatedly bayo-
ned, was left for dead upon the field. He was removed soon after the battle to a house in the neighborhood, where about a week after ward he died. His corpse was followed to the grave in Philadelphia by upward of 30,000 people. In November, 1840, a monument to his memory was dedicated at the Laurel Hill cemetery. Provision was made by congress for the education of his youngest son.

MERCERSBURG, a borough of Franklin co., Pennsylvania, at the terminus of a branch of the Cumberland Valley railroad, 15 m. S. W. of Chambersburg and 62 m. S. W. of Harris-
burg; pop. in 1870, 971. It is the seat of Mecersburg college (Reformed), organized in 1865, and having in 1873-4 6 professors, 3 tutors, 50 preparatory, 45 collegiate, and 9 theological students, and a library of 2,000 volumes. The theological department was or-
ganized in 1872. Marshall college and the theological seminary of the Reformed church, formerly situated here, have been removed to
Lancaster, the former in 1853 and the latter in 1871. The college was merged with Franklin college, and is now known as Franklin and Marshall college.

MERCHANT, Commission. See Factor.

MERCIA, the largest kingdom of the Saxon heptarchy in the island of Britain. The name is derived from mark, meaning frontier, as this was the most western of the three kingdoms of the Angles. It was situated inland, being bounded N. by Cumbria and Northumbria, E. by East Anglia and Essex, S. by Wessex, and W. by Wales, and included the modern counties of Chester, Derby, Nottingham, Lincoln, Salop, Stafford, Leicester, Rutland, Northampton, Huntingdon, Hereford, Worcester, Warwick, Gloucester, Oxford, and Buckingham, and parts of Hertford and Bedford. It was founded by Crida, an Angle, about 585, was subject for a time to the Northumbrians, and afterward subdued East Anglia and Kent. Its more important kings were Penda, Ethelred, Kenred, and Wiglaf, who was finally conquered by Egbert, king of Wessex, in 827.

MERCII, Johann Heinrich, a German scholar, born in Darmstadt, April 11, 1741, died June 27, 1791. He officiated in various public functions in his native town, translated Addison's "Cato" and other works from the English, cooperated with Lavater in the publication of his work on physiognomy, and took an active part in the Frankfurter gelehrte Anzeigen, Deutscher Merkur, and other leading periodicals, and in various other literary enterprises. His select works were edited long after his death by Stahr, and published in Oldenburg in 1840. He is chiefly remembered in German literature on account of his intimate association with Goethe, Herder, and other eminent men, upon whose intellectual development he exerted a great influence by his literary criticism. The latter part of Merck's life was saddened by domestic and pecuniary misfortunes, which led him to shoot himself. The letters addressed to him by Goethe, Herder, Wieland, and others, were published by Wagner (Darmstadt, 1835); and another edition of his correspondence, including both letters received and written by him, appeared in 1838.

MERCURY, or Quicksilver, a metal of the color and lustre of silver, and fluid at ordinary temperatures, whence its ancient name of argenteum venum, and that by which it was called by Aristotle and Theophrastus, who made the earliest mention of it, ἀργυρός χρύς, fluid silver. It was also known as hydromercury, and from this its chemical symbol, Hg, is derived. The equivalent of the metal is 200; and its specific gravity, which varies somewhat with the temperature, is given by Kopp as 13.557 at 62° F. At 39° or below zero F. the metal becomes solid and crystallizes in regular octahedrons, contracting in bulk and assuming the density of 14; the mass is malleable, and resembles lead. Its boiling point is 632° F., at which it forms an invisible, transparent vapor, the density of which is 6,976, air being 1,000. Before assuming this form, if exposed to the air at high temperatures, it absorbs oxygen and is converted into the red oxide, which is decomposed at the boiling point. Above 40° F. mercury is somewhat volatile, as may be shown by holding an iodized daguerreotype plate, that has been submitted to the action of light in the camera, over a bath of mercury, when the picture will be brought out by the vapor. Gold leaf is also affected by the vapor when suspended in a vial containing mercury and kept at ordinary temperatures. Strong nitric acid dissolves mercury; but hydrochloric acid, hot or cold, does not affect it. It is oxidized by heated concentrated sulphuric acid, and is soluble in a solution of common salt. Exposed for a long time to the air, mercury gathers a film of gray oxide upon its surface, which adheres to the glass in which the metal is contained; glycerine is employed to prevent the formation of this film. When mercury contains dissolved in it lead, zinc, or other extraneous oxidizable metals, these may be removed by covering the surface of the metal, placed in a shallow vessel, with dilute nitric acid, and stirring frequently. The acid attacks and takes up the foreign matters, and may also form a crust of nitrate with a small portion of the mercury. This is a more efficient method of purification than that of distillation when zinc is present, as this is distilled over with the mercury. Impurities mechanically mixed with mercury may often be removed by straining the metal through paper perforated with a very small hole, or squeezing it through wash leather. But if a film of oxide still adheres to the mercury, this may be removed by agitating it violently in a bottle in which some powdered white sugar has been introduced, then blowing air into the bottle, repeating the shaking and blowing several times, and then filtering. Mercury unites with various metals, as gold, silver, tin, lead, zinc, and bismuth, forming compounds which are noticed under the head of amalgam. In some cases the cheapest of the metals named have been used to adulterate mercury. The effect of this mixture is to produce an amalgam, the presence of which is easily detected by the fluid, when poured upon a plate of glass or porcelain, not flowing freely, but leaving a trace behind it. — Mercury occurs native in globules scattered through masses of rocks or ore, and also (rarely) in the form of a silver amalgam; but chiefly as a sulphide of mercury. (See Cinnabar.) It seldom if ever occurs in fissure veins, though sometimes it impregnates or constitutes well defined deposits. It is found in geological formations of almost all ages, and particularly in talcose and argillaceous slates. The most important deposit in the world is that of Almaden in Spain, from which, according to Pliny, the Romans annually obtained about 700,000 lbs. of cinnabar. The matrix of the ore consists of quartz and quartzose sandstone, intermixed with cinnabar in
beds or intercalated veins, enclosed in slates and quartzites of upper Silurian age. A mass of ore nearly 100 ft. wide, called el Rosario, constitutes the largest development. The Span-

ish government holds the title and has leased the mines to the Rothschilds. The average yield of all the ore is about 7-85 per cent. (See Almaden.) The annual production of the Spanish mines was estimated in 1867 at about 2,500,000 lbs. At Idria, in Illiria, cin-

nabar occurs impregnating beds of limestone of uncertain age. (See Idria.) These mines are controlled by the government, and the product in 1871 was 750,400 lbs., and about 123,200 lbs. of artificial cinnabar. The material is very soft, sometimes contains globules of mercury, and gives off mercurial fumes which injure the health of the workmen. In the Palatinate quicksilver ores are found at moder-

ate depths distributed in the fissures of the rock apparently by sublimation. At Rips, in Modena, cinnabar impregnates micaceous and talcose slates. At Valt Alba, in Venetia, it occurs in the calcareous schists and in quartz-

ose porphyry. Native mercury is found at Montpellier in France, disseminated through tertiary marls and calcareous conglomerate. In Chili cinnabar is found in granitic rocks, and in Peru in sandstone associated with coal. The great Peruvian mines of Huancavelica were worked as early as 1566. The product down to 1845 was about 1,100,000 quintals of mer-

cury (101-60 lbs. each). Of this only 66,000 quintals were produced after 1789, up to which time Humboldt gives the production as 1,040-460 quintals, worth at the government price $75,854,297. The present annual production of Peru probably does not exceed 200,000 lbs. Mercury is found at many localities in Mexico, but is not extracted at present on a large scale. The great consumption of this metal in the patio process at the haciendas or metallurgical works of Mexico is supplied by importations from Spain and California.—The deposits of New Almaden, 12 m. from San José, in Santa Clara co., California, occur in the Coast range, in a belt of altered cretaceous slates, between beds of serpentine on either side. The ore is found in a series of irregular cavities occurring without apparent connection or order. The average yield of the ore worked in 1873 at New Almaden was 7-86 per cent. quicksilver; a large amount (something more than one half) of the material reduced in that year was tierras or poor earthy screenings, yielding 2 per cent. This reduced the general average to 4-87 per cent. The product of this property for 214 years, ending Dec. 31, 1873, was as follows:

<table>

(A flask contains 764 lbs.) The deposit at New Almaden was first found by Indians, who used the material as a paint, and excavated openings 50 or 60 ft. into the mountain in search of it. In 1824 and afterward the Spaniards attempted to work it for silver. In 1845 it was worked first for mercury by Capt. Castillo. Operations were suspended during the war, and recommenced in 1848, and a company of Mexi-

cans and English held the mine from 1850 to 1858, when they were enjoined, pending litigation as to title. The value of the product up to this time had amounted, according to legal papers, to over $8,000,000, and was estimated at $1,000,000 annually. The total value of the New Almaden property was rated by the United States attorney general at $15,000-

000. In the same neighborhood the Enri-

quita, Providencia, and Guadalupe mines have been worked. In Fresno county the New Idria series of mines, including the San Carlos, Au-

rora, Idria, Molino, Washington, Benada, and Victorener mines, contain cinnabar in sand-

stone and slate. The Panoche Grande, in this county, is famous in the records of litigation and litigation as the McGarrah claim. The Redington mine in Lake county is similar in formation to the New Almaden. The decrease of late years in the production of quicksilver in California, and the consequent rise in price, have led to numerous discoveries and new openings of mines in that state. The producing mines in 1873 are given as follows: New Almaden, 11,042 flasks; New Idria, 7,600; Red-

ington, 4,200; Great Western, 651; Manhat-

tan, 621; Summit, 75; American, 128; Napa, 199; California, 995; Phoenix, 860; Wash-

ington, 197. As the price of quicksilver had risen by the end of the year to $1 20 per pound, and had averaged during the year something over $1 per pound, the product of California in 1873 may be valued at more than $2,000,000. In quantity the production was less than that of previous years. California yielded in 1867, according to the reports of the Paris exposition, 3,960,000 lbs., out of a total for all coun-

tries of 7,082,120 lbs.—The methods employed in mining quicksilver ores present no peculiar features, except those which are incident to the great irregularity of the deposits. The theory of the reduction of the ores is simple. Pure cinnabar contains 12-72 parts of sulphur to 86-21 of quicksilver. The general average of the ores extracted is, however, less than 10 per cent. of quicksilver; in the majority of the deposits in California not over 2 per cent. Even much poorer ore is heated in retorts with 50 per cent. of its weight of lime or iron filings. The sulphur combines with the lime or iron, forming a non-volatile sulphide, setting free the mercury, the fumes of which
are then passed into condensers. By the second system the ore is burned in furnaces, where the sulphur is converted into sulphurous acid gas by the admission of air, and the quicksilver is set free as a vapor. All the vapors and gases from this combustion pass into condensing chambers, where the quicksilver is condensed, while the gases escape to the chimney. The retort system, although less wasteful in quicksilver, involves so much additional expense that it is not advantageous in practice. The roasting of cinnabar in furnaces is now universal. The furnaces used are of two general classes, intermittent and perpetual. In the former, a large charge is introduced, burned, and withdrawn when it has become cool, leaving the furnace ready for another. In a perpetual furnace small charges are continually introduced at stated intervals, and the burned ore is withdrawn without interrupting the process. Intermittent furnaces of different varieties are used at Almaden, Idria, and some points in California. A Spanish furnace at Almaden is peculiar in its system of condensation, by which the quicksilver is distilled in large numbers of clay crucibles joined together like pipes. The condensing chambers contain 508 of these in 12 rows of 44 each. Each Aludel, so called, is about 18 in. long, 10 in. wide in the middle, and 6 in. wide at each end, where it fits into the next. A small hole in each allows the condensed quicksilver to flow out into a gutter leading to a central channel. The furnace consists of a cylindrical shaft about 8 ft. in diameter and 26 ft. high, divided by perforated arches, 9 or 10 ft. from the top, into two compartments, the upper being for ore and the lower for fuel. The process of burning and distilling quicksilver lasts three days. On the fourth day the furnace is recharged, and the Aludels are taken up, emptied, and rearranged. The furnace used at Idria has a series of brick chambers separated by partition walls for condensing the quicksilver. The intermittent furnaces of California are also provided with brick condensers. The power which bricks have of retaining heat is one of the greatest objections to their use; another is the inevitable loss of quicksilver, which forces its way even through the best made bottoms of condensing chambers, and through imperceptible cracks in the walls. The furnaces of California are built upon arches, and near the bottom of these arches pieces of sheet iron are placed in the masonry, which catch the quicksilver as it filters through, and conduct it to a basin. The merit of brick condensers as compared with iron lies in their ease of construction and repair, and in their indifference to the sulphuric acid which is formed with the sulphurous acid gases in contact with steam and oxygen. The intermittent furnaces at New Almaden are 40 ft. long, 8 ft. wide, and 10 ft. high, each being divided into compartments, the fire occupying one at the end, and the heat passing through the ores into flues. A charge of 18,000 lbs. is worked in 60 hours with wood fuel. A flue from the furnace passes upward to the first condensation chamber, which is 8 ft. long, 4 ft. broad, and 5 ft. high. The chambers are covered with cast-iron plates luted down. After passing through eight chambers the remaining vapors are conducted into a tank, where they are sprinkled with water, and thence escape by wooden chimneys. The ore is usually so mixed for treatment as to present a uniform low percentage. The finer fragments are worked up with the soft loamy portion, and the mass is kneaded with water and moulded into bricks, which being dried in the sun are worked like the rest. A great saving of fuel may be effected by the use of perpetual furnaces, or of kilns such as are employed for roasting iron ore or lime. Of this class are the Alberto furnaces, which is a reverberatory, and hence suitable for small-sized pieces only; the Hübner, Fult, and Vail Alta, which are shaft furnaces employed in Europe; and the furnaces of Riotte, Knox, and Porslècker, which are California improvements. Cast-iron, wooden, or wooden and sheet-iron tanks, or iron tubes, are employed as condensers. Draft is obtained by means of suction fans. From 20 to 24 tons of ore is passed through a perpetual furnace daily, every ton remaining in the furnace nine hours above the fire bridge, and an additional time of three to four hours below the fire bridge in the hottest portion of the furnace, where the last particles of quicksilver are expelled. The great subtlety with which the vapors of this metal penetrate through the minutest openings is well known to workmen at quicksilver furnaces. Beneath the old furnaces at New Almaden 2,000 flasks were recovered by washing out the ground to a depth of 30 ft. The men and animals employed about the smelting works are subject to salivation and other injurious effects; and the same is true of mines where, as at Idria, native mercury occurs in the ores, and the atmosphere is contaminated with mercurial fumes. At New Almaden there has been little or no complaint among the miners.—Metallic mercury in its usual form has no action upon the human system; it has been taken with impunity in quantities of a pound weight; but in vapor it acts energetically, producing its constitutional effects. Poisoning occasionally results from exposure to the vapor of mercury, as from the breaking of packages in the hold of a ship, or in various processes in the arts, as in gliding, in silvering mirrors, &c. Mercury is used in medicine in many forms, all of which may give rise to its constitutional effects, varying in the time required for the production of their action and in the nature of the local disturbance they produce. Mercury with chalk, or Hymenarrhenum cum arela, prepared by rubbing up 3 oz. of mercury with 5 oz. of prepared chalk, and blue pill made from a mass composed of 1 oz. of mercury rubbed up with 1½ oz. of confection of roses, and then beaten with 4 oz. of powdered liquorice root, are
preparations in very frequent use. The metal should be contained in them in a state of division so fine that its globules are not made visible by a lens magnifying four diameters or more. A small portion of oxide is probably present in them also, which is more soluble than metallic mercury, and thus renders the preparations more active. When blue pill is taken in small but repeated doses, the first appreciable effect is usually an increased activity of the secretions, particularly of the intestinal canal, the discharges from which become liquid and bilious; the mucous membrane of the lungs and genito-urinary apparatus may display a similarly augmented secretion. If there happen to be anywhere an interstitial deposit of fibrine, or an exudation of lymph, or effusion of serum, its absorption may now be promoted; although Stille says if the mercurial influence be carried too far, extensive ulcers will appear, sometimes coated with false membranes or exudations, and the eyelids and ankles may become edematous, and even general dropsy may ensue. In the next grade of the unfavorable action of mercury the appetite fails; digestion is impaired, the secretions become still thinner and more copious, the firmness of the tissues diminishes, newly formed callus is dissolved, and recently healed wounds open afresh; the muscles waste, the skin has an earthy paleness, with the other consequences mentioned above. These symptoms, says Stille, appear to depend upon the radical change which the blood has undergone by losing a large portion of its natural solid constituents, and perhaps a formation of less highly vitalized compounds of albumen with the mercurial salt. Salivations is one of the most ordinary effects of the continued use of mercury, and consists in a copious flow of watery saliva, accompanied with swelling and soreness of the gums and a peculiar fitor of the breath. Ulcerations of the mouth may occur. The power of mercury to increase the secretion or discharge of bile, which for many years has been one of the most undoubted articles of medical faith, has recently been called in question; but although it can be shown clearly enough that in certain dogs the secretion of bile is not increased thereby, yet there seems to be not only clinical but experimental evidence to show that, in some way or other, the flow of bile into the intestine is rendered more copious by mercurial action. The constitutional action of most of the other mercurial preparations resembles that first described. Calomel (technically called hydrargyri chloratum mite) is often given as a cathartic, and when so given produces no constitutional action whatever, except in persons who are endowed with a peculiar and exceptional sensitiveness to its action. Corrosive sublimate is an irritant poison even in quite small doses, but when given in doses of \( \frac{1}{20} \) to \( \frac{1}{10} \) of a grain it is one of the best forms in which to use the drug for its systemic action. Turpeth mineral, which is a basic sulphate, is used as an emetic, and only exceptionally is absorbed in sufficient quantity to produce constitutional effects. Inunctions with mercurial ointment and fumigations with the bisulphuret or other salts may also introduce the metal into the system and give rise to the effects above described. Both calomel and corrosive sublimate have been injected subcutaneously, but when administered in this way are liable to produce abscesses. Mercurial fever and mercurial tremors, the latter often an extremely obtrusive affection, are among the constitutional effects of mercury. Stillé says: "Few medicines produce such a marked sense of depression, both mental and bodily, as mercury even in ordinary doses; but when the system is brought thoroughly under its influence, these effects become distressing; the susceptibility to external impressions, and particularly to that of cold, is augmented, pains in the limbs are felt, slight annoyances disturb the equanimity, and sometimes mental debility ensues, so that a moody melancholy and fear of death may overtake the patient." The statements in regard to the resemblance of lesions induced by mercury to those of the later stages of syphilis are probably exaggerated, as the symptoms of mercurial poisoning, however severe they may be, are not, so far as can be ascertained by examining workmen in establishments where mercury is used and mercurial poisoning familiar, the same as those of syphilis. It is impossible to give in any reasonable space an account of the uses which have been made of mercury in various diseases. It is much less used now than formerly, and its marked constitutional effects when it is employed are avoided, if possible, rather than sought for. It is most largely employed in the treatment of syphilis, but it can be shown that even here it is not absolutely essential, although surgeons of great experience are confident that the disease is rendered shorter and more curable thereby. The general verdict of the medical profession is undeniably in favor of using mercury in the treatment of syphilitic disease, but of limiting its use to appropriate cases. It should not be administered indiscriminately in syphilitic any more than in other affections. In tertiary syphilis it should be used with great caution, if at all. It is given most advantageously in the primary, secondary, and hereditary forms of the disease, when these occur in individuals whose constitutions are capable of bearing the action of the drug. Whenever inflammation, especially of serous membranes, is accompanied with exudation, the careful administration of mercury is often of advantage in promoting absorption of the exudation. Mercury is a dyad, and forms two sets of compounds, the mercurious and mercuric salts; there are two oxides, mercury monoxide or mercuric oxide, HgO, and mercurious oxide, Hg₂O. When mercuric oxide is prepared by decomposing the ni-
MERCURY.

trate by heat, it has a bright orange color, and is known as the red oxide of mercury. In the state of a finely levigated powder, or as an ointment, this is applied externally in medicine as a stimulant and caustic. The name red precipitate, or precipitate per se, was given to this oxide because of the manner in which it was formerly prepared. Mercury in a mattress (a glass vessel with a long narrow neck) was subjected continuously to the action of heat. The mercurial vapor rising in the neck of the mattress was converted into red oxide, which was prevented from escaping; and as the operation went on for weeks, the whole was converted into the same compound. Other mercurial compounds of special interest are the subchloride and chloride, the one described under CALOMEL and the other under Conso-

sive Sublimates. In the arts, mercury is em-

ployed in the construction of philosophical ins-

truments, and is preferred to other fluids for filling thermometers and barometers by reason of the great range of temperature through which it expands or contracts uniformly with equal increase or decrease of heat. Its amal-
gam with tin is largely used for coating or "silvering" the backs of mirrors. The paint, vermilion, is its sulphuret, cinnabar. But its principal consumption is in the extraction of silver and gold from their ores in the amalga-
mating process. (See AMALGAMATION.)

MERCURY, or Hermes, an ancient deity of the Greeks and Romans. According to the Greek legend, he was a son of Jupiter and Maia, a daughter of Atlas. He was born in a cave of Mt. Cyllene, in Arcadia, whence his epithet Cyllenian. Soon after his birth, escaping from his cradle, he went to Pieria, and stole several of Apollo's oxen, which he drove to Pylos, where he slaughtered two for a banquet and sacrifice, and concealed the rest. On returning to Cyllene, he found a tortoise at the entrance of his cave, of whose shell and some of a glass ox oxen he constructed the first lyre. Apollo, knowing who had stolen his cattle, went to Cyllene to demand restitution; and when Mercury denied the theft he took him before Jupiter, who obliged him to con-

fess. But when Apollo heard Mercury per-

form on the lyre, he was so delighted that he permitted the young musician to retain the cattle, and presented to him his golden caduce-

us, or pastoral staff, teaching him at the same time the art of prophesying with dice. Jupi-
ter appointed him herald general of the gods, in which capacity he was frequently the medi-

um of communication between mortals and immortals. It was he who conducted Priam to Achilles, when the venerable monarch went to beg the body of Hector from his conqueror. He bound Ixion to the wheel for boasting of intimacy with Juno, chained Prometheus to the Caucasus, and escorted Juno, Venus, and Minerva to Mt. Ida to submit their charms to the judgment of Paris. Mercury was es-

teemed the author of various inventions, and

the origin of letters, numbers, astronomy, music, military tactics, gymnastics, weights, and measures was ascribed to him. He was also regarded as the god of eloquence, the pre-
siding deity of the gymnasium, and the patron of fraud and perjury. The original seat of his worship was Arcadia, whence it gradually spread over the Grecian world. His festivals were called Hermaia. The most celebrated of his temples was that on Mt. Cyllene. The principal things sacred to him were the palm tree and the tortoise. He is generally repre-

sented as a young man with a broad-brimmed hat adorned with wings, in his right hand a herald's staff or a sceptre, and on his feet a pair of winged sandals. In Rome, Mercury was the god of commerce and diplomacy. The etyma

of his name, merx and curius, clearly indicate his predominant function. A temple was raised to him in Rome near the Circus Maximus as early as 495 B. C., and an altar of his stood contiguous to the Porta Capena. Under the cognomen of Malevorus, or the "ill-disposed," he had a statue in the eicus sobrius, or Sober street, in which no wine shops were allowed to be kept, and there milk was the solo beverage offered to him. This statue held a purse in one of its hands as a symbol of his commercial functions. The festival of Mercury was cele-

brated on the 26th of May, which was regarded as a high day by the Roman merchants. After the various relations of Greece and Rome had become intimate, the Hermes of the former and the Mercurius of the latter were popularly considered identical, though the resemblance between the two divinities was very slight, and was never admitted by the fetiales, or guardians of the public faith of Rome.

MERCURY, the planet nearest to the sun, travelling at a mean distance from it of about 35,392,000 m. The eccentricity of the orbit of Mercury is considerable, the centre of the orbit being more than 7,000,000 m. from the centre of the sun. Thus his greatest distance from the sun amounts to about 42,669,000 m., his least to about 28,115,000 m. Thus, when he is near the earth, Mercury's distance from us amounts to about 48,000,000 m.; but when so situated he is not visible, because, being between us and the sun, his darkened hemisphere is turned toward us. His greatest distance amounts to about 135,500,000 m. When he is at his greatest distance his illuminated face is turned di-
crectly toward the earth; but he cannot then be seen because he lies in the same direction as the sun, and is lost in the superior glory of that lumi-
nary. He is seen most favorably when nearly at his greatest elongation; that is, when two lines drawn to the sun and Mercury include their greatest angle. At such a time he is about 85,000,000 m. from us, and appears as a half
disk. As he is illuminated with great brilliancy on account of his nearness to the sun, he is a difficult object of telescopic study, the more so that when most favorably situated the illumin-
ated portions of his disk are seen obliquely.
Therefore very little reliance can be placed on the accounts some telescopists have given of marks supposed to be seen on the planet's surface, nor can his rotation period be regarded as fully determined from features so unsatisfactorily observed. Even the estimates of his diameter can scarcely be regarded as altogether trustworthy; but it is not probable that it greatly exceeds or falls short of 3,000 miles. His volume is about \( \frac{10}{7} \) of the earth's, and his density greater than hers in about the proportion of 10 to 9; so that his mass is about \( \frac{10}{7} \) of the earth's. He travels round the sun in rather less than three of our months, his mean sidereal revolution being completed in 87'9693 days. His mean synodical revolution, or the mean interval between his successive returns to inferior conjunction, amounts to 116'877 days; so that he passes through all his phases in the moment of inferior conjunction toward the sun's elongation west of the sun, thence to superior conjunction through maximum elongation west of the sun, to inferior conjunction again) more than three times in the course of each year. But as he is only visible for a short time after sunset on three or four evenings when his elongation is easterly, and for a short time before sunrise on three or four mornings when his elongation is westerly, he is not often seen. In America he might be seen oftener than in England, however, as the twilight skies are seldom so dense as in the latter country.

It is commonly said that Mercury rotates on its axis in 24h. 5m. 28s.; but great doubt rests on the determination of this element, for the reason above mentioned. — Mercury, travelling within the earth's orbit, sometimes transits (or passes across) the face of the sun. The first phenomenon of this sort ever observed took place in November, 1631, and was witnessed by Gassendi. A transit of Mercury is not so important in astronomy as a transit of Venus, because the nearness of Mercury to the sun prevents his having a measurable relative parallax; in other words, whereas Venus, seen from two distant stations on the earth during any moment of her transit, is projected at two spots measurably separated from each other on the sun's disk, this is not the case with Mercury.  

The observation of Mercury in transit, however, is interesting as illustrating the phenomena which occur during a transit of Venus. The formation of the "black drop," a small black ligament which at the moment of a transit connects the disk of the planet with the dark space outside the solar disk, is very manifest in the case of Mercury, though, owing to his disk being so much smaller than that of Venus, and his motions more rapid, the phenomena are not so readily studied. Transits of Mercury take place at intervals of 13, 7, 10, 3, 10, and 3 years.

**MERCY, Sisters of, or Order of Our Lady of Mercy**, a religious order founded in Dublin by Miss Catherine McAuley in 1830. Miss McAuley was born in Gormanstown castle, near Dublin, Sept. 29, 1787, and died Nov. 13, 1841. Her parents, who were Roman Catholics, died while she was a child, and she was brought up without any definite religious faith. But she became a Roman Catholic, and devoted herself and her large fortune to the service of the poor. She induced several ladies to join her, purchased a house in Dublin, and there in 1827 opened an asylum for destitute young women and a free school for poor children. Soon afterward she and her companions underwent a regular novitiate in a convent of Presentation nuns, and in 1831 assumed there the habit and took the vows of the new order. The rules first drawn up were sanctioned by the archbishop of Dublin, Jan. 23, 1834; but subsequently the rule of St. Augustine, modified to suit the active duties of the sisterhood, was adopted by them, approved by Gregory XV. in 1855, and formally confirmed by him in 1840. The sisters of mercy spread rapidly over Great Britain and her colonies. The first American house was established at St. John's, Newfoundland, in 1842, and the first in the United States at Pittsburgh in 1843. In 1874 the order possessed houses of protection for servant girls, schools, asylums, and hospitals in all the New England, middle, and western states, including California and Washington territory, and in nearly all the southern states. —The sisters of mercy have in view, besides other charities, the visitation of the sick and prisoners, the instruction of poor girls, and the protection of virtuous women in distress. Wherever their means permit they found "houses of mercy," where destitute girls of good character are cared for until employment can be found for them. They are subject to the bishops, and have no general superior, the communities of each diocese in the United States forming one body governed by a common superior, who is elected by the presscd choir sisters and confirmed by the bishop. The sisterhood is divided into two classes, choir sisters and lay sisters. The former are employed about the ordinary objects of the order, and the latter about the domestic avocations of the convent and such other duties as may be assigned to them. Candidates for membership of either class undergo a preliminary "postulancy" for six months; at the end of that time they assume the white veil and become novices. The novitiate lasts two years. The vows which are taken for life, bind the members to poverty, chastity, obedience, and the service of the poor, sick, and ignorant. The habit of the order is a black robe with long loose sleeves, a white coif, and a white or black veil. In the streets a bonnet of black raso is worn instead of the coif and veil.

**MERGANSER**, a name applied to most of the saw-billed ducks, of the subfamily merginae, of which the goosander, the largest species, has been described under that title. The bill is very slender, narrow, compressed, ending in
a conspicuous nail, with the edges serrated; tarsi much compressed, the scales largest anteriorly; and the tail feathers 18 in the North American species. In the genus *mergus* (Linn.) the bill is longer than the head, and mostly red, with the serrations conical, acute, and recurved; the tarsi about two thirds of the middle toe, tail about half the length of the wings, and head with a depressed crest. The red-breasted merganser (*M. serrator*, Linn.), sometimes called sheldrake in this country, is about 2 ft. long, with an extent of wings of 33 in., bill 2½ in., and a weight of 2½ lbs. In the male, the head and upper neck are dark green, the throat reddish brown with black streaks, sides finely barred with transverse black lines, feathers in front of wing white with black margins, white of wing crossed by two black bars, and under parts reddish white; head with conspicuous pointed crest; nostrils posterior. In the female, the upper parts are ash-colored, the lower reddish white, compressed crest chestnut brown, black at base of secondaries exposed; outer tertials white, edged with black. This bird is distributed over the whole of North America and Europe, fishing chiefly in fresh water; it breeds in the middle and eastern states, and as far north as Labrador, beginning to build, according to latitude, from the first of March to the middle of May, among the rank grasses near fresh water; the nest is carefully made of dried weeds and mosses, and lined with down from the breast of the female; the eggs are from 6 to 10, 2½ by 1½ in., in shape like those of the domestic fowl, and of a uniform pale yellowish cream color; the young take to the water at once, swimming and diving with great expertness. It is a very shy bird, and difficult to procure; the flight is rapid and well sustained; the habits are gluttonous; the food consists of fish, and its flesh is tough and fishy.—In the genus *lophodytes* (Reich.) the bill is shorter than the head, black, with oblique, low, short serrations, and the point truncated and not recurved nor acute; tail more than half the wings, tarsi half the middle toe, and head with an erect vertical crest. The only species is the hooded merganser (*L. cucullatus*, Reich.), which is about 18 in. long, with an extent of wings of 26 in., bill 2 in., and a weight of about 1½ lb. In the male, the head, neck, and back are black, with the under parts and centre of crest white; sides chestnut brown, barred with black; two black crescents on the white in front of the wing; lesser covert gray; speculum of wing white, with a basal and median black bar; tertials black, with central white streaks; crest semicircular. In the female, the crest is shorter and more pointed; the head and neck reddish brown; no pure black on the back nor bars on the sides; white on the wings less, and the size much smaller. This, with the exception of the European white merganser (*mergellus albellus*, Selby; see SMew), is the handsomest of the family. The habits are those of the other mergansers; it is distributed over the whole of North America. The eggs are like those of the preceding species, except that they are...
MERIDA

smaller; the flesh has a fishy taste and odor.—There is a small merganser in South America, for which was established the genus mergan-netta (Gould), which seems to mark the transition from the ducks to the mergansers. The bill is as long as the head, straight, compressed, elevated at the base; the shoulder of the wing in both sexes is armed with a strong sharp spur; the tail is lengthened and rounded, of rigid and pointed feathers. The only species mentioned by Gray is the M. armata (Gould), found inhabiting the rapid rivers of the Andes, swimming and diving against the mountain torrents with the utmost ease; so at home is it on the water, and so rarely disturbed, that it seldom makes use of its wings except for short flights; they are generally seen in pairs.—The affinity of the mergansers with the ducks is further shown by the occurrence of hybrids; in the cabinet of the Boston society of natural history there is a wild hybrid between the L. cedrelatus and the golden-eyed duck (Gymophila Americana).

MERIAN. I. Matthäus, the elder, a Swiss engraver, born in Basel in 1593, died in Frankfurt in 1651. He studied four years in Zürich under Dietrich Meyer, a glass painter and engraver, lived several years in Paris, and afterward in Frankfurt. He is best known by views representing the environs of Heidelberg, Stuttgart, and other cities, from his own designs (80 vols., Frankfurt, 1640—88). II. Matthäus, the younger, son of the preceding, born in Basel in 1621, died in Frankfurt in 1687. He studied painting under Vandyke, and attained a considerable reputation, especially for his portraits of the emperor Leopold I. and other German princes, painted after the manner of Vandyke. He also executed a " Martyrdom of St. Lawrence" in the cathedral of Bamberg, and other historical pictures, and was an engraver. III. Maria Sibylla, sister of the preceding, born in Frankfurt, April 12, 1647, died in Amsterdam, Jan. 19, 1717. She drew from nature flowers, caterpillars, butterflies, and similar objects, which she executed in miniature. In 1665 she was married to Johann Andreas Graeff, with whom she took up her residence in Nuremberg, retaining her own name. A work on caterpillars, illustrated from her designs, was published in Dutch (2 vols. 4to, Nuremberg, 1679—89). A Latin translation appeared in Amsterdam in 1717, and in 1780 an enlarged edition was published there in French under the title of Histoire générale des insectes de l'Europe. In 1684 she settled with her husband in Holland, and in 1688 sailed for Surinam, where during a residence of two years she prepared the materials for her Dissertatio de Generatione et Metamorphosis Insectorum Surinamensium (Amsterdam, 1705), of which a new edition was published soon after her death under the supervision of her daughters. Her two works were republished together in 1765—71 under the title of Histoire des Insectes de l'Europe et de l'Amérique (fol., Paris). Two volumes of her original drawings are preserved in the British museum.

MÉRIDA (anc. Augusta Emerita), a city of Estremadura, Spain, on the right bank of the Guadiana, in the province and 30 m. E. of the city of Badajoz; pop. about 5,000. The streets are paved and clean; the houses are mostly very ancient. The town contains a hospital, a lunatic asylum, a theatre, three churches, two nunneries, and four primary schools. Mérida is famous for its well-preserved monuments of Roman antiquity. The Guadiana is here crossed by a bridge built by Trajan, and rebuilt in 1610 by Philip III., with 81 arches, 2,575 ft. long, 26 ft. broad, and 33 ft. above the bed of the river. Another bridge, 450 ft. long, which still retains its original Roman pavement, crosses the little stream Albarréngos. There is also a triumphal arch 44 ft. high, built by Trajan; a well preserved amphitheatre; the piers of a stupendous aqueduct; a more modern Roman aqueduct of 140 arches, which still supplies the city with water; a gateway with an Arabic inscription; and a few remains of a castle.—Some historians suppose Mérida to have been founded by the Greeks; but it was certainly rebuilt and called Augusta Emerita by Publius Carisius in 25 B. C. It was taken by the Moors shortly after their landing in Spain in 711, and from then it was wrested by Alfonso the Wise in 1280. Prudentius describes it as a magnificent city in the 4th century; since its annexation by Alfonso it has gradually declined. The French invested the town in June, 1811, but were driven off by the English in April, 1812.

MÉRIDA, an inland city of Mexico, in the peninsula and capital of the state of Yucatan, and of the department of its own name, 22 m. from the gulf of Mexico, and 615 m. E. by N. of Mexico; pop. in 1871, 33,025, chiefly descendants of the Mayas and mestizos. It is situated in the midst of a level plain; the streets are very regular and spacious, and there are many modern buildings. On the principal square stand the cathedral, a majestic structure completed in 1598, the government house, the city hall, the episcopal palace, and the ancient college of San Ildefonso, now occupied by the treasury offices and the state tribunals. Besides the cathedral, there are 14 churches, a hospital with a revenue of $115,000 and an annual subvention of $2,400 from the state, a public library, a theatre, prison, house of correction, asylum, several political, mercantile, and literary periodicals, and a number of literary and commercial associations. Education is in a prosperous state, there being schools of law, medicine, and pharmacy, an instituto literario, private colleges, academies, and lyceums, and 14 primary and grammar schools. Manufactures are very flourishing, including cotton fabrics, cigars and cigarettes, rum, refined sugar, molasses, cordage, leather, soap, Panaman hats, &c. The annual value of manufactures is about $1,200,000. Hope, leather,
and bags are exported to Havana. The port of Mérida is Progreso, on the gulf of Mexico.

—Mérida was founded by Francisco de Montejio the younger, on the site of the antique Maya town Te-hoo, in 1542; and it was erected into a bishopric in 1561.

MÉRIDA. I. A S. W. state of Venezuela, bordering upon Zulia (formerly Maracaibo), Trujillo, and Barinas, and the United States of Colombia; area, about 10,000 sq. m.; pop. about 70,000, mostly Indians and mestizos. The surface is extremely uneven, being traversed in all directions by mountains belonging to the Andine chain, comprising 31 peaks exceeding 10,000 ft. in height. The highest summit is in the Sierra Nevada, 15,006 ft. Between the mountain ranges are lofty table lands and extensive valleys. There are 75 rivers, 33 of which flow to the Orinoco through the plains of Barinas; the largest is the Grita, a tributary of the Zulia, navigable for 50 m. from the junction. There are several lakes of considerable size, among them the Lagunilla, 3,000 ft. above the sea, yielding large quantities of urao or sesquisulfate of soda. Nearly all the productions of the torrid and temperate zones abound, and domestic animals are very numerous.

II. A city, capital of the state, on a beautiful plateau, 5,421 ft. above the sea, 310 m. S. W. of Caracas; pop. about 6,000. The streets are regular, and the houses generally low and solidly constructed, owing to the frequency of earthquakes. The city has a cathedral, several chapels, a convent, a seminary, a college, and several primary schools. The climate, though subject to frequent and sudden changes, is considered tolerably healthy; the mean annual temperature is 50° F. The chief occupations of the inhabitants are agriculture, cattle rearing, and the manufacture of cotton and woolen fabrics, which are preferred by reason of their cheapness to those from Europe. Woolen carpets, tastefully variegated with brilliant colored flowers from a native vegetable dye, are extensively made. Mérida is the seat of an episcopal see, and was once second in importance among the cities of Venezuela; but it has never fully recovered from the earthquake of 1812.

MERIDEN. A town and city of New Haven co., Connecticut, on the New York, New Haven, and Hartford railroad, 18 m. N. E. of New Haven; pop. in 1850, 3,559; in 1860, 7,426; in 1870, 10,495. The city is handsomely situated and well laid out, and has gas and water works and a paid fire department. There are three post offices, Meriden, South Meriden, and West Meriden. Its manufactories employ a capital of about $5,650,000, and produce goods to the value of $7,500,000. The principal productions are iron castings, rolled brass, manufactures of iron, steel, brass, bronze, and tin (including machinery and cutlery), woolens, carriages, cement pipe, and Britannia and electro-plated silver ware, the Meriden Britannia company being the largest of its kind in the world. Meriden contains the state reform school for boys, 3 national banks, 2 savings banks, 33 public schools, 3 daily and 4 weekly newspapers, and 12 churches. It was incorporated as a town in 1806, and as a city in 1867.

MERIDIAN. See Longitude.

MERIMEE, Prosper, a French author, born in Paris, Sept. 28, 1803, died in Cannes, Sept. 29, 1870. He studied law, and was received as advocate, but did not practise. In 1830 he became secretary of the count d'Argont, and successively officiated as secretary in the ministry of commerce and chief of bureau in the ministry of marine. In 1834 he succeeded M. Viett as inspector of ancient historical monuments of France, which furnished him with the materials for several valuable archaeological works. In 1844 he was elected to the French academy, as successor of Charles Dodier. In 1848 two letters published in the Revue des Deux Mondes on behalf of his friend Libri, who had been accused of purloining from public libraries, subjected him to an imprisonment of 15 days. In 1853 he was made a senator. He contributed to the romantic literature and drama of France the Théâtre de Clara Gasul, comédie espagnole (1825; new ed., 1865), a professed translation from the Spanish, and La Guila (1827), a professed collection of Ilyrian songs. He wrote a series of novels, La double méprise, Colombia, Carmen, La Jaquerie, &c., and several historical works. Among the latter are Chronique du règne de Charles IX. (1839), Histoire de Don. Pedro I., roi de Castille (Paris, 1843), and Épisode de l'histoire de Russie: les faux Démétrius (1854). His Mêlange historiques et littéraires appeared in 1855. His archaeological works are Peintures de l'église de Saint-Sauveur (1845), and researches in Corsica and in the south and west of France. Several of his works have been translated into German and English. A posthumous work, Lettres à une inconnue (2 vols., Paris, 1873; English translation edited by R. II. Stoddard, New York, 1874), comprises a series of letters of travel and gossip from 1842 to Sept. 28, 1870, the last having been written two hours before his death. He left numerous manuscripts, including an autobiography, announced in 1874 as in preparation for the press.

MERINO SHEEP. See Sheep.

MERINTHUS. See Cerinthus.

MERIONETSHIRE, a maritime county of North Wales, bordering on Cardigan bay; area, 602 sq. m.; pop. in 1871, 46,508. The surface is almost entirely rocky and mountainous, several of its summits attaining a height of nearly 3,000 ft. above the sea. The most celebrated elevation is Cadair Idris, whose summit is crowned with immense columns of crystaline basalt, similar to those forming the Giant's Causeway in Ireland. The principal rivers are the Dee, Maw, and Dovy. The largest lake is Bala, 12 m. in circumference. The principal minerals are copper, limestone, and slate. At the slate quarries of Festingoe several thousand
persons obtain constant employment. Limestone is also quarried. Oats, barley, and potatoes are the chief crops. Capital, Dolgelly.

**MERIVALE.** I. John Herman, an English author, born in Exeter, Aug. 5, 1779, died April 25, 1844. He studied at St. John's college, Cambridge, but took no degree, on account of his being a Presbyterian. He practised in the court of chancery, was commissioner in bankruptcy from 1851, and published several volumes of chancery reports, and a poem, "Orlando in Roncesvalles." A collection of his "Poems, Original and Translated," appeared in 1841. II. Herman, an English author, son of the preceding, born in Devonshire in 1806, died in London, Feb. 9, 1874. He was called to the bar in 1822, and subsequently appointed professor of political economy in Oxford university. He was made under-secretary of state for the colonies in 1848, and for India in 1859. He has published "Lectures on Civilization and Colonies" (2 vols., 1841-2; new ed., 1861), "Historical Studies" (1869), and, in conjunction with Sir II. B. Edwardes, a "Life of Sir Henry Lawrence" (London, 1873). III. Charles, an English author, brother of the preceding, born in 1808. He graduated at Cambridge in 1830, was select preacher before the university in 1838-40, Hulsean lecturer in 1861, and Boyle lecturer in 1864-5. In 1848 he became rector of Lawford, Essex, and in 1869 dean of Ely. He has published "Fall of the Roman Republic" (1855); "History of the Romans under the Empire" (7 vols., 1850-92); "The Conversion of the Roman Empire" and "The Conversion of the Northern Nations" (Boyle lectures for 1864 and 1865); and a "Translation of Homer's Iliad" into English rhymed verse (2 vols. 8vo, 1869).

**MERIWETHER.** a W. county of Georgia, bounded E. by Flint river, and drained by several creeks; area, 525 sq. m.; pop. in 1870, 13,756, of whom 7,369 were colored. The county is noted for its medicinal springs. The Warm Springs discharge 1,400 gallons a minute at a temperature of 90°. The chief productions in 1870 were 53,086 bushels of wheat, 200,880 of Indian corn, 28,776 of oats, 27,648 of sweet potatoes, 85,480 lbs. of butter, and 8,230 bales of cotton. There were 994 horses, 1,763 mules and asses, 7,058 cattle, 3,820 sheep, and 10,835 swine; 13 flour mills, and 2 lumber mills. Capital, Greenville.

**MERLE D'AUBIGNE, Jean Henri, a Swiss clergyman and historian, born at Eaux Vives, near Geneva, Aug. 16, 1794, died in Geneva, Oct. 21, 1872. He was descended from a distinguished Huguenot family which was driven out of France by the revocation of the edict of Nantes. He was educated in Geneva, and attended Neander's lectures in Berlin. In 1817 he was ordained, and for six years following was pastor of the French Calvinist church in Hamburg. In 1823 he removed to Brussels, where for seven years he was pastor of a Protestant congregation, and court preacher to the king of the Netherlands during his stays in that city. After the revolution of 1830 he returned to Geneva and took the chair of ecclesiastical history, and the general direction of a new theological institution founded by the evangelical society of that city. Some years later he began his principal work, Histoire de la réformation au XVIIe siècle (5 vols., Paris, 1835-53). More than 200,000 copies of the English translation of this work have been sold in Great Britain, and at least twice that number in the United States. His supplementary Histoire de la réformation au temps de Calvin (5 vols., Paris, 1862-8) was to have extended to seven volumes, but was not completed at his death. He also published Le protecteur, ou la république d'Angleterre aux jours de Cromwell (Paris, 1848); "Germany, England, and Scotland, or Recollections of a Swiss Minister" (London, 1848); Trois siecles de luttes en Ecosse, ou deux royaumes (1850); and several discourses, and papers in the Archives du Christianisme, most of which have been translated into English. In 1870 he published a pamphlet entitled Le concile et l'infalibilite.**

**MERLIN,** a European falcon, of the genus *hypotriorchis* (Boie), which differs from the genus *falco* (Linn.) chiefly in the more lengthened and slender tarsi, and long slender toes. This bird (*H. asalon*, Gmel.) is about a foot long, with an extent of wings of 29 in., the male being a little smaller; it is the smallest of the British falcons, of pleasing colors, compact and graceful in form, with large head and short strong bill, the closed wings about 1½ in. shorter than the tail. In the male, the upper parts are deep grayish blue, each feather with a black central line, the tail barred with black, and the lower parts light reddish yellow with oblong blackish brown spots; in the female, the upper parts are grayish brown with darker shafts, the tail barred with pale reddish, and the lower parts yellowish white with large longitudinal

Merlin (*Hypotriorchis asalon*).
markings; in both sexes the bill is pale blue at the base, and bluish black toward the end. From its courage and docility it was formerly trained to pursue larks and the smaller game birds. It is found all over Europe and western Asia; it very much resembles the American pigeon hawk (H. columbarius, Boie).

MERLIN, the name of two legendary British seers and sorcerers, who lived in the 6th and 7th centuries A.D. 1. Merlin Ambrosius, a native of Wales, is represented to have been the son of a demon by a Cambrian princess. When a mere youth he recommended himself to the notice of King Vortigern by the display of supernatural powers; and he subsequently became the counsellor of that monarch, and of his successors Ambrosius, Uterpendragon, and Arthur. This is the Merlin to whom allusion is made by Spenser in his "Faerie Queene," and by other old poets. He is also the subject of the metrical romance entitled "Merlin," of which Mr. Ellis has given an analysis in his "Early English Romances;" and he is prominent in Bulwer-Lytton's "King Arthur," and in Tennyson's "Idyl of the King," especially in "Vivien." A book of prophecies attributed to him was printed in French in 1498, in English in 1529, and in Latin in 1554. The principal account of him is given by Geoffrey of Monmouth in his Historia Brittonum. "The Life of Merlin Ambrosius," by T. Heywood, appeared in London in 1641. The early English text society has reprinted the first part of the prose romance of Merlin from the unique manuscript in the Cambridge university library, edited by J. B. Wheatley (1875). 2. Merlin Caledonius Sylvestris, or the Wild, a native of Strathclyde, in S. W. Scotland, was contemporary with St. Kentigern, bishop of Glasgow, in the latter part of the 6th century. According to Fordun, having slain his nephew, he fled to the woods, and there led the life of a savage till his death. A band of peasants pursuing him, he sprang from a rock into the Tweed, in order to escape the band, and was impaled on a stake that chanced to be in the bed of the river. A metrical life of him, incorrectly ascribed to Geoffrey of Monmouth, was printed for the Roxburghe club (London, 1830). The works attributed to him were published at Edinburgh in 1615; but as the rhapsodies and prophecies of the Cambrian and Caledonian Merlins are confounded, being sometimes ascribed to one and sometimes to the other, it is almost impossible to distinguish between them.

MÉRODE, François Xavier Marie Frédéric Ghislain de, a Roman Catholic archbishop, born in Brussels in March, 1820, died in Rome, July 24, 1874. His family claims descent from Raymond Berenger V., count of Barcelona and king of Aragon (died 1162); and one of his cousins was mother to Queen Maria, wife of Amadeus, late king of Spain. His mother was a niece of Lafayette; and his father, Count Félix de Mérode, took a leading part in the Belgian revolution of 1830, was a member of the provisional government, and, after refusing to be the candidate of the Catholic party for the throne, was mainly instrumental in securing the election of Leopold of Saxe-Coburg. Xavier entered the Belgian army in 1841, and served with distinction as a volunteer in Algeria under Marshal Bugeaud. He

with the garb of a bishop. The most formidable animal of this kind is the devil-merman, monstrum marinum damoniforme, captured on the shore of Illyria, seen alive at Antwerp, and described by Aldrovandus. The merrows of Irish legend are mermaids. Capt. Whitbourne minutely describes a mermaid seen by him in 1616 in the harbor of St. John’s, Newfoundland. Monsters of similar appearance have since been occasionally described.

MERODACH, or Bel Merodach, the second of the minor Babylonian gods, nearly corresponding with the classic Jupiter, and astronomically identified with the planet Jupiter. The name Merodach was at first a mere epithet of the god Bel or Belus, and by degrees superseded the proper name. Its signification or origin is unknown. The golden image in the great temple at Babylon was worshipped as Bel rather than Merodach, but other images probably represented him as Merodach, and the temple itself, described by Herodotus as the temple of Belus, is the temple of Merodach in the inscriptions. In what the distinction between the names consists, however, is not known. Bel Merodach is represented as the son of Ao and Davke, and the husband of Zibanit. He is the ancient one of the gods, and the judge, and has the gates (probably with the seats of justice near them) under his special charge. He was the tutelar god of Babylon from an early period, and the Babylonian kings were often named after him, as Merodach-baladan and Evil-merodach, such use of the name occurring as early as 1650 B. C. His worship was adopted in Assyria at a later time, probably because of the consolidation of the two monarchies about the time of Pul, who claimed to have first put Merodach at the head of the Assyrian pantheon. Merodach was most honored under the later Babylonian kings, and praises and prayers addressed to him occupy the inscriptions of Nebuchadnezzar. At first he shared with several other deities the worship of the people, but later concentrated in himself the greater part of the homage formerly given to many gods, and was regarded as the source of all power and blessings.

MÉRODE, François Xavier Marie Frédéric Ghislain de, a Roman Catholic archbishop, born in Brussels in March, 1820, died in Rome, July 24, 1874. His family claims descent from Raymond Berenger V., count of Barcelona and king of Aragon (died 1162); and one of his cousins was mother to Queen Maria, wife of Amadeus, late king of Spain. His mother was a niece of Lafayette; and his father, Count Félix de Mérode, took a leading part in the Belgian revolution of 1830, was a member of the provisional government, and, after refusing to be the candidate of the Catholic party for the throne, was mainly instrumental in securing the election of Leopold of Saxe-Coburg. Xavier entered the Belgian army in 1841, and served with distinction as a volunteer in Algeria under Marshal Bugeaud. He
went to Rome in 1848, studied theology, and was ordained priest in 1850. He was immediately appointed chamberlain to the pope and canon of St. Peter's, and was rapidly promoted, till in the beginning of 1860 he was made "pro-minister of arms." He organized the pontifical army, composed mostly of foreigners, and induced Gen. Lanoricèrie to take the command of it in April. That general having been defeated at Castelfidardo in the following September, Meroède asked the French troops in Rome to defend the pontifical authority. He soon quarrelled with the French commander, Gen. Goyon, who refused to communicate with him. In 1868 he resigned his office in consequence of a disagreement with Cardinal Antonelli. He was appointed archbishop of Melitene June 22, 1866, and private almoner to the pope. It is said that the influence of his brother-in-law, Count de Montalembert, caused him in 1869 to oppose the definition of the papal infallibility; but he accepted in 1870 the decision of the Vatican council. He devoted a large portion of his patrimonial wealth to improve the streets and squares of Rome, and to archaeological excavations; but a far larger portion was employed in founding charitable institutions and agricultural and industrial schools. His last public act was to welcome to Rome the American pilgrims from New York.

MEROÉ, a state, with a capital of the same name, forming part of the ancient kingdom of Ethiopia. It is hardly possible to fix the site of the ancient city, much less to define the boundaries of the state at any given period. The whole of Ethiopia was once called Meroé. Greek writers applied the name to an island and a city on the upper Nile. The district is in reality a peninsula, formed by the Nile and its affluents, the Arbara and Bahar-el-Azrek, between 13° and 18° N., and included in modern times in Nubia. At certain seasons it becomes an island by the overflowing of the rivers. Its length from N. W. to S. E. is about 375 m., and its breadth about 200; and it consists of extensive plains, which formerly were fertile and well cultivated, but are now for the most part desert. This country was very famous in antiquity. It produced gold, iron, copper, and salt; and partly from its natural riches, and partly from its situation between southern Ethiopia and the Red sea, it was from the earliest times the seat of a great commerce, carried on by caravans from all parts of northern Africa, which made its chief city their central rendezvous. According to Herodotus, the "great city called Meroë, which is said to be the capital of the other Ethiopians," was more than 40 days by land and 12 days by boat (22 days in all) beyond Syene. Later writers called it Merowe, king of the Napatan. During the reigns of the Osoratas and Amenhathes, about 3000 B. C., Egyptian rule extended over Nubia as far as Semneh and Kumneb, under Amenophis III., as far as Soloëb, and under Rameses II. to Mt. Barkal. The oldest ruins found here formed part of a temple to Ammon, built by Rameses II.; next in age are the ruins of Taharka's edifices. These, as well as later monuments, especially the 20 or 30 small pyramids, are imitations of Egyptian art. The monuments of Begerawieh have the same style, though somewhat mixed with foreign elements. It has long been customary to trace the culture of Egypt to that of Ethiopia and Meroë; but Egypt is a well favored land, while Meroë is excessively hot, and fertile only in oases; and the lower valley of the Nile has always been superior in culture and power to the upper; all of which renders improbable that the civilization of Egypt was in any sense borrowed from Meroë. The reverse is much more probable. There are indications in Herodotus and Diodorus that Meroë had been under the rule of priests, but in the time of Ptolemy II. King Ergamenes established an independent kingdom. The name Meroë is given in the inscriptions of Begerawieh as Mero and Mera, which Lepsius and other Egyptologists translate "white rock." Here, as well as near Mt. Barkal, the shores of the Nile are lined with cliffs of white chalk, which probably gave the name to the country. The Assyrian inscriptions of King Sargon mention the king of Meroë (Milukhi), and one of Semnachoros called it "the king of Egypt had called for the archers, chariots, and horses of the king of Milukhi." The inscriptions of Esrhadion speak of "the king of Egypt and Milukhi," whom they call also "the king of Egypt and Cush;" and Assur-bani-pal records his campaign against "Tarku (Taharka) of Egypt and Milukhi." Though the majority of Assyriologists translate Milukhi by Meroë, as George Smith in his "History of Assur-bani-pal translated from the Cuneiform Inscriptions" (London, 1874), Lenormant has come to the conclusion that Assur-bani-pal's Milukhi lay N. of Memphis, and that it was the name of a small independent kingdom which had been established in and near the western portion of the Delta. Ménant, in his Annales des rois d'Assyrie (Paris, 1874), has adopted Lenormant's opinion. (See Ethiopia.)

MEROPI. See Cos.

MEROVINGIANS, the name of the first Frankish dynasty in Gaul or France. It was so called from Meroveus, king of the Ripuarian Franks (448-56), who aided in the defeat of Attila in 451. He was succeeded by Childebric I. (458-81), whose son Clovis, the conqueror of Gaul, and the first Christian monarch of the
Franks, left his possessions in 511 to his sons Thierry or Theodoric, Clodomir, Childebert, and Clotaire, the first receiving the east (Austrasia), the second the southwest (with Orleans), the third the centre (with Paris), and the fourth the north (with Soissons). The line of Thierry became extinct with his grandson Theodebald or Thibault, son of Theodebert. The sons of Clodomir were murdered by their uncles, and Childebert left no male issue. Thus Clotaire, the youngest son of Clovis, reunited the empire of the Franks (558–61). On his death it was again divided by his four sons, Charibert reigning in Paris, Gontran or Guntram in Orleans (to which Burgundy, a new conquest, was attached), Siegbert in Austrasia, and Chilpéric in Soissons. This period was distracted by intermedie wars, during which the two princesses Brunehaut and Fredegonda, the wives of Siegbert and Chilpéric, were the most conspicuous characters. Siegbert was assassinated, and his son Childebert, who also inherited the possessions of Gontran, was succeeded by two sons, Theodebert and Thierry II, who died without legitimate male issue. Clotaire II, the son of Chilpéric and Fredegonda, reunited the whole kingdom. It was again temporarily divided by his sons Dagobert and Charibert, the former of whom was the founder of a line of kings known as fainéants (lazy), their mayors of the palace being the real rulers of France. They were as follows: Siegbert II., of Austrasia, 638–56; Clovis II., of Neustria (the western kingdom) and Burgundy, 658–56; Clotaire III., sole king, 656–of Neustria and Burgundy, 660–70; Childeric II., of Austrasia, 660–70—sole king 670–73; Thierry III., of Neustria and Burgundy (deposed in 670 and restored), 673–91; Dagobert II., of Austrasia, 674–9; Clovis III., of Neustria and Burgundy (like all the succeeding), 691–5; Childeric III., 685–711; Dagobert III., 711–15; Chilpéric II., 715–29; Thierry IV., 720–37; Childeric III., 742–52—deposed by Pepin the Short, founder of the Carolingian dynasty.

MERRICK, an E. central county of Nebraska, bounded S. E. by the Platte river, and intersected by Prairio creek and Loup fork; area, about 650 sq. m.; pop. in 1870, 557. The Union Pacific railroad passes along the S. E. border. The soil is fertile, and timber grows along the streams. The chief productions in 1870 were 9,999 bushels of wheat, 13,024 of Indian corn, 91,579 of oats, 3,035 of barley, 5,029 of potatoes, 13,205 lbs. of butter, and 1,548 tons of hay. There were 118 horses, 288 milk cows, 444 other cattle, 478 sheep, and 308 swine. Capital, Lone Tree.

MERRICK, James, an English poet, born in Reading, June 8, 1720, died there, Jan. 5, 1769. He was educated at Trinity college, Oxford, of which he became fellow in 1744. When 14 years old he published "The Messiah, a Divine Essay." He took orders, but from delicate health was unable to perform clerical duties. Among his works are: a "Translation of Tryphiodorus" (Oxford, 1741); "Poems on Sacred Subjects" (Oxford, 1763); "The Psalms Translated or Paraphrased in English Verse" (Reading, 1760); and "Annotations on the Psalms" (Reading, 1765). His "Chameleon," is the best known of his works.

MERRIMAC, a river of New England, formed by the junction of the Penigewasset and Winnepisegge rivers at Franklin, N. H. From this point the river runs S. 78 m. to Chelmsford, Mass., and thence E. 85 m. to the Atlantic ocean at Newburyport. Its tributaries in New Hampshire are the Contoocook, Suncook, Picissetaquog, Souhegan, and Nashua; in Massachusetts, the Concord, Spiggot, Shawsheen, and Powow. The principal tributaries are on the right side of the river. There are numerous falls in the Merrimack, and the river furnishes an immense water power. The employment of which in manufacturing has created the cities of Lowell and Lawrence, Mass., and Nashua and Manchester, N. H. Its width varies from 50 to 150 yards. It is navigable to Haverhill, Mass., 18 m. from the sea. The name is of Indian origin, and is derived from a word signifying a sturgeon.

MERRIMACK, a S. central county of New Hampshire, intersected by the Merrimack river, and its affluent the Contoocook, Suncook, Suncook, &c.; area, about 700 sq. m.; pop. in 1870, 42,151. The surface is broken and in many parts hilly; Mt. Kearsarge is in the N. W. portion. It is traversed by the Concord, the Suncook Valley, the Boston, Concord, and Montreal, the Concord and Claremont, the Contoocook River, and the Northern railroads, and the Bristol branch. The chief productions in 1870 were 31,404 bushels of wheat, 189,788 of Indian corn, 103,525 of oats, 472,131 of potatoes, 144,673 lbs. of wool, 745,386 of butter, 191,298 of cheese, 102,881 of maple sugar, and 78,278 tons of hay. There were on farms 4,987 horses, 10,459 milk cows, 17,696 oxen, 16,127 other cattle, 34,479 sheep, and 3,991 swine. The number of manufacturing establishments in 1870 was 414; capital invested, $4,896,995; value of products, $7,627,676. The most important were 7 cotton mills, 10 woolen mills, 8 paper mills, 36 saw mills, 6 flour mills, 12 tanneries, 11 currying establishments, 3 manufactories of agricultural implements, 3 of leather belting and hose, 2 of boots and shoes, 17 of bricks, 20 of carriages and wagons, 16 of clothing, 6 of furniture, 4 of hardware, 3 of iron castings, 6 of machinery, 4 of organs, 10 of saddlery and harness, 4 of sash, doors, and blinds, 1 of silverware, and 5 of wooden ware. Capital, Concord, which is also the capital of the state.

MERRITT, Timothy, an American clergyman, born in Barhamstead, Conn., in October, 1775; died in Lynn, Mass., May 2, 1845. He became a minister of the Methodist Episcopal church in 1796, and spent 34 years as a pastor in Boston, Lynn, Providence, Springfield, New
Bedford, and elsewhere. In 1851 he edited "Zion's Herald" in Boston, and from 1832 to 1837 the "Christian Advocate and Journal" in New York. He also started a monthly periodical in Boston entitled "Guide to Christians.

The name of the city of Khiva, and 12 m. E. of the Murghab river; pop. about 3,000. It was one of the four imperial cities of Khurasan, and was the capital of many of the Persian sultans, especially of the Seljuk dynasty. It is on the caravan road from Meshed to Khiva and Bokhara, and though in a very unhealthy country was once a flourishing town, surrounded by beautiful gardens, whose fruits had a high reputation. It was sacked by the Uzbeks about the beginning of the present century, and since then has steadily declined.

MÉRÉV, a town of Turkistan, in the khanate and 300 m. S. E. of the city of Khiva, and 12 m. E. of the Murghab river; pop. about 3,000. It was one of the four imperial cities of Khurasan, and was the capital of many of the Persian sultans, especially of the Seljuk dynasty. It is on the caravan road from Meshed to Khiva and Bokhara, and though in a very unhealthy country was once a flourishing town, surrounded by beautiful gardens, whose fruits had a high reputation. It was sacked by the Uzbeks about the beginning of the present century, and since then has steadily declined.

MÉRÉY, Joseph, a French author, born at Les Algadales, near Marseilles, Jan. 21, 1798, died in Paris, June 17, 1866. He was dismissed from a seminary for reading Voltaire, and from a law school on account of a duel. Subsequently he lived in Ireland, then in Paris, and went to Italy, whence he was soon driven by his dissipations. In 1821 he was arrested at Marseilles for writing against the abbé Elicagray, and rearrested on account of another obnoxious publication. In 1822 he visited Constantinople, quarrelled with the French ambassador, and was obliged to leave. After editing a journal at Marseilles, he established himself in Paris in 1824, and became known in conjunction with Barthélémy (see BARTHÉLÉMY, AUGUSTE MARSEILLE) by effective satires in verse against various administrations and by his adulation of the Bonaparte family, Napoléon en Égypte (1828) being one of their finest lyrics. He acquired still more literary fame by entertaining and eccentric novels and books of travel. Among the best known are Nuits de Londres (reprinted as Nuits anglaises), Itaca, La Floride, La guerre du Nizam, Les confessions de Marion Delorme, Nuits italiennes, Nuits d'Orient, Nuits espagnoles, Nuits parisianes, and Un carnaval de Paris. He wrote the libretto for Sévérinias and other operas, but was less successful in plays, of which he published a collection entitled Théâtre de salon (1861). A new edition of his Poésies intimes appeared in 1864. Some of his novels have been translated into English.

MESCALA, a river of Mexico, rises near the city of Puebla, and flows westwardly 400 m. to the Pacific, forming the boundary between the states of Guerrero and Michoacán. In Puebla it is known successively as the Atoyac and the Río Pablano, further on also as the Río de las Balsas, and at its mouth it is called the Zacatal. It was long regarded as a probable route of interoceanic communication, but it is not navigable on account of frequent rapids. The waters of the Mescal are supposed to contain deleterious elements, which have caused a loathsome disease of the skin, prevalent among the Pinto (i.e., spotted) Indians living on its banks. Rich gold placers are found in its mouth.

MESEMBRYANTHEMUM (Gr. meision, mid-day, and avdos, a flower), a genus of succulent
plants called fig marigolds, and by the French,

*récoids*, as some species produce an edible fruit resembling a fig. The genus is large, consisting of about 300 species, and the principal one in a small family, the *frécioiidae* or *mesembryanthemaceae*. Some of the species are annual, others perennial, with half shrubby, branching stems, and in others the stem is very short, the leaves being collected in a compact rosette like a houseleek. They are natives of warm, dry countries, the greater number being from southern Africa; the leaves in all are exceedingly succulent and well adapted to resist the long droughts of their native regions. Perhaps half of the whole number are in cultivation; the flowers are generally showy, and consist of four or five sepals united by the base and adhering to the ovary, and numerous, very narrow petals, which are often in several series and give the flowers much the appearance of a head of some composite plant; they are white or of different shades of yellow and rose color. The capsule has at the top a series of slits arranged in a star-like manner; these slits remain closed while the capsule is dry, but when the rains have rendered the soil suitable for the germination of the seeds, the slits open by the action of the moisture and allow them to escape. The best known annual species, *M. crystallinum*, is described under Ice Plant. The perennials are cultivated as greenhouse plants, and are occasionally used for bedding out in summer. The flowers open only on bright days, and usually at noon, but the plants are cultivated quite as much for their striking and odd foliage as for their flowers.

The diversity of forms presented by the different species of this genus is remarkable. *M. dolabriforme* is so named from the resemblance of the leaves to the ancient axe or hatchet; in *M. deltoides* a cross section of the leaf presents the outline of the Greek Δ; both of these are tall and branching. *M. tigrinum* is one of the low compact species in which the leaves are fringed with strong, spiny teeth, suggestive of a tiger's jaw. The plants are of the easiest cultivation and require but little water. For so large a genus it contains but few useful species. *M. edule*, the Hottentot's fig, has an edible fruit resembling a small fig, while the leaves of some species and the seeds of others serve as food.

**MESHED**, or **Meshid**, a city of Persia, capital of the province of Khorasan, in an extensive valley of the same name, about 185 m. N. W. of Herat, 300 m. E. of the southern extremity of the Caspian sea, and 480 m. E. of Teheran; lat. 36° 30' N., lon. 59° 35' E.; pop. estimated at 70,000. It is surrounded by walls 12 m. in circuit, enclosing much space occupied only by extensive burying grounds, and great tracts of ruins, the population being mostly confined to the centre. Its principal street is spacious and handsome. The place is chiefly known by the splendid mausoleums of Imam Riza, Haroun al-Raschid, and Nadir Shah. Next to Mecca, it is the most sacred place for a Shah Mussulman, and many pilgrims visit yearly the shrine of Imam Riza, which is crowned with a splendid copper and alabaster minaret, and stands in a court 480 ft. long and 225 ft. broad. The court is incursted with mosaic work of painted and glazed tiles, and entered by four lofty gateways. The shrine is entered through a silver gate, the gift of Nadir Shah. Within the same court is the mosque of Gohur Shah, which is also very splendid. Meshed contains several colleges, a spacious but unfinished caravansary, and a palace which is also a citadel. There is an aqueduct whose banks are shaded with trees. Velvets esteemed the best in Persia, sword blades of celebrated temper, some kinds of armor, and some silk and cotton goods are manufactured; and many of the inhabitants are employed in cutting gems from the turquoise mines in the vicinity. There is an important commerce, by the great caravan routes of Persia, with Bokhara, Khiva, Herat, Kerman, Yazd, and other quarters; rich caravans arrive daily. Near by are the ruins of Thus, the home of the poet Firdusi. The town suffered terribly from the famine of 1871.
MESILLA, a town of Doña Ana co., New Mexico, on the right bank of the Rio Grande, about 240 m. S. by W. of Santa Fé; pop. in 1870, 1,578. The town is situated in a valley of the same name, obtained notoriety from a dispute between the United States and Mexico in the settlement of the boundary under the treaty of Guadalupe Hidalgo, made in 1848. It was subsequently included in the purchase by the United States under the "Gadsden treaty" of 1853. Mesilla is the diminutive of the Spanish mesas, table; as here applied, it means a small plateau, or table land, on the bottom land of the Rio Grande, to distinguish it from the great table land, which is more elevated, and which extends for many hundred miles on both sides of the river. The Mesilla valley is about 80 m. long and from 1 to 4 m. wide. The soil is a rich alluvium, but artificial irrigation is required.

MESMER, Friedrich Anton, a German physician, the first promoter of animal magnetism, or "mesmerism," born at or near Meersen, Baden, on the lake of Constance, in 1734 or 1794, died there, March 5, 1815. He studied medicine in Vienna, and took his degree of M. D. there in 1766, presenting on that occasion a thesis De Planetarum Influenz in Corpus Humano, in which he held that the universe is pervaded by a subtle element exercising an extraordinary influence on the human body, and identical with the magnetic element. The means by which he brought his theory into notice, and the leading features of his life, are given under the head of Animal Magnetism.

MESOLONGHI. See Messolonghi.

MESOPOTAMIA (Gr. μεσός and ποταμός, between the rivers, viz., Euphrates and Tigris; Heb. Aram Naharaim, Aram or Syria between the two rivers; now Al-Jezireh, the island), an ancient country of western Asia, bounded, according to the common acceptance of the name, N. by Armenia, from which it was separated by the Masius range, a branch of the Taurus; N. E. and E. by the Tigris, separating it from Assyria; S. by Babylonia; and S. W. and W. by the Euphrates, separating it from Syria. The Greek name seems to have been first used in the time of the Seleucids. Mesopotamia has never been a political designation, but always a purely geographical one; and it is sometimes found applied also to the regions bordering on the valley of the two rivers. Excepting the Masius range and its prolongation parallel to the upper Tigris, Mesopotamia formed a vast and mostly very fertile plain, well watered by rivers and canals, the chief stream between the two great rivers being the Chaboras, an affluent of the Euphrates, and the principal productions of the country include fruits, spices, timber, cattle, naphtha, and jet. The southemmost part of the plain, however, resembled the adjoining regions of the Syro-Arabian desert, and was inhabited by numerous wild animals, including lions, ostriches, and wild asses. Among the cities of Mesopotamia were: Apamea on the Euphrates, opposite Zeugma in Syria; Edessa (now Urfa), the capital of the province of Osrhoene; Carré or Carrhae, the Haram of Abraham's Chaldea, the Scriptural Carchemish, near the mouth of the Chaboras; and Nisibis (Nizib), the Scriptural Zoba, in the province of Mygdonia. Mesopotamia was inhabited by a people called Rotemnu or Retennu on the Egyptian monuments. They were of Semitic race, and were struggling with Egypt for supremacy as early as 1600 B. C. In later times it was in turns a part of the Assyrians, Babylonia, Persian, Macedonian, Syrian, Parthian, and Neo-Persian monarchies, until it was conquered by the Arabs. It was subsequently invaded by the Seljuk Turks, conquered in part by the crusaders, and finally became a province of the Ottoman empire.

MESSALA, or Messalia (Marcus Valerius Messala Corvinus), a Roman general, born according to Eusebius in 59, but according to Scaliger about 70 B. C., died about the beginning of the Christian era. He completed his studies at Athens, and on the outbreak of the second civil war joined Brutus and Cassius in the East, was appointed to the third rank in the republican army, and commanded under Cassius at Philippi (42). After the overthrow of his party he surrendered to Antony, to whom he attached himself until, perceiving the ruin of that triumvirate inevitable, he withdrew from his service, and entered that of his rival, for whom he fought in Sicily, against the Salassi in the Alps, and at Actium (31). He was appointed to succeed Antony as consul, and subsequently he obtained the proconsulship of Aquitania, for the reduction of which province a triumph was decreed him. He was selected by the senate to greet Octavius with the title of pater patriae, and the exordium of his oration has been preserved by Suetonius. Soon after this Messala resigned all his official dignities except the augurship, and retired to private life. Fragments of his orations remain (Paris, 1842); his other writings are only known by their titles.

MESSALINA, or Messalina, the name of two Roman empresses, who lived in the 1st century of the Christian era: 1. Valeria, daughter of M. Valerius Messala Barbatus, and third wife of Claudius, to whom she was married before his accession to the empire. She was equally profligate and cruel. Many members of the most illustrious families of Rome were sacrificed to her fears, her jealousy, or her hatred. Among her noblest victims were the two Julias, one the daughter of Germanicus, the other of Drusus, son of Tiberius, who had excited her jealousy or envy; C. Appius Silanus, who had wounded her vanity by rejecting her advances; and Justus Catonius, whose offence was privity to her guilt. For a long time Claudius was blind to her infidelity; but when, during his absence at Ostia, she contracted a public marriage with Caious Silius, a handsome youth for whom she had conceived a violent passion, he
caused her to be put to death. The sentence was executed in A. D. 48, by a praetorian tribune, in the gardens of Lucullus. By Claudius she was the mother of two children, Britanius and Octavia. **II. Statilla**, the third wife of the emperor Nero, whom she survived, and the granddaughter of T. Statilius Taurus, who had been consul in A. D. 11. She was first married to Atticus Vestinus, but the tyrant caused her husband to be put to death, and espoused her in 66.

**MESSANA.** See Messina.

**MESSAPIA**, the ancient Greek name of the peninsula forming the S. E. extremity of Italy, called by the Romans Calabria, a name applied in modern times to the opposite peninsula. (See Calabria.) The boundary separating it from Apulia on the N. W. was not well defined, but Messapia consisted of what is popularly called the "heel of the boot." The peninsula was probably first known to the Greeks by the name of Japygia, which was afterward applied by them to all S. E. Italy. Herodotus speaking of Apulia as a part of Japygia, while Messapia indicated the peninsula only. Later writers make Japygia and Messapia synonymous, and confine them to the peninsula. The inhabitants were of two tribes, the Salentini along the S. W. coast near Tarentum, and the Calabri, whom the Greeks called Messapians, on the N. E. part. The latter were the more powerful, and the whole district came to be called after them by their Greek and Latin names respectively. It terminated at the S. E. in the rocky Japygian promontory (now Cape Loeuca), standing boldly out into the sea. It was celebrated for its fertility, abounding in wine, olives, and other fruits. (See Otranto, Tana d'.) The Calabrian heros were famous, and the Tarentine cavalry was long celebrated. Virgil says that the region was infested by particularly venomous serpents. The inhabitants were of Pelasgic origin, had attained a considerable culture, and possessed the cities of Hyria or Uria and Brundusium in the latter part of the 8th century B. C., when the Greek colony of Tarentum was founded. They fought against the Greek colonists for many years, defeating the Tarentines in a great battle about 473, but were gradually overcome by the Greek civilization and corrupted by its luxury. They made a short resistance to the Romans, uniting with neighboring tribes under the command of Pyrrhus, but were overcome in a single campaign after his fall. They revolted to Hannibal in the second Punic war, but were soon subdued. Under the empire Messapia was united for administrative purposes with the province of Apulia. The Byzantine emperors retained a footing here during the invasion by the Goths and Lombards, and were not finally expelled till the 11th century.

**MESSENE**, the capital of Messenia in the Peloponnesus, founded by Epaminondas after his victory of Leuctra over the Lacedaemonians, 371 B. C. It was at the foot of the hill of Ithome, the fortress of which formed the acropolis of the new capital, and was surrounded by massive stone walls, flanked with towers, of which there are still considerable remains at the modern village of Mavromati. Messene with its acropolis was, next to Corinth, the strongest city of the Peloponnesus. It was supplied with water from a fountain called Cleopatra, the spring of which still exists.

**MESSENIA, or Messene**, the S. W. division of the Peloponnesus in ancient Greece, bounded N. by Elis, from which it was separated by the river Neda, and Arcadia; E. by Laconia, the boundary line varying at various periods; S. and W. by the sea, which on the south forms the large gulf of Messenia, or, as it is now sometimes called, of Corinon. It is a mountainous country, containing but two plains of any extent, the southern of which, traversed by the Pamisus, was called Macaria or the Blessed, on account of its great fertility. The valleys among the mountains were also fertile, and the whole country was renowned for the mildness of its climate. Among the few towns of note were Pylos, a seaport. Cyparissia, Corone (now Coronon), Methone (Modon), Abis, Dera, Stemylarion in the northern plain of the same name, and the later capital Messene, besides the mountain fortresses of Ithome and Ira. The earliest inhabitants of Messenia were Leleges and Argives. Polyaen, son of Lelex, is said to have given the country its name from Messene, his wife, daughter of the Argive Triopas. It was subsequently settled by Eolians. During the following period Messenia seems to have belonged partly to Pylos and partly to Lacedaemon. When the Dorians conquered the Peloponnesus, it became the possession of Cresphontes, who destroyed the kingdom of Pylos. Of this and many statements, the eastern neighbor, soon developed its aggressive policy, and after various collisions and mutual invasions the first Messenian war broke out. It is said to have lasted 20 years, its principal Messenian hero and victim being Aristodemus, and ended with the fall of Ithome and the subjugation of Messenia. After 38 years of subjection, the Messenians rose under the lead of Aristomenes, supported by Argos, Arcadia, and other states of the Peloponnesus, while their enemies received the support of Corinth. Aristomenes succumbed after a struggle of 17 years, and Ira fell. (See, Argos, Messen, and Tyrhec.) In common chronology the first war is placed at 743–723 B. C., and the second at 685–668. The two great struggles are considered as sufficiently attested, but the particulars, which are highly poetical and rest on authorities of the 5th century B. C., are justly doubted. The consequence of the wars was the emigration of a large number of the inhabitants to Italy and Sicily, giving the names of Messene or Messana to the town of Zancle in that island, and the subjection of those who remained to the condition of helots. Together with the other slaves of Sparta, they
were induced by the great earthquake which devastated the capital of their oppressors in 464 to strike once more for freedom. This third Messenian war lasted ten years, and was terminated by the capitulation of the defenders of Ithome, who were allowed a free departure from the Peloponnesus. They settled at Nau- pactos, on the northern shore of the Corinthian gulf, a town recently conquered by Athens, now the declared rival of Sparta. When the former was crushed by the fatal issue of the Peloponnesian war, the Messenians of Nau- pactus were compelled to leave Greece. Epaminondas finally restored the independence of Messenia, convoking the refugees from the various lands of their exile, after the great battle of Leuctra (371), and giving the country a strongly fortified capital in Messene, a new town at the foot of the old stronghold Ithome (369), which was maintained down to the time of the Roman conquest of Greece in 146. — The modern nomarchy of Messenia is bounded N., by Achala and Ælis, E. by Arcadia, S. by the gulf of Messenia or Coron, and W. by the Ionian sea; area, 1,226 sq. m.; pop. in 1871, 130,417. Capital, Kalamata.

MESSER, Asa, an American clergyman, born in Methuen, Mass., in 1769, died in Providence, R. I., Oct. 11, 1836. He graduated at Brown university, where he became in 1796 professor of languages, in 1799 professor of mathematics and natural philosophy, and from 1802 to 1827 he was president of the university. He was licensed to preach by the first Baptist church in Providence in 1792, and ordained in 1801. The citizens of Providence for several years elected him to important civil offices. Three of his discourses and five orations have been published.

MESSIAH. See JESUS CHRIST.

MESSINA. I. A province of Sicily, including the N. E. extremity of the island, bordering on the Mediterranean and the strait of Messina, which separates it from Calabria; area, 1,768 sq. m.; pop. in 1872, 420,649. It is traversed from E. to W. by the Neptunian mountain range, and by the Monforte, San Antonio, and several other small streams. The mountains abound with wood. There are no large plains, but many valleys, which as well as the banks of the rivers are very fertile in wine, oil, nuts, and fruit of every sort, particularly lemons and oranges. The other principal products are silk, hemp, and flax. Some cotton of an inferior quality is raised for home consumption. The most important mineral product is sulphur. On the south a portion of the province skirts the base of Mt. Etna. It is divided into four districts and includes the Lipari islands. Among the chief towns, besides Messina, are Castro Reale, Milazzo, Patti, Randazzo, and Taormina. II. A city (anc. Messana), capital of the province, on the N. E. corner of the island, on the strait of Faro or Messina, here about 4 m. wide, 120 m. E. by N. of Palermo, and 45 m. N. E. of Mt. Etna; pop. in 1872, 111,854. The approach from the sea is of remarkable beauty, the city rising in the form of an amphitheatre, and the dazzling whiteness of the houses pre-
cient of which is the cathedral, and has also an arsenal, naval arsenal, archbishop's palace, summer house, custom house, a large hospital, two theatres, a lazaretto, and numerous convents and nunneries. Messina is the seat of an archbishop. The harbor, one of the finest in the world, is about 4 m. in circuit, and can accommodate the largest fleet. The imports are colonial produce, cotton and woollen fabrics, hides and hardware. The total exports for 1870 amounted to $8,636,500, of which lemons and oranges were valued at $2,904,225; olive oil, $2,308,853; essence of orange, lemon, and bergamot, $1,358,070; and raw silk, $176,780. Tartrate, limestone, almonds, and filberts are exported in considerable quantities. The total imports in 1870 amounted to $5,853,755. In the same year there were entered 1,284 steamers, of 763,022 tons, and 3,559 sailing vessels, of 360,214 tons; and cleared 1,274 steamers, of 745,900 tons, and 2,992 sailing vessels, of 324,421 tons. The principal manufactures are damasks and satins. Coral, taffy, and other fisheries are extensively carried on. Messina is defended by walls and bastions, a citadel, and many forts, and is considered a fortress of the highest importance, as commanding the strait of its name, and thus being the principal gate to Sicily from the mainland. A railway extends to Catania, 591 m., and another to Palermo is now (1875) in progress.—The origin and early history of the ancient city are involved in obscurity. It is believed to have been founded by colonists from Magna Grecia and Greece between 1000 and 800 B.C., to have made rapid strides in prosperity, and to have derived its name from a body of emigrants from Messene in Greece, the original name having been, according to Thucydides, Zancle, after the similar Greek word signifying a sickle (the form of the harbor). In 396, when it was celebrated for its flourishing trade, a Carthaginian army landed in Sicily and destroyed the city, which was immediately rebuilt by Dionysius of Syracuse, who expelled the invaders. About 280 it was seized by the mercenaries expelled from Syracuse on the death of Agathocles, who were called Mamarini, children of Mamers or Mars, and whom subsequently applied for assistance to the Romans; hence arose the first Punie war, in the course of which the city was taken by its allies, and thus became the earliest dependency of Rome beyond the Italian continent. Cicero calls it a very great and very rich city. In the civil war of 49-48 it was the station of a part of the fleet of Caesar, and Sextus Pompey after his defeat by the fleet of Octavius under Agrippa (39) made his escape from it with only 17 ships. During the middle ages Messina continued to be an important city. To avenge the massacres of Sicily, it was besieged in 1289 by Charles of Anjou, king of Naples, but relieved by Pedro d'Aragon and Roger de Lorria. In 1673 it submitted to Louis XIV., but he was compelled to withdraw his forces by the Dutch and Spanish fleet. In 1748 it was afflicted by the plague, and the great earthquake of 1783 destroyed and depopulated almost the whole city, and it has since been rebuilt upon a better plan. It suffered severely from an inundation in 1823. A revolutionary outbreak took place there in 1848, but the insurgents were put down by the Neapolitans (Sept. 7). The possession of Messina during the war of that year enabled the king of Naples to reconquer the island. Every attempt at a popular movement was punished with the utmost rigor, a strong garrison was continually kept there, and the fortifications of the place were strengthened. In 1860, however, after the victory at Milazzo (July 20), Garibaldi's army entered the town, and an agreement was soon after entered into by which the citadel and three forts were to remain in the hands of the latter, and the town and two forts in the possession of the Sicilians. The citadel was invested by Gen. Cialdini on March 7, and surrendered on March 13, 1861. The recent erection of a lighthouse, a mosque, and an agency for the massagerei matters; and the repair of the streets, have absorbed every vestige of ancient Messana except a colonnade whose stones could not be made available.

**MESTIZO**, a Spanish-American term for the mixed offspring of Europeans and Indians. In Mexico, Peru, and Brazil, mestizos are very numerous. Their color is almost a pure white, with a skin of remarkable transparency. The chief indications of the mixture of Indian blood are a thin beard, small hands and feet, and an obliquity of the eyes. The women of this race are called mestizas, and the offspring of their marriage with whites differ but slightly from pure Europeans.

**MÉSZÁROS, Lázár**, a Hungarian general, born in Baja, county of Bács, Feb. 20, 1796, died at Eywood, Herefordshire, England, Nov. 16, 1858. He studied law at Pesth, but in 1813, on the outbreak of the new war against Napoleon, he entered the Hungarian army in the service of the emperor Francis. He was in Italy as colonel of a hussar regiment in the spring of 1848, when he received the first information of the important changes in Hungary, and was soon after offered the ministry of war in the cabinet of Batthyány, and started for Pesth. Elected a member of the diet, he defended the moderate measures of the ministry. He went to the seat of war in the south, but failed in his attempts to storm the Rascian ramparts of Szent-Tamás (September). When Austria avowed the purpose of subjugating Hungary, he took the revolutionary side. In December he was sent to the north to check the advance of Schlick; but after an indecisive encounter at Sziksza (Dec. 28), his motley army suffered a total rout before Kaschau (Jan. 4, 1849). When the difficulties with Gorgéy compelled Kossuth to appoint a new commander-in-chief, the title was given to Mészáros and the real command to Dembinski, with whom
METAL (Gr. μεταλλία), a term including about 50 elementary substances which possess, either wholly or in part, certain well-marked physical and chemical properties, of which the most universal and characteristic is luster. The peculiar brilliancy and reflective power of the metals, which may be enhanced by polishing, results from their great opacity. The color of the metals is generally white with a grayish, bluish, or pinkish tinge; copper and gold are the only exceptions. In extremely thin films some of the metals allow the passage of certain rays of light. Gold leaf transmits light of a faint green hue. Most of the metals have a high specific gravity, a property which was regarded as characteristic until the discovery of the alkaline metals, which are lighter than water. With the exception of arsenic, they may all be fused, the temperature required for fusion ranging from 100° to the highest heat of the oxy-hydrogen blowpipe. Some of the metals may be volatilized. Mercury, the only liquid metal, is solidified at —39° F. Arsenic when heated passes directly into vapor without fusion. Most of the metals possess a certain mobility of particles that allows of their being extended or otherwise altered in form. The two nearly related properties of malleability and ductility, resulting from this, are not possessed by the metals in the same degree. A few of them, as antimony, arsenic, and bismuth, are decidedly brittle. Some assume a plastic condition before complete fusion, notably iron and platinum; on this property depends the operation of welding. The strength of the metals is very dissimilar, iron in the form of wire being about 26 times as tenacious as lead. They are all conductors of heat and electricity, although differing widely in this respect. The metals at present known, with the name of the discoverer and date of discovery of each, together with their atomic weights, are given in the following table:

</table>

With a few exceptions, the names and dates in the above list refer to the actual production of the metal. In many instances the metallic compounds were known and studied long before the metal itself was isolated. Some of the rarer metals have never been prepared in a pure form. Poldropium, formerly enumerated among the metals, has been shown to have no existence; and the existence of terbium is doubtful. The last four metals were discovered by means of the spectroscope.—The following tables exhibit the mutual relations of some of the more important metals in physical properties:

The physical properties of the metals are largely dependent on their purity and molecular condition, and on temperature. Hammered, rolled, or drawn metal generally has a higher specific gravity than cast metal. The state of molecular tension often induced by mechanical working, especially when cold, is resolved by annealing, i.e., heating and slow cooling. Most of the metals are more malleable and ductile at high temperatures. Commercial zinc is only malleable between 100° and 150° C.; at 200° it is so brittle that it can be pulverized. The conductivity for electricity is greatly diminished at high temperatures, and also by the presence of impurities in the metal. The addition of a small amount of a foreign substance often makes a metal harder, more rigid, and less susceptible of elongation. This is notably the case with iron, which when pure is soft and stretches considerably under strain before breaking, while steel, which is iron with a small amount of carbon, may be rigid and brittle. If reference be had to the original area of section, the rigid metal will show the greatest strength under a gradually applied tensile strain; but if to the fractured area, the purer metal is the strongest. The tenacity of metals generally decreases as the temperature is raised. The fusing points of the more refractory metals given in the above tables are approximate only, since trustworthy methods for determining high temperatures are wanting. The metals vary greatly in hardness. The alkaline metals are as soft as wax, while some, as chromium, will scratch glass. It is not improbable that extreme hardness in metals is produced by the presence of some foreign body, and is not inherent in the metal itself. Most of the metals are capable of assuming a distinctly crystalline form, generally belonging to the regular or isometric system. Some, as antimony and arsenic, crystallize in rhombohedrons. A few of the metals occur native; these are gold, platinum, palladium, iridium, and rhodium, which are almost exclusively found in the metallic state, and silver, copper, mercury, bismuth, arsenic, and antimony. Generally, however, the metals occur mineralized in combination with oxygen or sulphur. The specific heats of the metals, as will be noticed in the above tables, are inversely as their atomic weights, or, in other words, the specific heats of the atoms of the metals are equal. Chemically, the metals present very varied characters. As a class they are distinguished by the formation of compounds with oxygen which have basic characters, while the non-metals as a class form oxides which have acid characters. These two classes of oxides are capable of combining to form salts. While the oxides of the non-metals never form bases, the higher oxides of many of the metals have distinctly acid properties, and indeed a few of the metals form only acid oxides. The most stable compounds of tellurium, arsenic, antimony, tungsten, titanium, molybdenum, and vanadium with oxygen are acid in character and capable of combining with basic oxides. Those metals which seem to hold a position intermediate between the two classes have been termed half metals or metalloids. The latter term, however, is not generally used for all the non-metallic elements, viz.: hydrogen, oxygen, bromine, chlorine, iodine, fluorine, boron, nitrogen, phosphorus, selenium, silicon, sulphur, and carbon. Tellurium is closely related to sulphur and selenium, and is often classed with the metalloids; but its metallic appearance, and the analogy which its compounds bear to those of antimony, render its association with the metals equally appropriate. Hydrogen, although a gas and the lightest body known, resembles the metals in its chemical properties, and is capable of replacing them in combination. The formation of salts is regarded in modern chemistry as the replacement of hydrogen in the acid by a metal. —The metals are variously classified. A natural grouping, and one in common use, is: 1. metals of the alkalies; 2. metals of the alkaline earths; 3. metals of the earths proper; 4. metallic metals proper, whose oxides form powerful bases; 5. oxidable metals, whose oxides form weak bases or acids; 6. metals proper, whose oxides are reduced by heat, called noble metals. The strength of affinity of the different metals...
METALS

(Gr. metallon, working-metal, or useful stone, see Metals.)

METALLOIDS (Gr. metallon, useful stone, or working-metal, see Metals.)
valuable material attendant upon the additional manipulation required. To decide this question, for instance, with regard to an ore that is to be treated by smelting, it must be determined whether the expense of smelting the whole mass of the ore mined would be greater than that of first separating its worthless or injurious contents, and then smelting with better results the smaller quantity of concentrated materials; and also whether in the mechanical separation the loss of valuable material would be so great as to counterbalance the saving in smelting expenses, and the possible gain in purity of product and in completeness of extraction. It is also necessary to determine specially in every case how far the process of preliminary treatment shall be carried. It would not be desirable, even if practicable, to remove every trace of gangue, since some earthy material is requisite for the formation of slag to protect the metal in the heart of the furnace from oxidation. Simple concentration removes a portion of the worthless gangue, and divides the ore into two parts, usually called "headings" and "tailings." Headings may be made pure only by a loss of valuable material in the tailings; and, vice versa, the tailings can be made entirely worthless only by leaving considerable gangue in the headings. The best systems therefore involve the formation of one or more classes of so-called "middlings," or intermediate grades, which may be subsequently separated again. This principle is also important in the treatment of a material containing different ores which cannot be advantageously smelted together. Thus zinc blende, which is very commonly associated with silver-bearing galena, is often poor in silver, and moreover seriously embarrasses the lead-smelting, not only by requiring extra fuel for its own volatilization or fusion in the slag, but also by taking up and removing in its vapors or slags a larger portion of silver than it originally contained. Yet this mineral, if separated, can under favorable circumstances be profitably treated by itself. The mechanical separation of minerals depends either upon their magnetic properties or their specific gravity. The former principle has been employed to a limited extent in the separation of magnetic iron ores, in a finely divided state, from their accompanying gangue. Both permanent magnets and electro-magnets have been employed; but the process can scarcely be said to have proved an economical success, or to be now in practical operation outside of the laboratory.—Separation by specific gravity is performed in air and water. So-called dry concentrators are chiefly used in localities where water is scarce. The simplest form is that of a bowl or hide, in which auriferous dirt is placed and tossed in the wind, the lighter earthy particles being blown away, while the heavier sands containing the gold return to the vessel. Other air concentrators are winnowing channels, in which the material is separated by a draught of air, the heavier particles falling first to the floor, and the lighter ones being carried for longer distances; the result is a distribution of the materials on the floor of the channels in the order of their specific gravity. The most complete ore-dressing machines employing air are those in which the current of air is replaced by impulses, somewhat after the manner of the water jigs to be mentioned presently. The apparatus usually employed in dressing ores involves the use of water as a medium, and depends upon the relative periods occupied by bodies of different size, shape, and gravity in falling through water. The most favorable condition for separating ores would be the employment of a liquid exceeding in specific gravity one portion, and exceeded by the other portion, of the materials to be treated. The former would then float, while the latter would sink to the bottom, as in the preparation of fine porcelain clays. But in almost all cases the minerals to be separated sink in water, and a separation must be based on their different rates of sinking, dependent upon variations of specific gravity in different materials, and of size and shape of particles in the same material. In many machines for the separation of minerals by water, those particles which actually fall at equal rates will be brought together; hence, if it is desired to bring together particles of the same mineral (that is, of the same specific gravity) only, the disturbing effect of difference in size must be avoided. In other words, a careful sizing of the material must precede its separation according to gravity. A given quartz sphere will be 4 times as large in diameter, 68 times in volume, and 23 times in weight, as a galena sphere that falls through water at the same rate; and if such a piece of quartz were present with such a piece of galena in the material under treatment, they would not be separated. The separation is not usually effected in still water. In some machines the ore is made to fall against a rising current, or against impulses given by the motion of pistons; in others, the action of a stream of water passing through a trough or over an inclined plane is employed. The rousing is frequently effected beforehand by sieves, but the inclined plane itself may produce a separation according to the size of the particles, by reason of the greater rapidity of the upper surface of the stream, and the greater effect produced by the current upon larger particles. The shape has here an important influence, as determining the retardation of the particle by rolling or sliding friction. The apparatus in which still water is employed includes various kinds of settling tanks. The upward current and impulse is characteristic of the machines known as jigs; while the thin stream of water passing over an inclined surface is a feature of the bubble, the plane table, the rotary table, and the percussion table. The most universal- ly serviceable machine for ore dressing is the "jig" or "jigger." This was originally a simple improvement upon the treatment of ore by
hand on a sieve under water. By plunging the sieve down suddenly under water, and allowing the particles to come again to rest upon it, a separation is effected; and if the stuff has been sized, and the operation has been repeated often enough, the denser particles are found in strata under the less dense. By scraping off the upper layers horizontally, ore and gangue may be separated. The first improvement was that of imparting motion by machinery to the sieve, but it was afterward found more convenient and effective to employ a submerged stationary sieve, and impart a vertical oscillatory motion to the water. This is done by using pistons or elastic diaphragms placed in the sides of the box, or on the top of a lower chamber full of water, and communicating with a lower box through the sieve. An additional feature of recent mechanical jigs is the continuous discharge, by means of which the different classes of separated material are removed without interrupting the operation. It was formerly supposed that coarsely crushed ores only could be effectively treated by jiggling; and since ores so crushed usually contain a large proportion of fragments composed of adhering gangue and ore, and therefore possessing a specific gravity different from both gangue and ore, it was supposed that the jig could not be employed for the most delicate separation. But the improvements which have been made in this apparatus permit the treatment by it of much finer material than was formerly practicable, and at the same time have greatly reduced the hand labor and consequently the expense involved in the process. The result has been a great extension of the application of the jig, and the gradual abandonment to a large extent of the more cumbersome buddles and tables, which were formerly considered necessary for the treatment of the finest sands. The "dolly tub" is a very simple machine for separating the particles of crushed ore. It consists of a cylindrical vessel filled with water, in which the ore is rotated by means of revolving arms. When rotation has been maintained long enough, according to the quality and size of the material, the ore is allowed to settle, while the workman jars the table by blows upon the side of the tub with an iron bar, to prevent adhesion upon the inner surface. This machine has been elaborated by Hund, Rittinger, and others, and provided with a continuous discharge. In the machines already described, the material to be worked must previously be carefully sized, but sometimes it is already too fine to be accurately or rapidly sized in sieves or "trommels," and for this reason resort is had to a different treatment. The material is first separated into "equal-falling" portions, grains constituting each portion being of such relative size and specific gravity that they will sink through water in equal times. Each of these portions is then treated alone upon a machine capable of separating the particles according to their specific gravity. For classifying the equal-falling particles, various machines are employed, in which use is made either of a horizontal stream of water of decreasing rapidity and of considerable depth, or a comparatively shallow, smooth stream, or a vertically ascending column with decreasing rapidity. The Spitzkasten or pointed box employs the first of these agencies. These boxes are hopper-shaped, and several of them of different sizes are connected. The water carrying the ore flows into and over the first box, and the heavier particles settle, while the lighter flow on to the second box, and so on. The rapidity of the current is diminished by varying the breadth of the boxes. The vertically ascending column of water is employed in the so-called Spitzkasten, a system of conical boxes, in which the water does not flow over as a covering current, but enters at the bottom. Both the flowing current and the stream of air have been combined in some recent forms of pointed boxes. The rifle, so frequently used in placer gold mining, involves the same principle.—The material, having been classified by any of the machines just mentioned into portions of equal-falling particles, must be treated further in order to separate each of these portions according to specific gravity; and for this purpose machines must be employed in which the particles will be affected more in proportion to size than in proportion to weight. Of equal-falling grays, the smallest are of course the densest; hence, the smaller will be mainly ore, the larger mainly gangue. A very thin, smooth stream of water, passing over a plane surface, exerts different forces upon large and small grains lying in the current. The friction on the layer of water next to the bottom is much greater than on the layer above. Hence large grains, the tops of which protrude into the layer above, will be acted upon by a much more rapid current, and will be moved forward, while the grains lying in the lowest layer are unaffected. This is incidentally also a separation according to gravity, since the large grains are specifically lightest. It is essential that the stream should be thin; a deep stream acts upon all points very nearly alike. Another requisite condition is a proper velocity, which depends upon the inclination of the plane. If too nearly horizontal, the current will not move even the coarser particles, and if too steeply inclined it will be so violent as to sweep away fine and coarse alike. The amount of material held in suspension must also be regulated; if the water is too muddy, it will not be free to act on the separate grains, and the grains will act on each other. Keeping the water perfectly clear will effect the most complete sizing, but this condition is unfavorable to the quantity of work performed. The economical medium is found by practical experiment. Among the machines employed for this purpose are the plane table, the buddle, and the percussion table. The first requires little description. It
is an inclined plane, near the head of which
the ore is deposited in the form of slime, and
acted upon by a stream of water distributed
uniformly over the board. To prevent the
cutting of furrows or channels in the ore bed,
the workman continually smooths and con-
solidates with a wire brush or piece of plank
the layer of concentrated ore deposited near
the head of the table. When the table is full
of accumulated ore, the water is shut off by
means of the ruffle, and the layer is divided
into four parts, or zones, parallel with the
head of the table. The upper zone is concen-
trated ore; the second zone is usually about
as rich as the original material; the third is
poor, but still rich enough to pay for re-
working; the fourth is too poor for further
treatment, and is rejected as tailings. Minor
subdivisions may sometimes be made to ad-
vantage. The manual labor involved in this
process has caused it to be more or less sup-
ported by mechanical contrivances. One of
these is the buddle, which may be consid-
ered as consisting of a large number of plane
tables placed radially round a central point.
They may be arranged with their heads to-
gether, the ore being fed in the centre and
discharged on the circumference, in which
case the buddle forms the frustum of a low
cone, and is called a convex buddle; or they
may be grouped with the tails toward the cen-
tre, the feed being on the circumference and
the discharge in the centre, constituting a con-
cave buddle. In these machines the tedious
operation of maintaining an even surface to the
ore layer is performed by revolving arms car-
rying brushes or scrapers. A concave buddle
is usually preferred, by reason of its discharge
in the centre, where the working surface is
smallest. This secures a maximum force of
current for carrying away the worthless ma-
terial; whereas on the convex buddle the cur-
rent is strongest in the centre, and is most
likely at that point to carry past the proper
zone particles of rich ore; while on the cir-
cumference, where the discharge takes place,
the current is so much spread out as to have
lost the power of carrying away the worth-
less portions of the material. The percussion
table is another improvement on the plane
table, in which the smoothing and consolida-
tion of the surface of the ore layer is effected
by means of a periodical jar communicated to
the table itself. This jar is ordinarily given by
suspending the table, swinging it from its posi-
tion of equilibrium, and allowing its backward
swing to be stopped by striking against a sta-
tionary block. The consolidation of the ore
by brushes on the buddle, already alluded to,
is not effective for very small particles. The
finest slimes, when treated in biddles, remain
too loosely on the surface, and permit the for-
mation of furrows or channels; but on the
percussion table the shock imparted to the
particles thoroughly shakes them together,
and consolidates the mass. The percussion
tables until recently employed were stopped
at intervals and cleaned up by hand, like the
ordinary plane table; and the biddles were
treated in the same way, the zones of classified
material in the latter case being of course an-
nular. But the most recent practice has given
rise to continuously working biddles and per-
cussion tables. The former are known as
rotating tables, and are substantially biddles
which revolve slowly under feeding spouts,
and from which the dressed ore, instead of
being allowed to accumulate on the table, is
washed off by clean water as soon as the sep-
oration of the grains has been effected. These
machines, as well as the continuous percussion
tables, were perfected by the late Herr von Rit-
tinger of Austria. The rotating tables have
been found somewhat complicated and waste-
ful of water, and require very careful and skil-
ful management; but the continuous percussion
tables are pronounced both cheaper and more
convenient than the similar machines of the
intermittent type. These continuous tables
receive their shock sidewise instead of end-
wise, and the result is a distribution of the ore
in peculiar curved zones upon the table. The
stuff to be washed is delivered upon the tables
at an upper corner. The clear water is fur-
nished by distributors. The tendency of the pulp
is to flow down the slope in a direct line;
but by means of the lateral percussion the path
of the heavier particles is changed, and they
are gradually thrown toward the side re-
sieving the shock. The combination of this
motion, at right angles to the current of water,
with the downward motion of the current,
gives to the particles, according to their size
and weight, a more or less curved path, and
gradually separates the heavier and richer par-
ticles from the poor stuff. By the time they
have reached the foot of the table the richest
portions have been transferred to the corner
diagonally opposite to that upon which they
entered, while the middlings and tailings are
discharged along the lower edge of the table,
in the order of their concentration. By pla-
cing compartments below the edge of the table,
to receive the different discharges, the product
of the classification are conducted away sepa-
rately. The best authorities on this subject are
the elaborate treatises in German by Rittinger
and Gätzschmann. II. EXTRACTION OF MET-
ALS FROM THEIR ORES. The chemical processes
employed for this purpose depend, 1, on the
affinity of carbon for oxygen; 2, on the mu-
tual reaction of an oxide with the sulphide of a
metal; and 3, on the replacement of one metal
in combination by another. The reactions in
1 and 2 take place only at high temperatures,
while those in 3 may be effected either by
fusion or in solution—1. Metals reduced from
the state of Oxide by Carbon. The affinity
of carbon for oxygen at high temperatures is
sufficient to decompose most of the metallic
oxides. Even the alkaline metals may be
thus obtained. A few of the oxides (alkaline
earth, earths, &c.) cannot be reduced by carbon, but their chlorides are reduced by the alkaline metals. In ordinary metallurgical practice the naturally occurring oxides that are reduced by carbon are iron, tin, zinc, and lead. The ores of iron and tin are exclusively oxidized. Zinc occurs both in oxidized condition as carbonate or silicate, and also as sulphide. Lead exists mainly as sulphide, but occasionally as carbonate, phosphate, &c. Metallic zinc is always produced from the oxide; the sulphide must therefore first be converted into oxide before it can be treated for the reduction of the metal. Lead may be prepared both from the oxide and the sulphide, and according to the process employed the sulphide is either treated as such (see below) or oxidized by roasting. The methods employed for reduction by carbon consist either in heating the oxide in direct contact with coal or in exposing it to the action of heated carbonic oxide gas. Iron ore is smelted in a high-shaft furnace, and is reduced entirely by carbonic oxide generated by the partial combustion of the fuel in the lower part of the furnace, where the metallic iron is melted. Tin ore is either smelted in a low-shaft furnace or on the hearth of a reverberatory furnace in contact with fuel. Oxidized lead ore is likewise treated in shaft furnaces. Zinc ore is mixed with fuel and heated in clay retorts. Since the reduction of iron ore is effected at a temperature below the point of fusion of the metal, the latter may be obtained in the solid state having the form of the pieces of ore used (iron sponge); but as ordinarily smelted the metal is fused after reduction. In this fusion it combines with carbon and silicon and forms cast iron. This product, although containing only about 93 per cent. of iron, has manifold applications in the arts. In the preparation of wrought iron, which is nearly pure, cast iron is submitted to an oxidizing smelting to remove the carbon and silicon. Tin and lead are reduced at temperatures above their points of fusion, and are obtained in a molten state, while zinc is only reduced above its boiling point, and is obtained as vapor, which is condensed to a liquid.—2. Metals produced by the mutual Reaction of an Oxide and Sulphide. This reaction results, in the case of a few metals, in the formation of sulphurous acid gas and the separation of the metal, according to the following general formula: \[ \text{MS} + 2\text{MO} = 3\text{M} + \text{SO}_2. \] The principal examples of this mode of smelting are lead and copper. The sulphides of these metals are partially oxidized, and the oxide thus formed is intimately mixed at a high temperature with the unaltered sulphide, with the result given above.—3. The Replacement of one Metal by another. The chemical affinity which the metals possess for the non-metallic elements differs greatly, and those possessing the strongest affinity are capable, in many instances, of driving the weaker out of combination. Advantage is taken of this in the separation of many of the metals. When sulphide of lead is heated with metallic iron, metallic lead is produced with sulphide of iron, owing to the stronger affinity of iron for sulphur. Antimony is reduced from its sulphide in the same way. This replacement of one metal by another is still more readily accomplished when the metal to be separated is in solution. It is only for the more valuable metals, as gold, silver, and copper, that the so-called wet processes, in contradistinction to the dry or smelting processes, are employed. Silver is produced in both ways. When associated with lead it is smelted by either of the lead processes given above, and is obtained alloyed with the lead. But when the ore or smelting product from which the silver is to be extracted is free from lead or nearly so, the silver may be converted into sulphate and dissolved out by water, or into chloride and dissolved either by a solution of chloride of sodium or hyposulphite of soda or lime. From these solutions the silver may be precipitated by iron or copper, or it may be thrown down as sulphide and this decomposed by iron. Rich silver ores (sulphides) are sometimes added directly to the molten lead in the process of cupellation, in which case the silver is reduced by lead. Copper is also produced to a considerable extent by wet processes. It is rendered soluble by dissolving the native oxides or carbonates, or the oxide produced by roasting the sulphide by acid, and is precipitated by metallic iron. In gold and silver extraction processes, mercury is largely used to collect the finely divided metals, since it combines with them readily, forming an amalgam. When the metals occur native in the ore, they may be directly extracted with mercury. Some natural compounds of silver are decomposed by simple trituration in an iron pan or mortar. If mercury is present, the silver is taken up as soon as set free. In the more refractory ores the silver is converted into oxide or chloride by roasting before treating with iron and mercury. Metallic gold may be rendered soluble and extracted from its ores by means of chlorine. From the solution thus obtained the gold is precipitated by iron (iron vitriol). The production of mercury from its principal ore (sulphide or camaron) does not involve any of the three processes given above. The ore is simply heated with access of air, when the sulphur is oxidized to sulphurous acid and the metal liberated in the form of vapor. (For detailed accounts of processes see the articles on the different metals.)—Not unfrequently an ore after dressing may contain several metals, and the processes involved in the extraction and separation may be very complicated and include the operations of all three classes given above. (See Reducing smelting process under Lead.) The amount of a metal in an ore is often so small that it is necessary to subject the ore to a concentrating process before it is treated for the extraction of the metal. Thus
copper ores which may contain 5 per cent. or less of metal are worked by a process known as matte smelting, whereby the copper is raised to 70 or 80 per cent. by the removal of earthy ingredients and iron. In this process the copper in the ore is collected in a matte which is mainly a combination of iron, copper, and sulphur. The iron is gradually removed in successive operations, until only copper and sulphur are left. From this enriched product the copper is separated by the roasting-reaction process. (See Copper.) Nickel ores are likewise first smelted to a matte.—The furnaces employed for metallurgical operations may be divided into the shaft or blast furnace, the gas or reverberatory furnace, and the crucible. In the shaft furnace the ore or other metallic compound is charged alternately with the fuel, and a reducing atmosphere, that is, one in which carbonic oxide predominates, always exists. In a reverberatory furnace the fuel does not come in contact with the hearth of the furnace, on which the substance to be heated is placed. The atmosphere here is generally oxidizing, owing to the practical impossibility of obtaining a high temperature without the admission of a slight access of air. In gas furnaces the access of air can be better regulated than with the ordinary reverberatory, but it must not be overlooked that carbonic acid, the product of combustion, gives off oxygen to some metals (as iron) at a red heat. Where a low temperature only is required, a more or less reducing atmosphere may be maintained by limiting the supply of air. But when an active reducing action is required on the hearth of a reverberatory furnace, the substance to be treated is intimately mixed with coal. A covered crucible or retort heated from without is entirely independent of the source and character of the heat, and consequently the nature of crucible smelting depends solely on the substances employed.—The earthy matters associated with the metals in ores are removed in ordinary smelting operations in the form of a fusible compound, which when solidified is generally hard and stony and is called slag or cinder. In iron smelting the slag consists mainly of silica, lime, and alumina. It is rarely the case that an iron ore contains these substances in the proper proportion to form a fusible cinder, and consequently the substance which is deficient must be added. As most iron ores are silicious, limestone is usually added as flux. In copper and lead smelting, the cinder usually contains, besides the earthy bases, a considerable amount of iron in the form of ferron oxide. The cinder from copper matte smelting is almost exclusively a ferrous silicate. Mill cinder produced in the operation of puddling pig iron is also a ferrous silicate, but the iron contained in it is the incidental and unavailable result of the oxidizing atmosphere in the furnace necessary for the removal of the silicon and carbon; it does not therefore represent an enriched product, but a waste of iron.—In order to facilitate the extraction of the metal, it is often necessary or desirable to change the physical or chemical constitution of the ores. This is effected by roasting or calcination. Roasting in its simplest form consists merely in the exposure of the ore to heat, in order to render it friable and porous and thereby more readily reducible. Compact iron ores are often thus treated. Again, an ore may contain volatile ingredients which can be driven off by heat. It becomes thereby enriched, besides being rendered porous. The apathic ores of iron (carbonates) and the brown hematites (hydrates) when heated part with their carbonic acid and water, and are converted, the former into porous magnetic oxide, and the latter into red oxide. This kind of roasting, generally called calcination, is usually affected in low-shaft furnaces or kilns, the heat being generated by fuel charged with the ore, or by the use of gas. The sulphides and arsenides of the heavier metals are often roasted in order to break up existing combinations and to form others which are more susceptible to treatment. This roasting may be either oxidizing or chloridizing. Oxidizing roasting consists in subjecting the ore, or other metallic combination, as matte, in the form of lumps or powder, to the action of heat, with free access of air. It is sometimes conducted in heaps in the open air by piling up lumps of ore or matte with layers of fuel. When sufficient sulphur is present, the pile when once ignited continues to burn without the aid of fuel. This method is always tedious, and generally imperfect. The ordinary method of furnace roasting consists in exposing the ore in the form of powder to the action of heat and air on the hearth of a reverberatory furnace. The ore must be frequently turned and rabbled, so that the oxidation shall proceed uniformly. It is also necessary to avoid a temperature which would either sinter or fuse the mass, and thus hinder the complete exposure of the small particles to the air. To obviate the necessity of hand labor in turning the charge, and also to hasten the roasting, mechanical appliances have been employed, such as revolving chambers and hearths. It has also been found that showering the ore or matte in fine powder into a heated chamber or stack is a very expeditious method of roasting. Gerstenhöfer was the first to introduce this practice. His furnaces are rectangular chambers provided with iron bars of triangular section arranged at regular intervals, base uppermost. The time of exposure in falling is thus somewhat prolonged. The sulphides of the different metals behave very differently when roasted. In general the metal and sulphur are both oxidized; part of the latter passes off as sulphuric acid, which under favorable conditions can be utilized in the production of oil of vitriol; and part is converted into sulphuric acid, which combines with the metallic oxide. At a high temperature this sulphuric acid may be driven off, either wholly or in part, and the oxide left.
When arsenic and antimony are present, the reactions become much more complicated and complete roasting more difficult. Gold, mercury, and silver may be reduced to metal by roasting, owing to their feeble affinity for oxygen at high temperatures. Some sulphides are difficult to roast, owing to their fusibility (sulphides of lead, bismuth, antimony, &c.). Chloridizing roasting has for its object the conversion of silver in ore or matte into the condition of chloride, in which form it may be dissolved, or directly treated with metallic iron to separate the silver, as mentioned above. The chlorination of silver is effected by the addition of common salt to the charge to be roasted, which is decomposed by the sulphuric acid generated by the oxidation of the sulphur with the liberation of hydrochloric acid. The methods employed are in general the same as those used in oxidizing roasting. The revolving cylinder (Brückner's) and the showering furnace (Stetefeldt's, on the principle of Gerstenböfer) are largely used, and are found to give good results.—In many smelting operations, especially where ores of complex composition are used, an alloy of several metals is frequently produced. Thus the furnace or work lead from many ores contains copper, antimony, silver, gold, and other metals. The separation of the metals from each other is based on their relative oxidizability, on the solvent action of metals and metallic oxides on each other, on difference in fusible point, on crystallization, and on solubility in acids. Examples of these methods will be found in the accounts of the different metals. It will suffice here to mention briefly the separation of lead from silver by the oxidation of the former, and the removal of copper and other metals at the same time, by the solvent action of litharge on their oxides (cuppelling); the separation of silver from copper by alloying the latter with lead, and subsequently removing the lead with the silver by heat (liquation); the removal of silver from lead by zinc (Garbey's process) aided by crystallization (Pattinson's process); and the separation of silver from gold by acids.—Metals occur in the arts either cast as ingots or in finished forms, or wrought by hammering, rolling, and drawing into sheets, rails, wire, &c. These mechanical processes are intimately connected with and dependent upon the physical properties of the different metals and on their purity.—See “Elements of Metallurgy” by J. Arthur Phillips (London, 1874).

**METASTASIO.** Pietro Antonio Domenico Bonaventura, an Italian poet, born in Rome, Jan. 3, 1698, died in Vienna, April 12, 1782. He is said to have excelled in improvising verses at the age of 10. Gravina, an eminent jurist and scholar, adopted him as a son, changing his name of Traspasi to that of Metastasio (from the Gr. μετάστασις, change or transfer), and preparing him for the profession of the law, but without discouraging his studies in classical and dramatic literature, in which he advanced so rapidly that at 14 he wrote a tragedy, Giulietta, after the Greek model. He accompanied his patron to Naples, where his talents gained him many friends. While continuing the study of jurisprudence, he took holy orders, whence he was sometimes called Abbate. Gravina bequeathed him in 1718 a considerable fortune; but the young poet squandered most of it within two years, and again applied himself to the study of the law. Soon returning to his favorite pursuit, he produced an epitaphianum and the drama Endimione. Under the patronage of the viceroy of Naples he wrote Glierti esperidi and Angelica, the latter after Ariosto. The part of Venus in the former play was performed by Maria Bulgarini, or La Romanina, who was at that time the leading Neapolitan prima donna, and whose appreciation of Metastasio's genius laid the foundation of a most intimate relation, the poet writing under her inspiration his Zerdenardo (1724), which was set to music by Sardi and other composers, and established Metastasio's fame. He accompanied the signora to Rome, where his Semiramide (set to music by Meyerbeer in 1819), Ezio, Alessandro nell' India, Catone in Utica, and Artaserse were performed in rapid succession. In 1729 he went to Venice, where he succeeded Zeno as imperial laureate. In 1738 appeared his Olimpide; and one of his most celebrated lyrical dramas, La eleuenda di Tito, was performed in 1754, and was again set to music in 1790 by Mozart. The death of the emperor Charles VI. in 1740, and the outbreak of war, led to the closing of the theatre in which he had been employed, and he now devoted himself to literary pursuits, chiefly to translations and annotations of Greek writers. In 1744 appeared his plays of Antigone and Ipermnestra. After the return of peace he wrote Il re pastore (1751), which was enacted by the ladies of the imperial family. His last operatic play, Il Ruggiero, was produced at Milan on occasion of the marriage of the archduke Ferdinand (1771). His last occupation was the superintendence of the magnificent Paris edition of his works. Metastasio was among the first to recognize the genius of Mozart, and to express his admiration of a comic opera which the composer, then only 12 years old, had set to music in 1768. His best known oratorios are La morte d'Alebe, Isacco, and La passione; and his most popular cantatas are La liberta, La primavera, and La partenza. A catalogue raisonné of his compositions is given by Dr. Burney. The best editions of his works are those in 12 vols. (Paris, 1780–82), and 20 vols. (Mantua, 1816–20).—See Burney, “Memoirs of the Abbate Metastasio,” with translations of his principal letters (3 vols. 8vo, London, 1796). The best Italian sketch of his literary career is by Mauro Boni in his edition of Metastasio's works (Padua, 1811). His “Dramas and Poems” were translated into English by J. Hoole (3 vols., London, 1800).
METASTASIS (Gr. μεταστάσεις, translation), a change in the seat of a disease, attributed by the humorists to a translation of the morbid matter from a part previously diseased to another, and by the solidists to a translation of the irritation. It has been a matter of dispute whether such an action as metastasis really ever takes place, or whether it is not simply an extension of the disease. The frequent sudden transference of the seat of gout and acute rheumatism would seem to favor the idea that there is change of seat without any progressive extension. There are some diseases, however, which were formerly considered as metastatic, that have been shown to be properly not so classified. (See MILE LEO.)

METCALFE, a S. central county of Kentucky, watered by Big and Little Barren rivers; area, about 500 sq. m.; pop. in 1870, 7,934, of whom 861 were colored. The surface is rolling and the soil fertile. The chief productions in 1870 were 38,818 bushels of wheat, 276,207 of Indian corn, 62,462 of oats, 1,310,581 lbs. of tobacco, 17,718 of wool, 54,550 of butter, and 1,045 tons of hay. There were 2,327 horses, 1,368 milch cows, 2,385 other cattle, 8,701 sheep, and 12,966 swine. Capital, Edmonton.

METCALFE, Frederick, an English clergyman, born in 1817. He graduated at St. John's college, Cambridge, in 1836, and subsequently was elected a fellow of Lincoln college, Oxford. In 1848 he became head master of Brighton college. He has published "The Oxonian in Norway" (2 vols., 1856); "The Oxonian in the Thelemarken" (2 vols., 1858); "History of German Literature" (1858); and "The Oxonian in Iceland" (1861). He has adapted from the German of A. Becker sketches from the domestic life of the ancient Romans and Greeks, under the titles "Gallus" (1854; 2d ed., 1853) and "Charicles" (1845; 2d ed., 1854).

METELLUS, a Roman plebeian family of the Caecilia gens. The following are its most distinguished members. I. Lucius Caecilius, commander against the Cartaginians in the first Punic war, defeated Hasdrubal in 250 B. C., and was honored with a triumph. He was twice consul, once dictator for the purpose of holding the comitia, and pontifex maximus during the last 22 years of his life. He lost his sight while rescuing the Palladium from fire, and died about 220. II. Quintus Caecilius, son of the preceding, served successively as plebeian aedile, curule aedile, consul, proconsul, and dictator for the purpose of holding the comitia. He fought in the second Punic war against Hasdrubal in Spain, and against Hannibal in Bruttium, and survived the final victory over the Carthaginians many years. III. Quintus Caecilius Metellus Macedonicus, son of the preceding, commanded as prator in Macedonia, where he defeated and made prisoner the usurper Andriuscus (148), fought successfully against the Achaeans (146), and as consul against the Celtiberians in Spain. He was consul in 131, died in 118, and was carried to the funeral pile by three sons who had officiated as consuls, and a fourth who was candidate for the same dignity. The first, second, and fourth were afterward distinguished by the surnames of Balericus (from the conquest of the Balearic isles), Diadematus, and Caprarius. IV. Lucius Caecilius Metellus Dalmaticus, nephew of the preceding, officiated as consul, censor, and pontifex maximus, received his surname from his victories over the Dalmatians in 119, and was active against Sarturinus 19 years later. V. Quintus Caecilius Metellus Numidicus, brother of the preceding, commanded as consul in 109, and as proconsul in the following year, against Jugurtha in Numidia, but had the mortification to see the fruit of his victories, the honor of a final triumph over the enemy, snatched from his hands by Marius, his legate, who supplanted him in the opinion of the Roman people, and was elected consul to succeed him in command. He was, however, allowed a triumphal entry into Rome (107), and subsequently elected censor (102). Two years later Marius concerted with the tribune Saturninus a scheme to destroy the influence of Metellus, who was regarded as the foremost leader of the aristocratic party. Saturninus moved and carried through an agrarian law, with an additional enactment requiring the senators to take an oath of fidelity to the same, under penalty of being expelled the senate. Metellus remained faithful to his convictions, suffering with calm resignation not only expulsion from the senate, but banishment from Rome. He retired to Rhodes, whence he was recalled in the following year. His orations are praised by Cicero, and were still admired in the time of the Antonines. VI. Quintus Caecilius Metellus Plus, son of the preceding, received his surname from his filial efforts to bring about the recall of his father from exile. He commanded in the second war, tried in vain to save Rome from Marius and Cinna in 87, crossed over to Africa, and subsequently fought against the Marian party in Umbria, Cisalpine Gaul, and Spain, where his efforts proved insufficient against Sertorius. He was consul with Sulla in 80, and died while pontifex maximus, being succeeded by Julius Caesar (63). VII. Quintus Caecilius Metellus Celer, great-grandson of Metellus Macedonicus, served as legate under Pompey in Asia, and as prator in Italy in the year of Cicero's consulship (63), with whom he actively cooperated against Catiline and his followers. On the outbreak of the war, being intrusted with the command in Picenum and the Senonian district in upper Italy, he greatly contributed to the defeat of Catiline by blocking up the passes of the Appenines, and thus compelling him to face the army of Antonius, Cicero's colleague. In 62 he was sent as proconsul to Cisalpine Gaul, in 60 officiated as consul with Afranius (opposing the schemes of Pompey), who was better served by his colleague as well as by his younger brother Ne...
METEMPSYCHOSIS

pos), and died in the following year, it was suspected from poison administered by his profligate wife Clodia. VIII. Quintus Caecilius Metellus Plus Scipio, the adopted son of Metellus Plus. (See Scipio.) IX. Quintus Caecilius Metellus Creticus, received his surname from the conquest of Crete, whither he was sent as consul in 69, and whence he returned in 66, but was prevented by his political opponents from celebrating a triumph till after the defeat of Catiline, during whose agitation he had prevented an insurrection of the slaves in Apulia.

METEMPSYCHOSIS (Gr. μετάρ, denoting change, and ψυχή, soul), the supposed transmigration of the soul from one body to another. It is a feature in Brahmanism and Buddhism, which represent the migration after death into the body of a higher or lower animal as a reward of virtue or penalty for vice. The soul may even deteriorate into the vegetable or mineral world. According to Herodotus, the Egyptians were the first to entertain this doctrine. They believed that the soul was clothed successively with the forms of all the animals that live on the earth, and that it then returned after a cycle of 3,000 years into the body of a man, to recommence its eternal pilgrimage. The later Pythagoreans maintained that the soul has a life peculiar to itself, which it enjoyed in common with demons or spirits before its descent to the earth, and that there must be a degree of harmony between the faculties of the soul and the form which it assumes. Plato adopts and treats the doctrine in his "Phaedo," maintaining the preexistence of the soul before it appears in man, of which condition it retains dim reminiscences; and after death, according to its peculiar qualities, it seeks and chooses another body. Every soul, according to him, returns to its original source in 10,000 years. After completing each life it spends 1,000 years in the infernal world in a condition corresponding to that life. The idea appears in the speculations of the Neoplatonists, and in the cabals of the Jews. Porphyry gave to it its most definite development in Neo-Platonic thought. The cabalists thought that the destiny of every soul was to return into mystical union with the divine substance, but that in order to do this it must first develop all the perfections of which it has the germ within itself. Origen, in his work "On Principles," is supposed to hold this doctrine; to find in it the final cause of creation, and to maintain that God gave existence to the world as a place of purification for those souls which had sinned in heaven; and this explains why the Deity introduced so many apparent imperfections into his work. But Origen's book exists only in the Latin translation, De Principiis, by Rufinus, who is believed by modern critics to have altered the original, and to have interpolated some of his own notions. This idea, attributed to Origen, was also held by the Gnostics and Manicheans, and by the druids, and is still believed by the Druses.

METEOR (Gr. μετέωρος, lofty, in the air), any phenomenon of short duration occurring in the atmosphere. Rain, snow, hail, fog, and dew are meteors distinguished as aqueous; the movements of the winds constitute the varieties of aerial meteors; luminous meteors are the singular phenomena displayed by the action of the aqueous particles diffused through the atmosphere upon the rays of light, such as fata Morgana, halo, mirage, rainbow, &c., and may also include the aurora borealis; and igneous meteors are such phenomena as lightning, aerolites, shooting stars, &c. Most of these are described in this work under their own names. In common language, the term meteor is applied only to those bodies which, as globes of fire or as shooting stars, are occasionally seen darting through the heavens at unknown distances from the earth, and in undetermined paths. Sometimes exploding and projecting upon the earth fragments of stone called meteoric iron, they are proved to be solid bodies in a state of intense heat, and are then known as aerolites or meteorolites. In ancient times these bodies were witnessed in different parts of the earth, and their appearance was chronicled as among the most wonderful natural exhibitions. The Chinese records of such phenomena extend back to 644 B.C.; and from the 7th century B.C. to A.D. 338, 16 falls of aerolites are recorded in the astronomical annals of the Chinese. By the Greeks and Romans in the same period accounts are preserved of only four such falls. Humboldt says that it is remarkable that the Ionian school, in accordance with the present opinion, early assumed the cosmical origin of meteoric stones. Anaxagoras of Clazomenae held that the meteors are masses torn away from the earth by the violence of the rotation; and that between the earth and the moon there revolve other dark bodies, which can produce eclipses of the moon. Diogenes of Apollonia, as recorded by Stobaeus, also taught that dark masses of stone move with the visible stars and remain unseen by us. Plutarch in the life of Lysander (cap. xii.) expressly declares that falling stars "are really heavenly bodies, which from some relaxation of the rapidity of their motion, or by some irregular concussion, are loosened and fall, not so much upon the habitable part of the globe as into the ocean, which is the reason that their substance is seldom seen." The nature and movements of the meteoric bodies which fall upon the earth have already been considered under ΑΕΘΟΛΑΙΟΥΜΕΝΑ. But some of the most extraordinary meteoric displays, of the nature of fire balls or bolides, and of shooting stars, unaccompanied by falls of stone, may properly be noticed in this place. The bolis is the fiery body from which aerolites are precipitated upon the earth; but many such bodies pass across the heavens, and sometimes explode and disappear, leaving behind no vestiges of their solid materials. They appear singly at irreg-
cular periods, and move with great rapidity across the sky, exhibiting sometimes a dazzling brilliancy, greater than that of the sun at noon; as remarked by Humboldt of one seen at Popayan in 1788. A luminous train follows them, and their path has been known to remain brilliant for several minutes after they have disappeared. Admiral Krusenstern, indeed, in his "Voyage," describes a fire ball the train of which shone for an hour after the body had disappeared, scarcely moving during this time. They send forth vivid scintillations and present various bright colors, and the same meteor is differently described as seen from different places. Often they divide into two or more bodies which move along together, and sometimes they explode with a report like heavy thunder. They are of various apparent sizes, occasionally exceeding that of the moon. On Feb. 6, 1818, one was seen in England about 2 P. M. descending vertically and shining with a light equal to that of the sun. Dr. E. D. Clarke, who described this in the "Annals of Philosophy," vol. xi., p. 273, was of opinion that meteorites fell from this body; and in Lincolnshire it was reported that a hissing noise accompanied it, and a trembling of the earth was felt like the shock of an earthquake. The records of fire balls seen in the evening are very numerous. They appear at no particular season, and are limited to no particular portions of the earth, though most of the observations have been recorded in Europe. In 1693 one was seen over Germany, and described by Kepler. In 1876 one passed over Italy from the direction of Dalmatia about two hours after sunset, and disappeared toward Corsica. At Leghorn it was heard to explode, and fragments from it fell into the sea. Its height was estimated by Montanari at 38 m. Halley describes in the "Philosophical Transactions," No. 360, a meteor of extraordinary brilliancy which appeared over England in 1719 about 84 P. M. It suddenly illuminated the streets of London, causing the stars to disappear, and the moon, which before was shining brightly, to be hardly visible. The eye directed toward it could scarcely bear its brilliancy. It moved like a falling star at a height estimated at 60 to 70 m., and with a velocity of 300 to 350 m. in a minute; through Devon and Cornwall and on the opposite coast of Brittany a loud explosion was heard proceeding from it. On Aug. 18, 1783, at 9 P. M., another very remarkable meteor of this character was seen over a large part of Europe from the north of Ireland to Rome. It crossed the zenith at Edinburgh, appearing single and well defined, of a greenish shade, and with a tail; but at Green- wich it had the appearance of two bright balls with other luminous bodies following it. Its height was estimated to be above the limits of the atmosphere, its speed more than 1,000 m. a minute, and its diameter more than a mile. Cavallo describes its bursting and the noise of the explosion, which was 10 minutes in reaching the earth. Bowditch describes, in the "Memoirs of the American Academy," a meteor seen Nov. 21, 1819, at Danvers, Mass., and in Baltimore, Md., the diameter of which appeared to be half a mile. Its direction was 84° W., and its height, at first 38 m., was soon reduced to 22 m. Two minutes after its disappearance a rumbling noise was heard which lasted longer than a minute. On the evening of July 20, 1860, about a quarter before 10 o'clock, a meteor passed over the state of New York, from the west, being seen on Lake Erie, and soon afterward at Buffalo, Albany, New York city, New Haven, Newport, R. I., and New Bedford, Mass. At the south it was visible in the state of Delaware. By many observers it was at first supposed to be a display of rockets or of Roman candles; and all had the impression that its elevation was only a few hundred feet. From a vessel off Sandy Hook it appeared to fall into the sea at a short distance. First appearing as a single body, it was observed to separate into two balls, which kept along together, emitting sparks and what appeared to be flames. A table of meteors and meteoric showers given in Izam's "Lithologie astronomique" includes one of iron in Lucania, 54 B. O.; one of mercury (!) in Italy, of unknown date; a fall of about 1,300 stones, one of which weighed 160 lbs. and another 60, at Padua in 1510; sulphurous rains at Copenhagen in 1466 and in the county of Mansfeld in 1658, and a shower of sulphur at Brunswick in October, 1721; a shower of fire at Quesnoy, Jan. 4, 1717; one of sand lasting 15 hours in the Atlantic, April 6, 1719; and extensive showers of stones at Aden, July 24, 1790, and in France, May 15, 1864. (See Akaiothra.)—Falling stars resembling small balls are often seen in a clear night shooting at the rate of four or five an hour across the sky. These are termed "sporadic" meteors, in contradistinction to the "periodic," which at certain periods appear often in vast numbers like showers of fire. Displays of this kind are recorded as occurring in October, 902; Oct. 19, 1202; and Oct. 21, 1866 (O. S.). Each time the stars are said to have been in motion all night, falling like locusts, and in numbers which no one could count. More modern occurrences of this phenomenon were observed on the night of Nov. 9-10, 1787, in southern Germany; and on the midnight of Nov. 13-14, 1799, as described by Humboldt and Bonpland, in Oumañá. The same phenomenon was also observed as far south as the equator, and over North America, even to Labrador and Greenland, and on the other side of the Atlantic in Germany. From the bearing and course of the meteors at different points, their elevation was computed to be 1,419 m. In 1818 meteoric displays of great brilliancy were seen on the same night of Nov. 12-13, in England, and again in 1889 at Potsdam in Brandenburg. In some of the exhibitions about this period a deposit of dust was observed upon the surface of the water,
on the buildings, and other objects. On the same night in 1831 and in 1832, the same phenomenon reappeared in Europe and America. But the year 1833 is memorable for the most magnificent display on record. This was on the same night of November also, and was visible over all the United States, and over a part of Mexico and the West India islands. Together with the smaller shooting stars, which fell like snow flakes and produced phosphorescent lines along their course, there were intermingled large fire balls, which darted forth at intervals, describing in a few seconds an arc of 30° or 40°. These left behind luminous trains, which remained in view several minutes, and sometimes half an hour or more. One of them seen in North Carolina appeared of larger size and greater brilliancy than the moon. Some of the luminous bodies were irregular, and were seen stationary for a considerable time, emitting streams of light. At Niagara the exhibition was especially brilliant, and probably no spectacle so terribly grand and sublime was ever before beheld by man as that of the firmament descending in fiery torrents over the dark and roaring cataract. It was observed that the lines of all the meteors if traced back converged in one quarter of the heavens, which was γ Leonis Majoris; and this point accompanied the stars in their apparent motion westward, instead of moving with the earth toward the east. The source whence the meteors came was thus shown to be independent of the earth's rotation and exterior to our atmosphere. As computed by Prof. Denison Olmsted of New Haven, it could not have been less than 2,238 m. from the earth. Three successive annual returns of this phenomenon on the same night led astronomers on both sides of the Atlantic in the following years to watch for its recurrence; and displays more or less brilliant, but not by any means equal to that of 1832, were witnessed in various places in Europe or America every year till and including 1839. They were again observed on the night of Nov. 12-13, 1841 and 1846, and again in 1856 and every following year till 1871 inclusive. But it is not alone in November that periodic exhibitions of the fall of meteors have been observed. It is found that they often occur about the 10th or from the 9th to the 14th of August; and Humboldt named other periods that are likely to prove of the same nature; as about the 24th to the 25th of April, between the 6th and 13th of December, the 27th and 29th of November, and about the 17th of July. He noticed the singular coincidence which different observers have remarked in the great brilliancy of the aurora borealis during the fall of the meteors. Prof. Olmsted early suggested that the meteors probably emanate from a nebulous body, which revolves around the sun in an elliptical orbit, the aphelion of which meets the orbit of the earth at the times of the annual exhibitions. The nebular character is inferred from the fact that none of the meteors, though they fall toward the earth with prodigious velocity, ever reach it in a solid state, all being dissipated in the atmosphere, and no material substance found to indicate their nature. Arago adopted a view similar to that of Olmsted. He suggests that the meteoric bodies may constitute a stream in the form of an annular zone, within which they pursue one common orbit; that there are several such streams, which intersect, each at its own period, the earth's orbit; and that through each the myriads of small cosmical bodies are irregularly dispersed. But the demonstration of the real orbits pursued by these bodies (at least in the case of the more remarkable periodical showers) belongs to the years following the display of Nov. 15-14, 1866. Prof. Newton of Yale college had predicted a great display of November meteors, such as had been seen in the years 1799 and 1833, for the year 1866; and he even announced as the probable hour of the display early morning in America. He was within a few hours of the truth, the display occurring during the early morning in Europe, and closing before morning began in America. European astronomers noted the point in the heavens whence the meteors seemed to radiate, not far from the star γ Leonis, as in 1833. Then followed an inquiry into the orbit of the meteors. Prof. Newton had indicated five orbits as capable of explaining the recurrence of great displays about thrice in a century. Of these the three most probable were: first, a year and 1/2 part; secondly, a year less 1/2 part; and thirdly, 334 years. Prof. Newton considered the last named period improbable, because it implied an orbit extending beyond the orbit of the distant planet Uranus. He therefore regarded a period of rather more or rather less than a year as probably the true period of these meteors. But just at this time a remarkable discovery was made by Schiaparelli of Italy. Noticing that the comet II. 1862, passed the earth's orbit nearly at the place she occupies on Aug. 10-11, he was led to inquire whether the path followed by the comet resembled that traversed by the August meteors, assuming that they have the same period of revolution as the comet (about 124 years). He found the agreement so close as to leave no doubt of the existence of a real association between the August meteor and the large comet of 1862. This will be seen from the following comparison:

Astronomers therefore began to regard as not improbable the theory that the true period of the November meteors is about 334 years.
Peters, Temple, Leverrier, and other astronomers calculated the path on this assumption, and then they inquired whether any known comet possesses a similar path. By a singular coincidence, a telescopic comet had been found that very year, 1866, which traversed an orbit so near to that obtained for the meteors as to leave no doubt of the identity of the two orbits. The comparison is as follows:

But the matter was removed from the region of mere probability by the researches of Prof. Adams, the well known English astronomer. Analyzing the perturbative effects of the planets upon the members of the November meteor system, on the various assumptions pointed out by Prof. Newton as mentioned above, he found that the actual changes taking place in the position of the meteors' node (changes indicated by the gradual alteration of the date of the shower) imply an orbit extending so as to bring the meteors under the disturbing influence of the giant planets. Hence the recurrence of great displays thrice in a century can only be explained by the last assumption of Newton, assigning to the meteors a period of 35 1/2 years or thereabouts. Adams selected a period of 33 1/2 years, and found the nodal changes satisfactorily accounted for. Since then the identity of another system, the meteors of Nov. 27-29, so far as their path is concerned, with the short-period comet called Bie-la's, has been satisfactorily demonstrated, by the occurrence of a shower (predicted on that assumption) on Nov. 27, 1872. More than 100 meteor systems are now recognized, not in all or in most cases by the periodic recurrence of great displays, but by the existence of distinct radiant points. Even 10 or 12 meteors only, seen on the same night, can be safely assigned to a single system, when they are all found to radiate from nearly the same point of the star sphere.—There is every reason to believe that meteoric astronomy is as yet only in its infancy, and that the combined study of meteor systems and comets will throw great light on many most interesting subjects of astronomical research. Some of the researches of Prof. Kirkwood into the relations presented by comets seem very promising in this respect.

**Meteorology**

(Gr. μετεώρος, lofty, and λά-γος, discourse), the description and explanation of the phenomena peculiar to the atmosphere of the earth. On the atmosphere and its changes depend the development of life, both vegetable and animal, the currents and the navigation of the ocean, and even the great changes that have been wrought in geological ages by superficial disintegration and erosion. The consideration of these and kindred subjects gives rise to branches of science that may be considered as applications of meteorology proper, which should be restricted to the simple consideration of the atmospheric phenomena themselves, and the laws which produce them. As a science of observation, generalization, and induction, our present knowledge of meteorology dates from Aristotle; but as a deductive science, and one deserving to be ranked with astronomy, chemistry, and physics, its history is confined to the past 25 years. In this article we shall present in brief some of the more important general statistics, thus representing the results of the observations by which deductive theories must be tested, and shall conclude with a few words on the latter.

---

**Inductive Meteorology.** Our review of the inductive science will be divided into sections on the constitution, the temperature, the movement, the moisture, and the pressure of the atmosphere, in which arrangements we follow the very valuable treatise of Schmid.—

1. **Constitution and Properties of Air.** To Priestley and Scheele (1774) we are indebted for our first knowledge of the chemical constitution of the atmosphere as a mixture of oxygen and nitrogen; to these constituents Bergman, in the same year added carbonic acid gas as the third component; of the other gases that are present in very small quantities, excepting the vapor of water, it is not necessary to make further mention. The proportions by weight of the previously mentioned gases in the air over the Atlantic ocean are very nearly as follows: nitrogen, 77 per cent.; oxygen, 23 per cent.; carbonic acid gas, \( \frac{1}{8} \) of 1 per cent. The weight of one litre (61.027 cubic inches) of air, at 32° F., and a barometric pressure of 29.9 inches, is 1.293817 grammes (19.9569 grains), as determined by Regnault (1847). A unit's volume of dry air at the temperature of 32°, if free to expand, increases to 1.3665 on being heated to the temperature of 212°. The increased pressure experienced on heating from 32° to 212° a volume of dry air confined within the same space is in the ratio of 1 to 1.36706. The specific heat of air is usually assumed as unity, and the increase of temperature due to a sudden condensation of any portion of it into a smaller volume is about 10° for a diminution in volume of \( \frac{1}{8} \), assuming that the air originally is at a temperature of 32° and a pressure of 30 inches. The coefficient of viscosity of air is, according to Maxwell (1872), in British measures, 0.0625 at temperature 32°. The altitude and figure of the atmosphere are terms to which, strictly speaking, no exact definition can be given, since it is not yet certain that the rarefied gases in its upper portion do not merge by insensible degrees in the ether of interstellar space. On the other hand, the only portions of the atmosphere that have any important bearing upon meteorological phenomena are
those below which the phenomena of twilight, the aurora, and shooting stars take place, and these are generally confined to an altitude less than 100 m. above the earth's surface. At an altitude of 12 m. the air has a density one tenth of that which it has at the surface of the earth; that is, at that altitude the average barometric pressure would be three inches, and it is not likely that any changes take place at this height that are appreciable at the surface of the earth. The elevations of the mountains on the earth's surface bear a very appreciable ratio to the altitudes of the cloud-bearing and storm-producing strata of the air; in fact, these latter nearly all lie far below the summits of the highest ranges; and, as a consequence, the distribution of the elevated portions of the continents is a very important factor in meteorology. Of equal or even more importance is the relative position of the land and oceans. Not only is the ocean the principal source of the moisture in the atmosphere, but its influence is felt in a very different way. The power of absorbing and radiating solar heat is very great for all vegetable structures, such as the forests and prairies present; solid earth and rocks possess these properties in a far less degree, and even lower than these in the scale must be placed the ocean water. On the other hand, the specific heat of the earth is so much less than that of water, that the same amount of heat received from the sun upon each will affect the temperature of the air over the land nearly twice as much as that over the ocean.—2. Temperature. Atmospheric temperatures are almost uniformly measured by means of the mercurial or the spirit thermometers, the air thermometers being at present employed only in researches of extreme delicacy. (See THERMOMETER.) The heat found within our atmosphere may be considered as coming from six sources: 1, that peculiar to the interior of the earth; 2, that received at the earth; 3, that received from the sun; 4, that received from shooting stars; 5, that produced by friction of tides, winds, &c.; 6, that received from the sun; all which should be added to that originally possessed by the atmosphere. Considering the original heat as tending continually to be radiated and lost in space, the true meteorological problem is to determine how this loss is made up from the six sources just enumerated. 1. That the interior of the earth is in general warmer than the surface is shown by observations of temperature in deep springs, wells of water, and mines, and by the phenomena of volcanoes and geysers, and is very plausibly demonstrated by all seismological theories. (See EARTHQUAKE.) As an average for the whole earth, and especially applicable to the temperate zone, the temperature at a depth of 80 to 100 ft. is constant, showing that at this point we reach the surface of equilibrium between the conduction of heat from the interior outward, and the effect of the radiation from the earth's sur-

face. The only known exception to this rule is found in the northern portion of Siberia, where at a depth of 400 ft. the temperature is still 10° below the freezing point. On account of the slow conducting power of the materials of the earth, the superficial layer of 80 ft. in thickness should be viewed by the meteorologist not as a medium through which any important part of the interior heat of the earth is conducted to the atmosphere, but rather as a storehouse of the solar heat that enters into the ground, and thus equalizes the daily and annual changes of temperature. Nevertheless, the quantity of heat conveyed into the atmosphere by the circulation of air within mines, by hot springs, and by volcanoes, is perhaps barely appreciable, and is for the entire globe possibly equivalent to an elevation, of $\frac{1}{16}$ F. in the temperature of the entire atmosphere. 2. Since the earth is in the centre of a celestial vault thickly studded with stars, each of which radiates heat in all directions, its tendency is to assume a temperature higher than that which prevails throughout the interstellar spaces; the latter being estimated by Fouillet at about $-222$° F., while the temperature of the earth due to the stellar heat would be $-128$° F. 3. The heat radiated from the moon to the earth, though exceedingly small, has been measured by Lord Rosse ("Philosophical Transactions," 1873). The greater part of this heat is absorbed by the aqueous vapor of the atmosphere before it can reach the earth's surface. The principal effect of the lunar heat is therefore probably exerted in warming the upper layers of air, and in dissipating the clouds. The surface of the moon as heated by the sun attains to its maximum temperature a few days after the full moon, at which time its influence on the clouds and on the rainfall is probably barely appreciable at stations favorably situated, though Klein (1868) and Wierzbicki (1879) have shown it to be inappreciable in the interior of Europe. 4. The numerous shooting stars that enter the earth's atmosphere bring into it an appreciable quantity of heat, as is evident by their own combustion and dissipation; but as yet no accurate knowledge on this point is available. This heat is a simple case of the conversion of force into heat, and its amount could be calculated had we any positive information as to the mass of the meteors. 5. A small fraction of the energy of the earth's daily rotation is by friction converted into heat, which passes from the ocean to the atmosphere and exerts a slight warming influence. For the further consideration of this obscure subject, see Ferd., "Tidal Researches" (Washington, 1874). 6. Solar radiation produces on the earth both chemical and optical as well as thermal effects. This is subject to very slight fluctuations, connected in some unknown way with the variations of the solar spots; the frequency and extent of the latter vary in a period of 11 y years, and possibly also in a period of 55 or 68 years.
Attempts have been made to demonstrate other periods, of which perhaps the only one whose existence is plausible appears to agree with the time of rotation of the sun upon its axis. We are therefore justified in considering the intrinsic radiation from the sun as very approximately constant, and the diurnal and annual variations of terrestrial temperature depend upon the position of the station on the earth's surface, and the position of the earth's axis of rotation in reference to the annual orbit described by the earth about the sun. The quantity of heat received by any surface varies directly as the time of exposure and as the sine of the sun's altitude, and inversely as the square of the sun's distance. According to Lambert (1770) and Meech (1855), the sun's daily intensity is proportional to the cosine of the latitude. At either pole the intensity in midsummer is one fourth greater than on the equator; this arises from the fact that daylight on the equator lasts but 12 hours, while at the pole the sun shines throughout the whole 24 hours. In general, from May 10 to Aug. 3 the sun's vertical intensity over the north pole is greater than upon the equator. In the temperate zone the temperature of the air attains its maximum about one month after the maximum of the sun's intensity; in this interval therefore the earth must receive during the day more heat than it loses by radiation at night. The average annual intensity upon the whole earth's surface from pole to pole is 299 thermal days, the intensity of each of which units equals that of the mean equatorial day. The annual intensity of solar rays during 100,000 years, past or future, can never vary (owing to the varying eccentricity of the earth's orbit) more than the equivalent of five hours of average sunshine in a year. These conclusions refer to the whole earth's surface collectively. On the other hand, the annual intensity at the different latitudes on the earth varies much more considerably, and the extreme values of diurnal intensity may vary by as much as one ninth of the present value. It seems therefore that under the existing conditions of physical astronomy the intensity of solar heat upon the earth can never have been materially different from its present value.—In these rules we have considered only the heat received at the outer surface of the atmosphere from the sun, neglecting the absorption of heat by the earth's atmosphere and the radiation of heat back into space, two circumstances that materially affect actual temperatures. The absorption of heat in its passage through the atmosphere is directly found approximately by observations made with the pyrheliometer of Pouillet (Poggendorff's Annalen, xlv.), or the actinometer of Herschel (1825), which instruments replace the earlier contrivances of earlier days, such as Leslie's photometer (1797), and De Saussure's helio-thermometer (1787). The only self-recording apparatus that indicates the power of the direct rays of the sun at present in use is the so-called black-bulb-in-vacuum or solar-radiation thermometer of Negretti and Zambra. Observations with Pouillet's pyrheliometer show that the absorption of solar heat by the atmosphere follows sensibly the same law as the absorption of solar light, and amounts for the temperate zone to from 20 to 40 per cent. when the rays penetrate vertically downward. According to the investigations of Melloni, Tyndall, Magnus, and others, aqueous vapor is almost opaque to the invisible heat rays belonging to the red end of the spectrum, and accordingly an increase in the absorption of the direct solar rays occurs where an increased amount of moisture is present in the air. The absorption of solar heat by the material composing the earth's surface varies of course with every change in the constitution or molecular condition of the latter. Dry and sandy or rocky soils become heated to a higher temperature than the moister portions of the earth, while the ocean experiences the least variation of temperature. But perhaps the most important property of the earth's surface consists in this, that the rays which are not absorbed by it, and which are consequently radiated back through the atmosphere, have been degraded to the red end of the spectrum; these are therefore very largely absorbed by the aqueous vapor in the lowest portions of the atmosphere, from 40 to 90 per cent., according to the dryness of the air, being retained within one or two miles of the earth's surface. As a consequence of this absorption, the temperature of the air at the surface rises most rapidly during the day at places covered by a layer of clear moist air, even though such layer be at a considerable altitude above the station, without reaching down to it; and on the other hand, the temperature diminishes most rapidly at night when a clear atmosphere, holding but little moisture, exists over the station. The conduction and convection into the interior of the earth and ocean of the solar heat that falls upon its surface, produces such a storing up of heat as to sensibly ameliorate the sudden changes that would otherwise occur, and to delay the periodical daily and annual maxima and minima of atmospheric temperature. The temperature of the soil has been measured by means of thermometers whose bulbs are, as was first suggested by Quetelet, permanently imbedded therein; and the general laws governing the distribution of temperature in the interior of the earth were mathematically investigated by Fourier (1812) and Poisson (1835). The range of the variations of temperature diminishes rapidly as we descend into the soil, forming an inverse geometrical series when the depths form an arithmetical series; again, the durations of corresponding periodical changes in temperature at and below the surface of the ground increase at any depth in proportion to the square root of the durations of the surface periods. Daily variations of temperature are perceptible at a
depth of 3 ft., while annual variations are barely observable at a depth of 80 ft. The effect of the sun's heat upon the water of the ocean differs in some important respects from its effect on the continents: first, in that a large percentage of heat is rendered latent in evaporating the surface water of the ocean; secondly, in that the specific heat is much larger for water than for dry earth; and finally, in that the mobility of the water permits of a very extensive system of convection. According to the observations of Lenz (1829), Carpenter (1870), Thomson (1874), &c., the average temperature of the ocean at depths greater than 500 ft. is that of the maximum density of water at the pressure to which it is subjected. The temperature of a layer a few inches in thickness on the immediate surface of the water can, when the ocean is very still, be raised as high as 90° E.; but in the general disturbed condition of the water its surface temperature is much below that of the adjacent strata of the air. As a secondary effect of the influence of the ocean, must be noted the fact that the heat rendered latent in the evaporation of its surface water in great part returns to the atmosphere when that vapor is condensed to cloud and rain.—Having thus indicated the original sources of atmospheric temperature, we come to the consideration of that subject itself. In order that the temperatures measured in different portions of the world may be comparable among themselves, it is necessary that uniformity should be secured in the exposure of the thermometer to such influences as can affect its indications. As a general rule, in ascertaining the temperature of the lowest stratum of air, the thermometer should be elevated not less than 5 nor more than 50 ft. above the earth's surface, and should be surrounded on all sides, at a distance of from 1 to 5 ft., by a light double latticework, or equivalent structure, which can itself rapidly follow the varying temperature of the air, and prevent all radiation of heat except that which takes place between the thermometer and the interior of the latticework. But such a thermometer cage is scarcely practicable in the investigations of the temperature of the upper strata, so far as they can be reached by aeronauts, and numerous but unsatisfactory studies have been made into the relations between the indications of protected and unprotected thermometers. Some knowledge as to the temperature of the upper strata is given by the study of the refraction by the atmosphere of the rays of light which reach us from the celestial bodies. The most important features of atmospheric temperature are its variation with the altitude, its diurnal variation, its annual variation, and its geographical distribution. On the three latter points the mass of information can best be presented by graphic methods, as in the accompanying diagrams. But the irregularities of the temperatures at various altitudes may be better seen by the study of the following table:

### The Decrease of Temperature with Increase of Elevation

Elevation has apparently a diurnal and an annual change, and 30 ascensions in 1868 showed that it may very probably often during the night be reversed into an increase instead of decrease, at least for the lowest 2,000 ft. Above the clouds the temperature decreases very steadily. As an average of all of his midday ascensions, Glashier says that the diminution in the first 1,000 ft. was 4° with a cloudy sky, and 6° with a clear sky. In an ascent made on April 6, 1864, remarkable variations were met with, such that at 10,000 ft. the thermometer was registered to the same as on the earth's surface, but on this occasion clouds and fogs alternated up to the highest point attained by the balloon.—Diagram No. I. shows the diurnal variations of temperature for January and July, as deduced from observations continued through several years at stations in different geographical positions. In this table the average daily temperature of the month is assumed as the zero line. The annual variations for a few representative stations are shown graphically in diagram No. II., where even the minor features of the yearly changes are developed by the use of Dove's five-day means. It will be noted that the maximum temperature occurs at Madras at the time of the solstice, while at stations further north it occurs two to five weeks later. Diagrams No. III. and IV. give the average distribution of mean temperatures over the surface of the earth as shown by means of the isothermal lines for January and July respectively, as published
comparison of the isothermals for January and July shows at a glance the results of the combined influence of the solar altitude, the distribution of continents, plateaus, oceans, &c. The more detailed analysis and comparison of these temperatures belongs to the subject of climatology. So far as our observations extend, they show that the annual mean temperatures of the points having the same latitude are about 2° higher in the northern than in the southern hemisphere. The average temperature of the whole earth, according to Dove, is greater in July than in January by about 8° F., although in July the earth is further from the sun than in January, in the ratio of 99 to 90. Besides the preceding normal and periodical fluctuations of temperature, as deduced from the average of many observations, the temperature of the air is subject to large non-periodic variations, which disturbances, properly so called, are considered in connection with Stroms, under that title. The more important of these non-periodic variations accompany the areas of moist and dry air, as these successively flow over the earth's surface. These disturbances in the periodical variation of temperature have their origin in terrestrial influences, and are the secondary reaction of the sun's rays themselves.—3. Winds and Currents. If we neglect the slight amount of heat received from other sources, we may in general say that the winds are due to the combined influences of the rotation of the earth on its axis and the disturbances of the air, caused either by the introduction and subsequent condensation of its vapor, or simply by the warming of the lower strata of the atmosphere by the sun. The movement of the air is therefore a question of mechanics, capable of solution in just so far as mathematical analysis is able to fully take into account the combined influence of these primary forces, and the laws of pneumatics, friction, &c. This subject has been inductively investigated by Coffin, Buchan, Muhry, and Hann. The observations of the lower strata of the air are best obtained, as regards the directions of movement, by the self-recording wind vane, and as regards their velocity, by the self-recording anemometers. Apparatus by which these two anemometric elements are recorded continuously has in some form or other been adopted during the past few years by the government observers at a large number of stations throughout the world. The measurement of the pressure exerted against a flat surface by the wind is sometimes substituted for the direct measurement of the wind's velocity; but these two elements are only with difficulty and approximately to be compared between themselves. When observers have no means of measuring force or velocity, an empirical scale is adopted, two forms of which are in common use, that of Admiral Beaufort and that of the Smithsonian institution; these are given in the following table. Owing to the great differences in the estimates.
Diagram II. — Annual Variations of Temperature

Diagram IV. — Isotherms or Lines of Equal Temperature for July.
of wind force, it is difficult to convert these empirical scales into actual wind velocities, and they should be discarded whenever a good anemometer is available.

The movements of the upper currents of the atmosphere have been observed by means of the clouds, balloons, the transfer of volcanic ashes, and the occasional luminous trains that are left in the wake of bright meteors. These latter, being from 10 to 100 m. above the earth's surface, have given us the only knowledge we have attained with respect to the currents at so great an elevation. With regard to the ascending and descending currents of air, no satisfactory method of observation has yet been put into execution, though such seems practicable by an aeronaut. So far as our present information justifies an opinion, it seems probable that at an altitude of above 10 m. the atmospheric currents are subject to variations as large, though perhaps not as sudden, as the winds at the surface. In the lower portion of the atmosphere it is not uncommon to find two or three currents of air, from as many different directions, superimposed upon each other. (See STORMS.)—The general phenomena of the winds at the surface of the earth may be considered in reference to their diurnal and annual variations, and their geographical distribution. The daily period in the strength and velocity of the wind is due in great part to the unequal heating of the different portions of the land, and especially to the over-heating of the land as compared with the sea. This period is most strikingly manifested at the stations on the immediate coasts of continents, and on the borders between mountainous countries and plains. In the latter case the elevated regions of the earth are cooled by nightly radiation, and the cold layers of dry air in contact therewith subsequently flow down and slip under the warmer

![Diagram V.—Diurnal Change in the Direction of the Wind at Wallingford, Conn.](image-url)
In 1871, in this figure the arrows show the direction toward which the wind moves; the respective monthly lines show by the changes in their directions, at every point from feather to barb, the changes of the wind from hour to hour. It will be seen, in fact, that in May the early morning winds are northerly (land breezes), while the evening winds are southerly (sea breezes). A daily period in the force with which the wind blows is as conspicuous as the periodicity in its direction. This is well exemplified in diagram VI., from Loomis, showing the average pressure of the wind in pounds per square foot for each hour, derived from the observations of Bache at Philadelphia.—The annual variations of the wind may be traced back to the same ultimate cause, namely, the varying influence of the unequally heated portions of the continents and oceans. The most remarkable annual variations in the winds are those known as monsoons, in the Indian ocean. The most remarkable permanent or nearly permanent winds are the trade

winds, which flow from the northeast and southeast, in the northern and southern hemispheres respectively, toward the equator, and include between them a narrow belt of equatorial calms. The latter has a breadth of a few degrees only, and varies its position with the seasons, lying somewhat further to the north of its mean position in July, and to the south in January. On account of the intimate relation between the direction of the wind and the barometric pressure, it is best to represent these two meteorological elements on one map; and accordingly on the accompanying charts, Nos. VII. and VIII. (compiled from those published by the British admiralty in 1872), are shown by arrows flying with the wind, the prevailing winds for the months of July and January, over the entire globe; regions of prevailing calms are designated by shaded circles. The comparison of these charts will show more clearly than words the great changes which take place in the movements of the air during the year. The principal regions of calms and light variable winds, besides the equatorial belt already mentioned, are those belts about 10° broad, lying N. and S. of the trade wind regions, in the respective hemispheres. Coffin (1853) has moreover shown that N. of the belt of calms in the Atlantic the winds both of Europe and America show comparatively slight but decided indications of monsoon features, due to the over-heating of the land in summer and its cooling in winter. Similar phenomena are observed in reference to the Sahara of northern Africa, and to the continent of Australia. Of the non-periodic variations of wind, the most important are those attending storms. Dove has shown that, at any station in the northern temperate zone, the wind voers more frequently than it backs; that is to say, the successive wind changes are more frequently in the order S., W., N., &c., than they are in the reverse order, S., E., N., &c. But this interesting law may be considered as a simple consequence of the position of the stations in relation to the paths generally pursued by storm centres. Redfield (1831-57) was the first to prove that in all extensive severe storms there is always present a system of surface winds revolving about and blowing in toward a storm centre, which latter has a progressive motion along the surface of the earth. At a short distance above the earth’s surface there is a system of outward-moving spiral currents immediately above the lower inward-moving winds. The independent investigations of Espy (1837), Reid, Piddington, Ley, and others, have abundantly confirmed the correctness of Redfield’s conclusions; and the studies of later writers have shown that such a system of winds is characteristic of severe storms throughout the world. (See Hurricane; and Storms.) The relation between the wind and temperature is graphically represented by the thermal wind rose, which gives for each direction of the wind the average temperature prevailing after eliminating the effects of the daily and annual changes and the lesser local peculiarities. The following table presents a few of the stations for which sufficiently long periods of observation are available to render the average results trustworthy:

The connection between the direction of the wind and the position of the moon in its orbit has been investigated by Schubler and Eisenlohr for stations in Germany, and the results, as shown in the following table by Schubler, would indicate that N. and E. winds are more frequent at the time of the last quarter of the moon, and that S. and W. winds prevail at the second octant:

—4. The *Aequora Vapors*, whose presence in the atmosphere is of the highest importance in a meteorological point of view, as well as in reference to animal and vegetable life, may here be considered as having its ultimate origin in the ocean, whence it is drawn by surface evaporation under the influence of solar heat. Its subsequent diffusion throughout the atmosphere is in a slight degree due to Dalton’s principle of the diffusion of gases, but principally to its convection by the winds; its deposition, whether in the form of clouds or rain, is the result of the subsequent cooling of the moist air. Of the rain which falls upon the land, a large portion is again evaporated, and thus returned to the atmosphere, and ultimately to the ocean. The quantity of moisture in the air is determined for meteorological purposes by means of observations with either the hair hygrometer of De Saussure, the wet and dry bulb thermometers of August, or the dew-point instruments of Daniell, Regnault, Bache, and others. (See Hygrometer.) Measurements of evaporation have such a peculiarly local significance that it has been difficult to ascertain any practicable means of making these comparable with each other; but it may be said
with considerable certainty that evaporation is
two or three times greater in sunshine than in
shade; is four or five times greater in hot sum-
er days than in cold winter days; is greater

and on the other hand, by leaving the remaining
air dryer, allows a more perfect radiation
into space of the terrestrial heat, thereby
increasing the diurnal variations of tempera-
ture. The diurnal variation in the
expansive pressure exerted by the
vapor is illustrated by diagram IX.,
showing the results of observations
made at Vienna. The annual varia-
tion in vapor tension is given for
the same station in the following
diagram, No. X. By the relative
humidity is meant the absolute hu-
midity expressed as a fraction of the
total quantity of moisture that the
air would contain if perfectly satura-
ted at its observed temperature. As
to its diurnal variation, the relative
humidity is least in the hottest portion of the
afternoon, and greatest shortly before sunrise,
as shown in diagram XI.; similarly, as to its
annual variation, it is least in the summer
months and greatest in the winter, as shown
by comparing the curves for January and July
in the same diagram, or more fully by the an-
nual curve (R. H.) given in diagram X., where

in windy weather in proportion to the strength
of the wind; is greater in dry than in moist
weather; greater from marshes and forests
than from fields of melting snow; greater
from the latter than from the surface of the
ocean; and in general greater in the equatorial
than in the temperate regions. The aqueous
vapor in the atmosphere may be considered
from several points of view, namely: as to the pressure it
exerts in maintaining barome-
tric equilibrium; or as to its
absolute quantity; or, again,
as to its relative quantity as

compared with the amount re-
quired to saturate the atmos-
phere. The condensation of a portion of the
vapor into cloud or rain, on the one hand,
diminishes the barometric pressure, thereby
giving rise to local areas of low barometer,
It is true that in the interior of North America and of Asia the air at the surface is rarely if ever completely saturated; but on the other hand, the monthly and annual averages show that a very large amount of aqueous vapor is always present even in those regions, notwithstanding their comparative dryness. The distribution of moisture in reference to altitude above the sea was for a long time supposed to follow the law suggested by Dalton (1806), namely, that it was expanded throughout the atmosphere precisely as if constituting an independent vaporous atmosphere within the gaseous one; but the later researches of Regnault, Bessel, Strachey (1861), and Hann (1874) have shown the fallacy of this theory.

According to Hann, the pressure diminishes as we ascend more rapidly than it should according to Dalton's law, and the weight of the vapor existing in a vertical column above a given place is only 0.22 of what his law would indicate; five tenths of the aqueous vapor is within 6,500 ft. of the surface of the sea, and the strata under 20,000 ft. in altitude contain nine tenths of the vapor in the entire atmosphere. The ratio between the quantity of vapor at a given height and that at the surface is shown in the following table, as deduced by Hann from balloon and mountain observations:

On the other hand, the irregularities of the distribution of vapor are such that the observations made in England in balloons show that layers of moist and dry air may alternate with each other. In the United States, and generally in continental situations, it is probable that such alternations only attend storms. The relation between moisture and the direction of the wind is expressed graphically by the so-called hygrometric wind rose, which gives for each direction of the wind the average force of vapor and relative humidity. The following table shows these relations for some of the few stations for which the computations have been made:

The relative dampness of the easterly winds and the dryness of the westerly winds is well shown by this table for Europe. We also see that the fact that the summer winds are dryer than the winter is due to their increased temperature and capacity for vapor, and not to any diminution in the quantity of vapor held by them, since the latter is in summer larger than in winter.

---

This is apparent under the forms of cloud, fog, dew, and rain, and their various modifications, and produces a local diminution in the barometric pressure. The quantity of dew admits but very rarely of precise measurement, the most satisfactory series of experiments having been made by Dr. W. C. Wells in London. (For many details concerning it, see Dew, and Fross.) However important an abundant dew may be to the husbandman, it can scarcely be considered by the meteorologist as other than a local and temporary-phenomenon, of minor importance in the general economy of the atmosphere. The formation of fog is but little more important in this connection. (See Fogg.)

Of more importance to all classes must be esteemed the formation of clouds and rain. (See Clouds, and Rain.) Clouds, according to the commonly received classification of Howard (1802), are divided into the cirrus, stratus, cumulus, and nimbus, for which latter Poey (1872) has proposed to substitute the pallium or sheet cloud. Howard intended by the term nimbus to designate those clouds from which rain was falling; but it does not appear certain that rain may not occasionally fall from either the stratus, the cumulus, or the pallium, or from the numerous combinations of these typical forms. The presence of clouds and the phenomena displayed by them are valuable to the meteorological observer, both as affording him an indication of the direction of the upper currents of air, and as giving some clue to the moisture and temperature there prevailing. For the present we have principally to do only with the average percentage of cloudiness, and its influence upon the temperature. A diurnal periodicity, showing two maxima and two minima in the percentage of cloudy sky, will be perceived by the most cursory observer; the hours at which these occur vary with the kind of cloud; for the cumulus they are, maximum at 3 P. M., minimum at 5 P. M.; for the stratus, maximum at 6 A. M., minimum at 3 P. M. In mountainous countries it is easy to trace the direct dependence of this periodicity upon the heating of the soil during the day time and the cooling of the air by radiation during the night time; but the daily period is also distinctly pronounced within the tropics, and is clearly seen whenever a station in the temperate zone is in the interior of the continent within the range of an area of relatively dry air. The total percentage of all kinds of clouds is shown for two European stations in the following table for January and July:
Diurnal Variation in Cloudiness.

The connection between the lunar phases and the cloudiness has been already spoken of. The influence of cloudiness in protecting the earth's surface against the direct rays of the sun, and against nightly radiation from the earth, has been investigated for a few stations only. According to Weilenmann (1874), the atmosphere, when the sky is clear, protects the earth against radiation by an amount equal to one third of the protection afforded by a cloudy sky, whence the latter may be concluded to allow on the average scarcely 15 per cent. of the solar heat to reach the earth's surface. The connection between cloudiness and barometric pressure has not yet been studied with the care it deserves; but it is certain that a low barometer corresponds to an increased cloudiness, and an important portion of the daily variation in the barometric pressure depends upon the formation of fog at night and of cumulus clouds by day. The rainfall may be considered as the completion of the process of the formation of clouds, although probably the majority of clouds are dissipated without producing rain. The larger part of the rainfall is probably deposited by uprising currents of air, and therefore it has its daily and annual periods. The formation of snow is apparently more directly dependent upon nocturnal radiation of heat. The measurement of rainfall by means of the simple rain gauge needs to be made under circumstances of great uniformity, if for different stations we would attain results comparable with each other. The most minute investigations of the laws governing rainfall have been made by Symons, and published since 1866, in his annual volumes of "British Rainfall." According to these results, which are abundantly confirmed by other measures taken throughout the world, the quantity of rain received by a gauge diminishes in an irregular manner with the height of the gauge above the earth's surface. The diminution is apparently to be attributed principally to the greater velocity of the wind at the higher station, and amounts to 10 per cent. of the whole rainfall for an elevation of 20 ft., and in one exceptional case, at the height of 50 ft., to 40 per cent. of the rainfall at the surface. The study of the diurnal period of the precipitation (including rain and snow) has as yet led to only an imperfect result; but it is believed that as a general rule, in the temperate zones, a maximum occurs in the afternoon in the summer, but before sunrise in the winter months. The annual variation in rainfall depends almost exclusively upon the relation between the winds and the geographical position and topographical details of the country. On the W. coast of North America and of Europe the greater part of the annual rainfall occurs in winter, but in the interior of Europe and on the E. coast of the United States in summer. The geographical distribution of the snow and rainfall over the world can be properly presented only by means of a very large and detailed chart; its

**An annual periodicity in the cloudiness is also observed (see the following table), having its maximum in the winter time throughout the temperate zones, while within the polar circle the maximum cloudiness may be placed in the late summer and fall.**

As regards the geographical distribution of cloudiness, it may be remarked briefly that the annual averages show a minimum cloudiness in the regions of the trade winds and in the interior of continents, and a maximum in mountainous districts, the polar regions, and on the western coasts of the continents. The relation between the direction of the wind and the average degree of cloudiness is known to all, and is rendered apparent by the following table:

general distribution over the United States is shown by the accompanying map (XII), compiled by Schott for the Smithsonian institution, from all the data available in 1872. The heaviest rainfall occurs in those countries in which warm moist monsoon winds blow from the seacoast up over rapidly rising hills. Thus the annual rainfall on the Cossyah hills, facing the bay of Bengal, is 600 inches, but 20 m. further inland it is reduced to 200 inches, and at 30 m. to 100. The connection between rainfall and the direction of the wind presents therefore an apparent discrepancy in various parts of the world, even for stations on the same parallel of latitude, according as the winds ascend in their course from the ocean level to hilltops, or descend from the mountains and plateaus to the lowlands. The percentage of rainy and not rainy winds is given for London in the following table, which shows that 69 per cent. of the days when S. W. winds prevail are rainy, while only 33 per cent. of the E. and N. E. winds bring snow or rain:

6. Barometric Pressure. It is only when we come to study the pressure of the atmosphere, as shown by the barometer, that we arrive at a connected intelligible view of the peculiarities of weather and climate. In fact it is evident that no portion of the atmosphere can be moved from one region to another, except under the influence of a pressure applied in the direction of its motion; such movement is simply an effort to re-establish a disturbed statical equilibrium. The laws of mechanics show that relatively to the earth's surface the air would remain quiescent if the sun were absent; but the density of the atmosphere is disturbed by the solar heat, by the variable quantity of aqueous vapor rising from the oceans and continents, and by the local condensation of this vapor into cloud and rain. In this way temporary abnormal inequalities in the distribution of barometric pressure are produced, which give rise to the winds, and afford the meteorologist that connecting link which enables him to unite the whole circle of atmospheric phenomena into a harmonious system. (See Barometer.) The height of the barometric column is found to vary at the same station in regular diurnal and annual changes, and also in a non-periodic manner; on moving the instrument to other places, its height is found to vary with the geographical position, and in an especially remarkable degree with every change of altitude. The latter class of changes have been the subject of numerous profound investigations, having for their ultimate object both the utilization of the barometer for hypsometric purposes, and the solution of the inverse problem, the reduction of actual barometrical readings to the sea level. The solutions of both these problems can as yet be satisfactorily effected only in respect to annual means; but within allowable limits of error approximate methods may be applied to monthly means and

The dotted line is for Nertshank, Asia continental station; the full line, for Plymouth, Eng. maritime station.

Diagram XII.—Diurnal Variations in the Barometer.

to individual observations, when the altitude of the station does not exceed 2,000 ft. The
systematic variations in the barometric pressure can be best shown graphically, and it will suffice to present only a few typical cases. The existence of a perceptible lunar tide in the atmosphere is now no longer considered probable, and the important periodic changes all depend upon the sun. The diurnal changes, as shown in diagram XIII. for Nertchinsk, Siberia, and Plymouth, England, illustrate respectively the continental and maritime stations. The effect of elevation above the surrounding country (not merely above sea level) is seen in the contrasts between the diurnal changes at Geneva (altitude 1,335 ft.) and at the summit of Mt. St. Bernard (8,114 ft.), as shown in diagram XIV., both for January and July. At the sea level, two maxima and two minima of pressure occur during each 24 hours; the maxima between 9 and 11 A.M. and between 9 and 11 P.M., the minima between 3 and 5 P.M. and between 2 and 5 A.M., respectively. The annual barometric changes are shown in diagram XV., as given by Lorenz and Rothe (1874) for typical stations, whence the great influence of geographical position is easily seen. A clearer perception of the important part played by aqueous vapor will be obtained if from the whole atmospheric pressure shown in diagrams XIII., XIV., and XV. we subtract that portion due to aqueous vapor, as shown in diagrams IX. and X.; the remainder is technically known as the pressure of the dry air, or the gaseous atmosphere. It is found that the gaseous and the vaporous components have each a single diurnal and annual fluctuation, and that it is the combination of these that produces the irregular and even double fluctuations in the total pressure shown in the preceding diagrams. A general view of the annual barometric changes, and a more complete insight into the relation between pressure, wind, and weather, are obtained by the comparison of a series of charts, such as VII. and VIII., which show for the respective months the average distribution of the pressure of the atmosphere over the surface of the globe. The variations of barometric pressure with the latitude were first defi-
The variations which occur on the same parallel of latitude, and especially the seasonal differences between the pressures over the land and the ocean, were first elaborated by Buchan (1868). The charts VII. and VIII. are compiled from the latest results published by Buchan and by the admiralty office in London, and must be considered as representing very nearly the actual distribution of barometric pressure over the globe, as reduced to a uniform sea level. The irregular or non-periodic variations of the pressure are intimately connected with the disturbances or storms which sweep over the earth. (See Hurricane, and Storms.) The regions of greatest average irregular barometric variations coincide in general with the regions of most decided alternations between clear, cold, dry weather, and cloudy, warm, moist, or rainy weather. In analyzing this connection between pressure and weather, we will only mention the relation between the barometer and the winds and rain. The general connection between the changes of pressure at any place and the winds is shown in the following table, which gives the average reading of the barometer during the prevalence of the respective winds for a few typical stations in the northern hemisphere; in these cases, as for the entire globe, the pressure is greatest for cold or dry winds, and least for warm or moist winds, which law obtains in both the winter and summer seasons:

The relation between atmospheric pressure and rainfall depends upon the direction of the accompanying wind; but if, as in the following table, each wind direction be treated by itself, it will be seen that during rain and snow the pressure is usually below the average for that wind, and is falling still lower for southerly winds and increasing rain, but is rising for northerly winds and clearing weather:

Barometric Variations preceding and following Rain.

The connection between the temperature, pressure, wind, and weather may be briefly indicated in the so-called weather rose, examples of which are presented for central Europe and for a portion of the United States in diagrams XVI. and XVII.—We here terminate our presentation of some of the more interesting relations between those meteorological phenomena which admit of exact observation, and which form a safe basis for further philosophical investi-

Diagram XVI.—Weather Rose for Central Europe.
attempts to predict the weather, and especially storms, which are now daily made by the meteorological offices of numerous civilized nations would of themselves seem to imply the existence of a deductive science more or less developed. This however is not necessarily the

"On the Motions of Fluids and Solids, relative to the "Earth's Surface" (Nashville, 1854, and New York, 1860). In this treatise the motions and figure of the atmosphere are first treated of, on the hypothesis that no resistance is offered by obstacles or by friction upon the earth's surface; in a subsequent section the influence of such resistance is considered, on the hypothesis that a uniform coefficient of friction obtains over the whole earth's surface. Mr. Ferrel thus deduces the necessary existence of two belts of high barometric pressure, extending entirely around the globe between the tropics and the parallels of 30° N. and S. respectively, and of a belt of low pressure at the equator, as well as regions of low barometer within the arctic and antarctic circles; belts of calms near the equator, the tropics, and the polar circles are also deduced. The continents and oceans offer very unequal frictional resistances, which causes the equatorial belt of calms to lie on the average a little north of the true equator in the Atlantic and Indian oceans, but nearly on the equator in the Pacific ocean. Similarly, it can be shown that to the irregular distribution of the friction of the continents is partially due the breaking up of all these belts into segments lying respectively over the ocean and the continents. In general the motion of the earth's atmosphere is a consequence of the unequal heating by the sun of the equatorial and polar regions; the subsequent effort of nature to establish statical equilibrium relative to the earth's surface is that which gives rise to the phenomena of the winds. The unequal heating of the continents and oceans, due to their unequal specific heats and radiating power, and to the annual vibration of the sun between the tropics, is the principal cause of the breaking up of the belts of temperature, pressure, and winds into continental and oceanic areas. But whatever induces a local or general change in the density of the air disturbs its equilibrium and necessitates its motion; and the disturbing power next in importance to the solar heat is the diffusion of aqueous vapor, the density of which is only six tenths of that of dry air at the same pressure and temperature. It thus happens that the combined effect of friction, temperature, and moisture gives rise to the variable distribution of barometric pressure exhibited in the charts VII. and VIII., which show areas of high barometer existing in winter over the continents, but in summer over the ocean, and over the eastern half of each ocean, rather than over its central portions. The general distribution of barometric pressure having been thus deduced by Mr. Ferrel, he then considers the local disturbances known as cyclones, tornadoes, &c., all the phenomena of which are deducible from his initial mechanical formulas (see "Bulletin of the Philosophical Society of Washington," June, 1874, and the "American Journal of Science," November, 1874), if we supplement these by the researches of Hirn, Peslin, and Rey.
These latter have applied to the phenomena of the atmosphere, and especially to its vertical motions, those laws of thermodynamics which were first fully insisted on by Esdy in "The Philosophy of Storms" (1841), but which required the accurate experiments of Regnault and the analysis of Clausius, Thomson, and others, to make them available quantitatively, as well as qualitatively, for meteorological purposes. The above mentioned authors have shown the connection that must exist between the expansion of uprising moist air (whether it be pushed by winds up over elevated regions, or ascend on a hot day in consequence of local rarefaction), and the formation of clouds and rain, deducing thereby, with great minuteness, many of the details of the origin, growth, path, and decay of storms. Finally, the phenomena of radiation and absorption of heat, though as yet only partially deducible from correct physical theories of the constitution of gases, may still be looked upon as well determined experimentally by the observations of Tyndall and others, as far as regards the constituents of the atmosphere, and form the basis of the law of change by which we are able to deduce the general laws of the periodic and non-periodic changes of temperature and moisture. We are thus in a position to reduce all meteorological phenomena to the three principles involved in general mechanics, thermodynamics, and molecular physics; and it may be confidently expected that the increasing powers of mathematical analysis will ere long enable us to rear upon these a superstructure of deductive meteorology, whose application to the explanation and even the prediction of the weather will be limited only by the extent and accuracy of our observations.

METHODISM, a form of church life and polity which originated in England during the 18th century. I. EARLY HISTORY AND PRINCIPLES. The moral and religious condition of England at the beginning of the 18th century was most deplorable. The court was dissolute; the standard of taste was low; the prevalence of skepticism was alarming; the church, both established and dissenting, had lapsed into a state of lifeless formalism; the masses of the people had sunk into incredible vice and brutality. In the year 1729 John Wesley, a fellow of Lincoln college, Oxford, became convinced of the necessity of a deeper spiritual life. With his brother Charles, likewise a student of Oxford, and a few other associates, he organized a meeting for their mutual moral improvement. The band soon began to manifest increased religious zeal by visiting almshouses and prisons, by instructing the children of the poor, and by a strict and conscientious observance of all the ordinances of the church. They were soon joined by others, among them Mr. Hervey and Mr. George Whitefield of Pembroke college, till at the end of six years they numbered 14 or 15 persons. The rigid exactness of their lives attracted general attention among their fellows; they were objects of ridicule and contempt, and received various designations, but the term "Methodists" was applied to them by a student of Christchurch college, on account of their methodical mode of life and work. On the departure of the brothers Wesley to Georgia in 1735, the band was dissolved, but the new religious life that had there been enkindled manifested itself in the more zealous ministrations of the members of the "Godly Club." After his return, Wesley began to preach in London and elsewhere with great fervor. His sole object was to bring back the church to a pure and holy life, and to save the degraded and neglected. For the same object Whitefield and others had already labored earnestly during the absence of the Wesleys in Georgia. These reformers were at first received with coldness by the public, and their labors were regarded with suspicion or hostility. Wesley was at length debarred admission to the pulpits. In the early part of 1739, Whitefield had set them the example of open-air preaching at Kingswood, near Bristol, where he had addressed an immense crowd of colliers. Though at first disapproving of Whitefield's attempt, after a brief hesitation John Wesley as well as his brother Charles followed this example. Being denied admission to the churches by the clergy, they were compelled to continue their preaching in private houses, barns, market places, and the open fields, as opportunity was given. Thousands flocked to their ministry, and multitudes were converted. Wesley and his coadjutors were stubbornly opposed by the dignitaries of the establishment, who were strongly in condemnation of this violation of ecclesiastical order. Sometimes the mob was stirred up to revile and assault them; sometimes the power of the law was invoked against them as disturbers of the peace. The converts made by their preaching were either despised or utterly neglected by the church, and hence Wesley, at their own request, formed them into societies for mutual edification and improvement, called "the United Societies." Wesley's own account of their origin is as follows: "In the latter end of the year 1739 eight or ten persons came to me in London, who appeared to be deeply convinced of sin, and earnestly groaning for redemption. They desired (as did some two or three more the next day) that I would spend some time with them in prayer, and advise them how to flee from the wrath to come, which they saw continually hanging over their heads. That we might have more time for this great work, I appointed a day when they might all come together; which from thenceforward they did every week, viz., on Thursday in the evening. To these, and as many as desired to join with them (for their number increased daily), I gave those advices from time to time as I judged most needful for them;
and we always concluded our meetings with prayer suitable to their several necessities. This was the rise of the united society, first in London, and then in other places. Such a society is no other than a company of men having the form and seeking the power of godliness, united in order to pray together, to receive the word of exhortation, and to watch over one another in love, that they may help each other to work out their salvation. The mass of those who had been converted were from the poor and uneducated classes. For the government of these societies a few simple rules were proposed by the Wesleys, which, with slight exceptions, are still recognized as the "General Rules" by all branches of the Methodist church. The sole condition of membership in these societies was "a desire to flee from the wrath to come and to be saved from sin." But this desire will be shown by its fruits, leading the man to avoid evil and to do good. Hence these rules forbade in the members of these societies the evils then most generally practised, "such as profane swearing, Sabbath breaking, drunkenness, buying or selling spirituous liquors, or drinking them except in cases of extreme necessity; fighting, quarrelling, brother going to law with brother, returning evil for evil or railing for railing; the using of many words in buying and selling; the buying or selling of uncustomed goods; the giving or taking things on usury, i.e., unlawful interest; uncharitable or unprofitable conversation, particularly speaking evil of magistrates or of ministers; doing to others as we would not they should do unto us; doing what we know is not for the glory of God, as the putting on of gold and costly apparel; the taking of such diversions as cannot be used in the name of the Lord Jesus; the singing those songs or reading those books which do not tend to the knowledge or love of God; softness, and needless self-indulgence; laying up treasures upon earth; borrowing without probability of paying, or taking up goods without probability of paying for them." But it was "expected that all continuing in these societies should continue to evidence their desire of salvation, secondly, by doing good; by being in every kind merciful after their power; as they have opportunity, doing good of every possible sort, and as far as possible to all men; by feeding the hungry and clothing the naked; by helping or visiting them that are sick or in prison; by instructing, reproofing, and exhorting; by doing good especially to them that are of the household of faith, or grieving to be so; employing them preferably to others, buying one of another, helping each other in business, &e., and so much the more because the world will love its own, and them only; by diligence and frugality; by self-denial and by submission to bear the reproach of Christ; by attendance upon the ordinances of God, such as public worship, the ministry of the word, the supper of the Lord, family and private prayer, searching the Scriptures, and fasting and abstinence."

These rules were declared to be taught in God's Word, and that they are written on every truly awakened heart. If any violate these rules, they are to be admonished and borne with for a season; but if they persist, then they are to be excommunicated. For the accommodation of these societies chapels had been provided at London and Bristol. During 1740-41 Wesley and his co-workers were preaching and founding societies in Yorkshire, Derbyshire, Leicestershire, and Wales, while Whitefield had made his second voyage to America, and by his wonderful eloquence had aroused the religious consciousness of the people from Maine to Georgia. On the return of Whitefield the differences between him and Wesley on doctrinal points caused their separation, and Whitefield organized the Calvinistic Methodists in 1741. By the labors of Whitefield, Methodism was introduced into Scotland and Wales, and, aided by the munificence of the countess of Huntingdon, chapels were provided and a college for preachers was founded. Calvinistic Methodism had many remarkable adherents, who were instrumental in the conversion of multitudes. Next to Whitefield in labors and success was Howell Harris, the apostle of Methodism in Wales; and not less in labors were Romaine, Madan, Venn, Berbridge, and others. In 1744 Whitefield made his third voyage to America, repeating the labors of former visits, and preaching with wonderful effect in the Bermudas in 1748. On his return to Europe in June, 1748, he visited Scotland, and also preached to immense congregations in England. In 1747 Thomas Williams, a lay preacher from England, had formed a society in Dublin. In the same year the Wesleys visited Ireland, and great success attended their ministry, though bitter opposition was experienced from the Roman Catholic population. Among the converts from Catholicism in 1749 was Thomas Walsh, who has been styled the apostle of Methodism to the Irish. In 1744 Wesley had invited several clergymen of the establishment and his lay assistants to meet him in London, to give "their advice respecting the best method of carrying on the work of God." Thereafter these "conferences" were held annually, and were occasions of revising the work, laying plans for the ensuing year, and discussing questions of doctrine and polity. In the midst of his severe labors Wesley wrote in defence of the system which he had inaugurated, and devised means for the education of his preachers and the improvement of his churches. In 1757 he was joined by John Fletcher, a Swiss by birth, who had been ordained a priest in the established church. In him Wesley found an earnest defender and a powerful apologist for his doctrinal views. During the progress of this wonderful revival work, the strong opposition of the clergy of the establishment continued. Individual examples of sympathy and aid to the itinerants were found, but in many in-
stances the converts, and even Mr. Wesley and some of his clerical fellow-workers, were repelled from the eucharist. Under these circumstances it was felt by many that these societies should receive the sacraments at the hands of their own preachers, and some had ventured to administer them. The conference of 1755 was greatly agitated with this question, and the kindred one of separation from the established church was openly disapproved; but after a protracted debate, it was decided to be inexpedient to form a separate church. Since the first voyage of Wesley to America in 1735, the Moravians, whom he then met, had by the simplicity and purity of their lives exerted a powerful influence on the Methodist movement. They had societies in London and elsewhere, but their numbers were limited, and they lacked that compact organization necessary for permanent success. Between 1750 and 1760 Ingham, assisted by Moravian helpers, founded more than 80 societies in Yorkshire and the neighboring counties. These were in close affiliation with the Arminian and Calvinistic societies, but had their separate conferences. In 1760 a small company of Irish, descendants of German Palatines, who had received Methodism, removed to New York, and in 1766, through the influence of Barbara Heck and Philip Embury, resumed the religious services to which they had been accustomed in Ireland. They were assisted by Capt. Webb, an officer in the British army, who had been licensed by Wesley as a local preacher. In 1769 two preachers were sent to America. These found that the country had been greatly awakened by the labors of Whitefield, and they were successful in establishing a church in New York. Whitefield had crossed the ocean 13 times, but in 1770 his work was terminated by his death at Newburyport, Mass. At this time the members in Wesley's societies amounted to 29,179. The period between 1770 and 1780 witnessed no cessation of labor by either branch of Methodism. Although a controversy on the points of difference between Arminianism and Calvinism was carried on with great ability on either side, in which Wesley and Fletcher were opposed by Shirley, Toplady, Rowland Hill, and others, not only were the societies cared for and greatly increased, but also the foundations of those great moral enterprises, the Bible, tract, and missionary societies, were laid, and much attention was given to schemes of public philanthropy. In 1771 Francis Asbury and Richard Wright had been sent to America, where the work had greatly increased, and where the first conference was held in 1773. From 1784 the history of Methodism diverges into two main branches, viz.: Wesleyan Methodism and the Methodist Episcopal church. The first assumed a distinct organic and legal status by the record in the high court of chancery of Mr. Wesley's "Deed of Declaration," and the second became an independent church in America through the ordination by Mr. Wesley and the Rev. James Creighton of Thomas Coke as superintendent and bishop of the Methodist societies in America, and Richard Whatcoat and Thomas Vasey as presbyters. Till his death in 1791, Wesley continued to preside at the annual conferences and to plan and direct the work. Methodism had already been introduced into England, Scotland, Ireland, Wales, the British islands, France, the United States, Nova Scotia, Newfoundland, and the West Indies. In 1791 it numbered 250,540 travelling preachers, and 134,500 members. — Confession. Methodism strove at first only to restore a purified and intensified spiritual life. The careful discussion by Wesley and his fellow laborers, in the conferences and through published works, of the religious needs of the people and of the obstacles to the progress of the work of evangelization, was the occasion of the development of the Wesleyan theology. Methodism has no such elaborate and authoritative symbol as the Tridentine decrees, or the Heidelberg, the Augsburg, the Westminster, and other confessions. The substance of its doctrines is to be found in the writings of John Wesley, John Fletcher, Richard Watson, and others, and in the generally uniform teachings of the Methodist pulpit. The articles which Wesley prepared for the Methodist church in America were taken substantially from the thirty-nine articles of the church of England. Agreeing with the so-called orthodox churches in most cardinal doctrines of the Bible, the material principle of Methodism, like that of all other independent systems of theology, is to be found in its conception of the mutual relation of God and man with regard to the work of salvation through Christ. Methodism holds that the salvation or non-salvation of each human being depends solely on his own free action in respect to the enlightening, renewing, and sanctifying workings of the Holy Spirit. If, in respect to these workings, he holds himself receptively, he will be saved both here and hereafter; but if he closes his heart against these influences of the Spirit, he will continue in death both here and in eternity. With this fundamental view, all the other doctrinal peculiarities of Methodism, such as its dogma of freedom, its emphasis of the work of the Holy Spirit, its views of assurance, Christian perfection, &c., are intimately and harmoniously connected. In accord with this general principle, Methodism is Arminian in distinction from Calvinistic. Teaching the total depravity of the race through the fall of the first pair, and man's consequent absolute inability to recover a state of holiness and obedience, except as aided by divine grace, Methodism teaches that this grace of God in Christ is universal. First, as to the divine purpose: God wills the salvation of all, and Christ died for all. Secondly, as to the work of God for us, or the objective operation of grace: for as by the first Adam
“judgment came upon all men unto condemnation,” so by the second Adam “the free gift came upon all unto justification of life.” Thirdly, as to the work done in us, the subjective operation of grace: it enlighteneth every man, and convinceth every man, thus putting all men under probation; for “the grace of God which bringeth salvation to all men hath appeared.” Methodism teaches that none of Adam’s descendants are held guilty of Adam’s sin until they reject the grace of Christ; i.e., through the atoning work of Christ all men stand in a gracious relation to God, instead of a natural relation, and are subjects of the influence of the Holy Spirit; and they continue in this gracious relation until excluded by virtue of voluntary transgression. With this view harmonizes its teaching relative to infant baptism and salvation, and the responsibility of man for his own salvation or damnation. Methodism holds to two sacraments, baptism and the Lord’s supper. As eligible to the former, it recognizes infant children and believing children and adults; to the latter, professing Christians and penitent seekers of salvation. It prescribes no exclusive mode of baptism, and dictates no exclusive posture in receiving the Lord’s supper. Yet its most usual mode of baptism is by sprinkling, and that of receiving the bread and wine is in the kneeling posture. It emphasizes the doctrine of assurance, i.e., that the Holy Spirit bears witness of pardon and acceptance to the justified sinner; but this is only taught as a privilege of believers, and is not made the test of Christian character. It also makes prominent the doctrine of Christian perfection, or perfect love, declaring the object of its organization to be to spread Scriptural holiness over the land. In accordance with this view, its preachers, previous to being received into its conferences, declare that they are going on unto perfection and expect to be made perfect by the Lord’s grace in the polity. For the polity, like the Methodist confession, is to be understood only by regarding Methodism as a revival and missionary movement. Wesley thought as little of establishing a separate church polity as of publishing a separate theology. The rapidly increasing work caused him and his coadjutors great anxiety. It was their wish and purpose to leave those who had been converted through their ministrations to the pastoral care of the clergy of the establishment. But the neglect and frequent ridicule of the converts by the clergy caused many to turn back and plunge again into sin. Hence Wesley on his departure from London appointed Mr. Maxfield, a young layman, to meet and encourage the members during his absence. Maxfield, through unusual zeal, was led to take a passage of Scripture to expound. Much good followed this attempt. Wesley, however, hastened to put an end to what he regarded a disorderly procedure; but on listening to the earnest and persuasive preaching of Maxfield, he was convinced that this was God’s providential way of providing for the wants of the growing societies. About the same time John Nelson, a mason of Bristol, began to explain to his neighbors the way of salvation which he had found, and to compare and explain the Scriptures. This was the origin of lay preaching, which afterward became so important an element in the economy of Methodism. As the number of lay preachers increased and the number of converts multiplied, Wesley invited several clergymen and these lay assistants, as before mentioned, to meet him in London, “to give him their advice respecting the best method of carrying on the work of God.” This first assembly that took the name of “conference” was held in the Foundery, London, June 25, 1744. That Methodism was yet but a revival within the establishment is seen from the view taken by Wesley and his associates of the relations of the Methodist societies to the church of England. Secession was discouraged, and they distinctly denied that they were dissenters. The hope was still entertained that the regular clergy might be faithful in their care of the people, and administer to them the sacraments. No provision was made for a future assembly, but conferences were held annually thereafter, and the record of their proceedings was published under the title, “Minutes of the several Conversations held by the Rev. Mr. Wesley and others.” Previous to the conference of 1744 the greater portion of England had been divided into “circuits,” and provision had been made to supply these with preachers for such time as the need of the work seemed to indicate. Here are thus found the elements of the circuit and itinerant systems, which have been so generally maintained. During the life of Wesley the conferences were occupied in consultation respecting the best methods of conducting the evangelical work for the ensuing year, in the discussion of doctrinal questions, and in advising the lay preachers as to the proper manner of spending their time in study, preaching, and pastoral labors. Till the close of the American revolution there had been no organization of a separate church de jure, although since the conference of 1744 there had been a church de facto, of which John Wesley was the chief head and executive. While in his work as an evangelist he recognized the sole and exclusive authority of the established church wherever the English civil authority was exercised, the discussions of the several conferences, as well as Wesley’s writings and conduct, clearly show that his views of ecclesiastical authority and polity underwent radical changes, and led him, at the recognition of the independence of the American colonies, to provide a separate church organization for the Methodists of America, and at his death to perpetuate his work by constituting the “United Societies” a distinct ecclesiastical body in regular legal form. Methodism holds to
METHODISM

no inspired or divinely imposed church polity. While it believes that certain types of church organization are found in the New Testament, it teaches that no uniformity of church government is obligatory, but that a church is at liberty to adapt its polity and government to its varying exigencies. So with the orders of the clergy. Methodism conceives that three orders early appeared in the church, but denies that these are enjoined in Scripture. Thus in Great Britain it recognizes but one order, while in America it has provided two. Agreeably with its original character as a revival and missionary movement, it feels at liberty to adjust its polity to the demands of its work. Nevertheless its government and usages are essentially similar in all its divisions, as will appear from the separate accounts of them. II. DIVISIONS OF METHODISM. The original body of Methodists in Great Britain are called Wesleyans or Wesleyan Methodists. The principal secessions from this parent body are the Calvinistic Methodists, the Methodist New Connexion, the Primitive Methodists, the United Methodist Free church, the Bible Christians, and the Primitive Methodists of Ireland. There are also several minor divisions.—1. Wesleyans, or Wesleyan Methodists. Although the "United Society," organized in 1739, was the real origin of Methodism, the Wesleyans had no legal status till 1784, and the societies had been under the exclusive control of the Wesleys. They had assembled the conferences, and had directed the religious work. The chapels and preachers' houses had been deeded to trustees for the use of such preachers as John or Charles Wesley should send to them, and, after the death of the Wesleys, of such as the conference should appoint. Near the close of his life, John Wesley drafted the so-called "Deed of Declaration," a plan for the perpetuity of the societies. In this instrument 100 preachers named by Wesley were declared to be the legal conference, and their character and powers were clearly defined. To them was intrusted the duty of filling vacancies as they might occur. By the enrollment of this document in the high court of chancery the conference secured a corporate existence and legal status. The provisions of this deed have remained substantially the same to the present time. These members are technically called "The Legal Hundred." After the death of Wesley the church was greatly agitated by controversies relative to its polity, as well as by the political questions to which the French revolution had given rise. The celebration of the sacraments by its own preachers independently of the establishment, the powers of individual societies, and the relation of laymen to the government of the church, were among the chief subjects in controversy. These were substantially adjusted in 1795 by the adoption of a plan called "Articles of Agreement for General Pacification," although soon after a secession under the leadership of Alex-

under Kilham resulted, and took the name of the Methodist New Connection. After Wesley's death the progress of the Wesleyan Methodists was rapid and substantial. As a revival power it was unceasing in its labors for home evangelization, and as a missionary movement it organized conferences in Ireland, France, Australia, Canada, and the other British provinces of America, and established missions in France, Germany, Italy, Spain, Portugal, continental India, Ceylon, China, western and southern Africa, the West Indies, Australia, and many of the islands of Oceania. It developed a wise and efficient financial system; it has taken active part in the great questions of emancipation and civil liberty; it laid broad the foundations of its educational system, and wonderfully developed its literary and theological character by the works of Thomas Coke, Jabez Bunting, Adam Clarke, Robert Newton, Joseph Benson, Richard Watson, Thomas Jackson, and many others. The doctrines of the Wesleyan Methodists have already been sufficiently indicated. While they have no written confession of faith, they find in the thirty-nine articles of the established church a proximate expression of their doctrinal belief; but the deeds of their churches and the courts of England recognize Wesley's notes on the New Testament and a portion of his sermons as a standard of doctrine. Its polity and government are substantially defined in the "Deed of Declaration." By this instrument the supreme ecclesiastical government is vested exclusively in the hands of the clergy. These meet annually in conference, and continue in session not less than five days and not more than three weeks. The legal conference has power to receive preachers on trial, to receive into full membership on ordination, to pass upon the character of all the preachers, to try charges against any, and to reprimand, suspend, or excommunicate. It is its prerogative to review and revise the proceedings of the subordinate judicatories. These are: first, the district meeting, composed of ministers and laymen residing within a certain district, embracing from 10 to 20 circuits; second, the quarterly meeting, composed of local preachers, stewards, and class leaders, at which meeting, thus composed largely of the lay element of the church, candidates for the ministry are first proposed, and can be rejected without appeal; thirdly, the leaders' meeting, held monthly, and composed of the minister or ministers of a circuit, the leaders of classes, and stewards, the last having in charge chiefly the temporalities of the societies. The members of the various churches are divided into "classes," each numbering from 12 to 20 persons and placed under a "leader," who is to meet the class weekly to inquire after their spiritual condition and give such counsel and exhortation as each may need. The ministry is itinerant, preachers being appointed to a church for a single year, and eligible to con-
time in one circuit not more than three consecutive years. A body composed of one representative from each district meeting constitutes a stationing committee, which prepares a draft of the stations of all the ministers for the ensuing year, and submits this to the conference, where appeals are made and the scheme of appointments perfected in accordance with the demands of the work. Important improvements have been made in this polity from time to time, by which the seemingly oligarchical character of the "Legal Conference" has been modified, and the methods have been made consonant with the voice of the large body of the conference. Yet the essential principles of the original "Deed" are still retained.—In the progress of its history, Wesleyan Methodism has developed various "con- nectorional" enterprises, as its needs have suggested. Among these are the contingent fund, established in 1776, for the support of home missionaries, for deficits of preachers on poor circuits, &c., which is sustained by an annual collection in all the societies, by donations and bequests, and by appropriations from the book room; the children's fund, founded in 1819, for equalization of the support of the children of preachers, according to the numbers and ability of the societies; the general chapel fund, founded in 1818, to relieve embarrassed chapels and stimulate the liberality of the people in repairing and building chapels and preachers' houses, by affording them help according to their own exertions; and the preachers' auxiliary fund, for the relief of superannuated preachers, their widows and orphans. This denomination had early been very zealous in the planting and support of missions both domestic and foreign. These local and unmethodical efforts were succeeded in 1818 by the "General Wesleyan Missionary Society," by which its entire missionary operations were consolidated under a regular board of managers. The amount disbursed in 1873 was about £175,000, and missions in every quarter of the globe. The distribution of books and tracts by the preachers in their circuits was early insisted on by Wesley. In 1782 he and Coke instituted the "Society for the Distribution of Religious Tracts among the Poor." To supply the needs of the people Wesley early had a book store and printing house of his own, which has developed into the Wesleyan book concern, one of the largest publishing houses in England, whose interests are supervised by a book steward and two editors. These have also the general oversight of the official periodicals of the denomination. The originators of Methodism early gave attention to education. In 1739 Whitefield laid the corner stone of a charity school at Kingswood for the neglected miners, which was afterward completed by Wesley. It also became the anxious inquiry at the conferences, Can we have a seminary for laborers? Its school fund was designed for the education of preachers' children at Kingswood, and afterward at Wood House Grove and New Kingswood. In 1887 the Wesleyans formed the "Wesleyan Education Committee," and they have since manifested great interest in educational matters. They have under their control a "Proprietary College" at Sheffield, and a collegiate institution at Taunton, both standing in collegiate relations to London university; a college at Belfast, Ireland; and two theological schools situated respectively at Didsbury and Richmond. They also support an extensive system of day schools, amounting in 1871 to 889 schools and 150,765 scholars, for which teachers are trained at the Wesleyan normal school in Westminster. The statistics for 1873-4 of the British Wesleyan church, including Great Britain, the Irish, French, and Australasian conferences, and the foreign missions, are: members, 607,107; on trial, 32,961; travelling preachers, 1,917; Sunday schools, 7,692; scholars, 261,740.—2. *Calvinistic Methodists.* This branch of the original revival movement arose from a diversity of view between Wesley and Whitefield on doctrinal points, the former advocating the Arminian theology and the latter the Calvinistic. Aided by his patron, the countess of Huntington, Whitefield first erected the celebrated "Tabernacle" near the site of Wesley's "Foundery" in London, and was instrumental in building churches in various parts of the United Kingdom. This branch of Methodism divided into three sects, the "Lady Huntingdon Connection," the "Whitefield Methodists," and the "Welsh Calvinistic Methodists." The first of these branches adhered to the liturgy of the established church, and adopted a settled pastorate. Their numbers are limited, yet they still maintain the Cheshunt college, which was founded by Lady Huntingdon. The Whitefield Methodists have been almost entirely absorbed into the Independent church. The third branch has been successful in labors especially in Wales and among the Welsh in America. It numbers about 60,000 communicants in Wales, and 4,000 in America, the latter divided into four annual conferences.—3. *The Methodist New Connection* originated in 1797. The Wesleyan body had been agitated by various questions of doctrine and polity. Great uneasiness was felt by numbers of preachers and laymen because by the "Deed of Declaration" the supreme government had been vested in the clergy. This dissatisfaction manifested itself in various serious charges made against the ministry by Alexander Kilham, an ordained travelling preacher. These charges were judged by the conference of 1796 to be slanderous, and after trial Kilham was expelled. He drew after him about 5,000 members. The outlines of a constitution were published by a conference convened in 1798, and these laws and rules have been revised from time to time. The conference is composed of equal numbers of clergy and lay members. It has power to make laws and rules every seven years, but
any proposed changes in the general rules must be submitted to the quarterly conferences for examination, and must be approved by two thirds of the ensuing conference. In doctrine and general church usage this body agrees with the parent church. In addition to the home work in England, they support missions in Ireland, Canada, Australia, and China. The "Minutes" for 1874 give: chapels, 677; societies, 827; circuit preachers, 244; local preachers, 1,270; members, 38,563; Sunday schools, 590; officers and teachers, 11,566; scholars, 80,483.—4. The Primitive Methodists originated in 1810, in consequence of a controversy about the propriety of holding camp meetings. These meetings had been introduced into England by Lorenzo Dow, and had proved an efficient means of good to the common people. They were defended and advocated by Hugh Bourne, a zealous layman, but were declared by the Wesleyan conference of 1807, "improper" and "likely to be productive of considerable mischief." On the persistence of Bourne in his labors he was expelled in 1808; and William Clowes, a fellow laborer of Bourne, was expelled two years later. They nevertheless continued their labors with increased zeal and success. In Lancashire and Cheshire a schism in the Wesleyan church led 16 congregations and 28 preachers to be mostly absorbed into the Primitive Methodists. This church is chiefly Wesleyan in theology and discipline. Its annual conference in England is composed of two thirds lay and one third clerical members; in the United States the clerical and lay elements are equal in the annual conference. It has churches in Great Britain, Ireland, Canada, the United States, New Zealand, Australia, Tasmania, and Africa. According to the "Minutes" of 1874, its numbers are as follows: preachers, itinerant and local, 15,904; members, 166,772; Sunday school teachers, officers, and scholars, 656,276; chapels and other preaching places, 5,425.—5. The Bible Christians were organized in 1815 by William O'Bryan, a Wesleyan Methodist local preacher who separated himself from that body on account of irregularities in his methods of work, and visited a destitute district in E. Cornwall and W. Devonshire, where he formed his first class. They have missions in Canada (these became independent in 1854) and Australia. They have a publishing house in England and one in Bowmansville, Canada. In doctrine they are essentially Wesleyan. In all minor courts the laity are in the majority, but every fifth conference must be composed of equal numbers of preachers and laity; to the intervening conferences the laity send one representative from each district. In 1873 this body had 1,991 itinerant and local preachers, 1,072 chapels and other preaching places, 26,427 members, and 58,989 Sunday school teachers and scholars.—6. Other Bodies. The lesser secessions from the Wesleyan church are chiefly the "Band-Room Methodists," who originated in Manchester in 1808; the Primitive Methodists of Ireland, 1816; the Protestant Methodists, 1828; the "Wesleyan Methodist Association," 1833; and the "Reformers," 1849. The last three have recently been merged under the name of the "United Methodist Free Church," which in 1872 numbered 66,907 members. III. METHODISM IN AMERICA.—1. The Methodist Episcopal Church is the original and largest body of Methodists in the United States. Wesley and Whitefield, during their visits to America, had organized no Methodist societies. The nucleus of the first Methodist church in America was composed of immigrants from Ireland who had been members of Mr. Wesley's societies. In 1766 these were formed into a class and instructed by Philip Embury, who had been a class leader and local preacher in Ireland. He was greatly assisted byCapt. Thomas Webb, an officer of the British army stationed in New York, who had been licensed as a local preacher by Wesley in 1765. Webb preached and formed classes during 1768 on Long Island, and in New Jersey, Delaware, and Philadelphia. In the same year the first chapel was dedicated in John street, New York; and in 1770 the first Methodist church in Philadelphia was erected. In 1769 Boardman and Filmore, the first missionaries sent to America by Wesley, arrived in New York and took charge of the work in that vicinity. Nearly contemporaneously with Embury, Robert Strawbridge, a local preacher from Ireland, settled in Maryland and formed a society in Frederick co.; and afterward organized classes in Baltimore and Harford counties. About the same time Robert Williams had immigrated from England, and had formed the first circuit in Virginia and preached in North Carolina. In 1771 Francis Asbury arrived, and the next year he was appointed by Mr. Wesley superintendent of the American societies. He was soon superseded by Thomas Rankin, an experienced and able minister and disciplinarian. The first American conference was held in 1773, and consisted of ten preachers, all of European birth. The societies then aggregated 1,160 members. At the beginning of the revolutionary struggle nearly all the preachers of English descent, except Asbury, sympathized with the cause of the mother country, and returned home. During the war the English church in America was nearly extinguished, and the dependence of the Methodists on the English clergy for the sacraments almost entirely failed them. For this cause a majority of the Methodist preachers determined to provide for their administration independently of the English clergy. This threatened a serious rupture of the peace and harmony of the church. Under these circumstances Wesley in 1780 applied to the bishop of London to ordain at least one presbyter to administer the sacraments among the American Methodists, but was refused. Therefore in 1784 Wesley, assisted by the Rev. Thomas
Creighton and Richard Whatcoat, presbyters, ordained the Rev. Thomas Coke, LL. D., as superintendent of the American Methodist churches, with the instruction that Asbury should be assistant superintendent. On Coke's arrival a general conference of 60 ministers met in Baltimore, Dec. 24, 1784, and approved Wesley's action by unanimously electing Coke and Asbury superintendents. This conference adopted the episcopal form of government, made the episcopal office elective, and held the superintendents amenable to the body of ministers and preachers. The "Sunday Service" and twenty-five "Articles of Religion," were adopted. Thus the church first assumed organic form. From this time the progress of the denomination was rapid and assured. Before the close of the century Methodism had reached the Mississippi valley, had been established in the British Provinces and Canada, had been successfully preached in New England, and had met with great success throughout the middle and southern states. It was the first church to recognize officially the constitution of the United States, and to pledge its loyalty to the government. It had greatly developed its internal polity and divided its territory into annual conferences; had laid the foundations of its benevolent and educational enterprises; had introduced the Sunday school into America; had established a publishing house; had taken advanced ground on temperance; had been active in attempts to ameliorate the condition of the slave population; and had been positive in declaring the general incompatibility of slaveholding with membership in its communion. In 1800 Richard Whatcoat was elected bishop, and in 1808 William McKendree. In 1808 the plan of a delegated general conference was adopted. This body, composed of 90 members, held its first session in 1812. The church, from a single class of five members in 1766, had now increased to 195,567 members and 689, 000. Art. Doc- trines. These are expressed in the twenty-five "Articles of Religion," which, with the exception of the 23d, were prepared by Mr. Wesley from the thirty-nine articles of the church of England. With the addition of the 23d and a few slight changes, they remain as they were adopted by the conference of 1784. Article I. is the enunciation of the usual orthodox view of the nature of God, and the trinity of persons in the undivided Godhead. Art. II. enunciates the orthodox doctrine of the incarnation, natures, suffering, crucifixion, death, burial, and the conciliatory and sacrificial character of Christ's passion. Art. III. recognizes his real resurrection and ascension. Art. IV. asserts the co-equality of the Holy Ghost. Art. V. declares the sole authority of the Holy Scriptures, and defines the canonical Scriptures. Art. VI. defines the relation of the Old and New Testament Scriptures, and affirms the binding power of the moral law. Art. VII. defines original sin, guarding against Pelagi- anism. Art. VIII. describes the condition of man after the fall of Adam, and declares his utter inability "to do good works, pleasant and acceptable to God, without the grace of God by Christ preventing us, that we may have a good will, and working with us when we have that good will." Art. IX. enunciates the Protestant doctrine of justification by faith. Art. X. describes the character of good works. Art. XI. protests against the doctrine of supererogation. Art. XII. treats of sin after justification, declaring that "the grant of repentance is not to be denied to such as fall into sin after justification: after we have received the Holy Ghost, we may depart from grace given, and fall into sin, and, by the grace of God, rise again and amend our lives." Art. XIII. defines the visible church of Christ. Art. XIV. protests against the Roman Catholic doctrine of purgatory, pardon, worship, and adoration, as well as images of relics and the invocation of saints. Art. XV. declares against the practice of the Roman Catholic church in conducting her services in a language not understood by the people. Art. XVI. defines the nature and number of the sacraments, declaring against their necessarily saving efficacy. Arts. XVII., XVIII., and XIX. define more fully the nature and significance of the sacraments. "The baptism of young children is to be retained in the church." The supper of the Lord is to be administered in both kinds. Transubstantiation and the elevation of the host are condemned as unsupported by Scripture or reason. Art. XX. declares the sufficiency of the one and only offering of Christ for all the sins of the whole world, and condemns the sacrifices of masses as blasphemous and deceitful. Art. XXI. affirms the lawfulness of marriage to Christian ministers. Art. XXII. denies the necessity of uniformity in the rites and ceremonies of the church, art. XXIII. declares that every particular church may ordain, change, or abolish rites or ceremonies, so that all things may be done to edification." Art. XXIV. recognizes that "the president, congress, the general assemblies, the governors, and the councils of state, as the delegates of the people, are the rulers of the United States of America according to the division of power made to them by the constitution of the United States, and by the constitutions of their respective states." Art. XXV. denies a community of goods in the Christian church, but enforces the duty of almsgiving, &c. Art. XXV. defines the nature and asserts the right of a Christian man's oath. These articles purposely avoided the questions of Calvinism and Arminianism, and were intended as a broad platform on which all real Christians might unite.—Polity. The polity of the church is clearly defined in the book of its doctrines and discipline. There are five judicatory bodies, termed respectively the "General Conference," the "Judicial Conference," the "Annual Conference," the "Dis-
METHODISM

strict Conference," and the "Quarterly conference." Prior to 1872 the general conference was composed exclusively of preachers elected by annual conferences, also composed exclusively of preachers, so that the constituent body and the delegated body were both wholly clerical. In 1872 a plan was completed for the introduction of a lay element. The general conference now consists of one minister for every 45 members of each annual conference, chosen by ballot by the ministers themselves, and two laymen, chosen by lay electors from the several quarterly conferences within the territory of the annual conference. It meets quadrennially on the first day of May, and is presided over by the bishops. The ministerial and lay delegates meet as one body, though a separate vote can be had provided one third of the ministers or laymen demand it. In case of a separate vote, a majority of both orders is necessary to pass a measure. It is the sole legislative body of the church, limited by certain "Restrictive Rules," all of which rules are subject to revision except the first, which forbids the conference to revoke, alter, or change the articles of religion, or to establish any new standards or rules of doctrine contrary to the present existing and established standards. It elects bishops, missionary and educational secretaries, book agents, and editors of its periodicals, and is also the court of final appeal. The judicial conference is composed of "triers of appeals," seven of whom are elected by each annual conference. It tries bishops who may be accused, and also appeals of members convicted in an annual conference. To try the latter cases, the triers of three conferences must unite; to try the former, the triers of five conferences are required. Their decision is final, except that law questions may be reviewed by the general conference. The annual conference consists of travelling preachers. A bishop is the presiding officer, or in his absence the conference may appoint its president. Its powers are simply administrative. It holds its members responsible, passing their character under examination each year. Its action is subject to review by the general conference. The district conference is composed of the presiding elder of the district, pastors, local preachers, exhorters, and one steward and Sunday school superintendent from each pastoral charge. It licenses local preachers, and recommends them to the annual conference for admission or for ordination. The local preachers are amenable to this body, which also cares for the general financial, benevolent, and educational interests of the district. The quarterly conference consists of the pastor, local preachers, exhorters, stewards, class leaders, and trustees and Sunday school superintendent (if members of the church) of a single pastoral charge, over which it exercises supervision. The leaders and stewards' meeting, composed of the pastor, class leaders, and stewards, cares for the sick and needy, guards the discipline of the members, and has power to recommend for membership and for license to exhort or preach. In common with the Wesleyans, the M. E. church divides its members into classes under appropriate leaders. This church recognizes two orders in the ministry. Its bishops are not diocesan, but have a joint jurisdiction over the whole church. They are, however, since 1872, required to reside severally within certain districts into which the territory was then divided. They preside over the annual and missionary conferences, arrange the presiding elders' districts, station the preachers annually, and exercise a general superintendence over the spiritual and temporal interests of the church. The ministry is itinerant, the ministers not being allowed to remain in the same pastoral charge more than three consecutive years. Admission to the annual conference is preceded by a probation of two years, and the completion of a prescribed course of study. The local preachers are usually lay preachers who are helpers of the regular pastor. Admission to membership is preceded by a probation of six months, to give the candidate time to acquaint himself with the doctrine and discipline of the church; but members of other churches in regular standing are received without probation. The Methodist Episcopal church has rapidly developed its educational and benevolent institutions. It discussed plans of education as early as 1789, and in 1787 it dedicated its first college. In 1817 it opened its first permanent academy, and in 1820 the general conference recommended that each annual conference establish and maintain a seminary. Its first Biblical school, projected in 1839, established at Concord, N. H., in 1847, was removed to Boston in 1867, and now forms a school of the Boston university. In 1874 it had under its supervision and control 27 universities and colleges, with 5,250 students; 69 seminaries and academies, with about 14,500 students; and 5 theological schools, one in Germany and one in India, with 428 students. The total value of school property is about $8,500,000. Its publishing interests received early attention. Its book concern, begun in 1789 on a borrowed capital of $600, has become the largest publishing house in America. The New York concern in 1873 had a capital of $1,053,448, and the Western Methodist book concern at Cincinnati a capital of $467,419. Besides these there are depositories in nearly every chief city of the United States. It publishes a quarterly review, and 5 monthly and 13 weekly periodicals. The missionary society, organized in 1819, superintends both the domestic and foreign missionary work. In 1873 it appropriated $843,149. Its board of church extension was established in 1864; its receipts in 1873 were $119,396 06. The Sunday school union and tract society manage its immense Sunday school and tract interests. It has also a woman's foreign missionary society, and a board of education. Its statistical returns for
1874 give the following figures: bishops, 13; annual conferences, 80; itinerant ministers, 10,845; local preachers, 12,706; members, 1,345,089; probationists, 218,482; Sunday schools, 18,968; officers and teachers, 203,409; scholars, 1,583,227; value of churches and parsonages, $78,516,693. — 2. Methodist Episcopal Church, South. — Methodism was firmly established in the southern states at an early day. It embraced alike in its membership slaves and slaveholders, and slaveholders were found in its ministry. The subject of slavery occupied the attention of the American Methodists even prior to their organization into a distinct church. The members were at first advised to emancipate their slaves. Their local preachers were warned, and suspension and expulsion threatened in case they failed to manumit their slaves, or bought slaves for the purpose of holding them. On the organization of the church in 1784, provision was made for the spiritual care of the blacks, and slavery was declared to be contrary to the law of God and every principle of the revolution. A method was likewise adopted for the extirpation of what was affirmed to be an "abomination." It was determined that persons who should buy, sell, or give away slaves should be immediately expelled, unless they bought them with the purpose to free them. In 1796 the disciplinary question read: "What regulations shall be made for the extirpation of the crying evil of American slavery?" In the answer recommendation was made to the "yearly conferences, quarterly meetings, and to those who have oversight of districts and circuits, to be exceedingly cautious what persons they admit to official stations in our church; and in the case of future admission to official stations, to require such security of those who hold slaves for their emancipation, immediately or gradually, as the laws of the states respectively and the circumstances of the case will admit." The church was requested to maintain a just peace with deep attention till the ensuing general conference, "in order to take further steps in eradicating this enormous evil from that part of the church of God to which we are united." One of the disciplinary provisions of 1804 was that a travelling preacher, the owner of slaves, should forfeit his ministerial character in case of failure to emancipate them where the laws might permit. The church was advised to forward through appointed channels addresses and petitions to state legislatures to secure the gradual emancipation of the blacks. In 1808 it was declared that no slaveholder should be eligible to the office of elder, where the laws will admit of emancipation. In 1812 each annual conference was authorized to make its own regulations relative to buying and selling slaves. The conference of 1816 substantially reaffirmed the regulation of 1808, but extended the ineligibility to all official members. The disciplinary statements were changed from time to time, ever maintaining a distinct protest against the evil of slavery, but guarding the rights of members and ministers in those states where the laws did not admit of the manumission of slaves. The general conference of 1840 declared that "mere ownership of slave property, in states or territories where the laws do not admit of emancipation and permit the liberated slave to enjoy freedom, constitutes no legal barrier to election or ordination of ministers to the various grades of office known in the ministry of the Methodist Episcopal church." At the general conference of 1844, the appeal of the Rev. Francis A. Harding from the decision of the Baltimore conference, suspending him from the ministry for failure to manumit slaves obtained by marriage, was argued, and the decision confirmed, it being held that the laws of Maryland allowed manumission. The case of James O. Andrew, a bishop of the church, who had come into the possession of slaves subsequently to his election, also came before the conference for examination. A resolution "that it is the sense of the general conference that he desist from the exercise of his office, so long as this impediment (slaveholding) remain," was passed by a vote of 111 to 69. After many attempts at reconciliation, the delegates from 18 annual conferences presented a declaration that this action of the conference "must produce a state of things in the south which renders a continuance of the jurisdiction of the general conference over these conferences inconsistent with the success of the ministry in the slaveholding states." This was referred to a committee of nine, who reported a plan in which provision was made for a separation, in case such a contingency should arise. It provided for the peaceful adjustment of boundary lines, and an equitable division of property. The next day after the adjournment of the conference, the southern delegates published a call for a convention of the slaveholding conferences to meet in Louisville, Ky., May 1, 1845. This convention declared the conferences there represented to be a distinct connection under the name of "The Methodist Episcopal Church, South." It also provided for its first general conference, which met at Petersburg, Va., in May, 1846. By a decision of the supreme court of the United States, the property was divided with the southern church in accordance with the provisions of the plan. This church now consists of 57 annual conferences, composed of travelling ministers and lay delegates, four of the latter from each district. The general conference is composed of an equal number of clerical and lay members. In economy and doctrine it is very similar to the Methodist Episcopal church. It has a publishing house at Nashville, Tenn., and a prosperous missionary society. Previous to the civil war it had 21 colleges for males, and 55 collegiate and academic institutions for females. It published one quarterly, two monthly, and eight weekly periodicals. Its mis-
sionary, publishing, and educational interests were greatly crippled by the war, but are now reviving. Its "Minutes" for 1875-7 give the following figures: 3,184 travelling preachers, 5,344 local preachers, 663,106 members, and 670,192 Sunday school teachers and scholars.—3. African Methodist Episcopal Churches. The refusal to accord equal privileges in church sittings, in the administration of the eucharist, &c., to the colored members of the Methodist church, had caused great uneasiness and dissatisfaction. In 1787 they had discussed their grievances in a convention at Philadelphia. In 1816 a general convention of colored Methodists organized a separate church, "in order to secure their privileges and promote union among themselves." At the first general conference in 1816, Richard Allen, a principal leader in the movement, was elected first bishop. The doctrines and government of this church are in accordance with those of the parent body. It has a large concern in Philadelphia, a weekly periodical, one college, and church property to the value of $4,500,000. There are 10 conferences, 7 bishops, 600 travelling preachers, 1,800 local preachers, and 200,000 members. In 1819 a secession from this church was organized, under the title of the "African Methodist Episcopal Zion Church." They annually elect their superintendent, and in 1873 had 694 preachers and 164,000 members. The "Colored Methodist Episcopal Church in America," organized in 1870 from members of the Methodist Episcopal church, South, and in sympathy with her, has 3 bishops, 1,318 preachers, and 67,888 members.—4. Methodist Protestant Church. This body was organized by former members of the Methodist Episcopal church in 1850, primarily for the alleged reason that its government secured to the itinerant ministers the unlimited exercise of the legislative, executive, and judicial powers of the church, to the exclusion of all other classes of ministers, and of all the people. Members of several general conferences had exhibited marked dissatisfaction with some leading features of the government, and a very respectable minority struggled hard to effect important changes. A periodical, "The Wesleyan Repository," was commenced in 1820, and continued to the general conference of 1824. Numerous petitions were presented to that body, praying for a representation of ministers and laymen in the law-making department. Immediately after the adjournment of that conference a meeting was held in Baltimore, when it was determined to publish a periodical, entitled "The Mutual Rights of the Ministers and Members of the Methodist Episcopal Church," "for the purpose of giving the Methodist community a suitable opportunity to enter upon a calm and dispassionate discussion of the subjects in dispute." This meeting resolved itself into a union society, and recommended that similar societies be organized in all parts of the United States, "in order to ascertain the number of persons in the Methodist Episcopal church friendly to a change in her government." This measure was followed by persecution and expulsion of some of the reformers. In 1826 the Baltimore union society recommended state conventions to be held in the several states to inquire into the propriety of preparing one united petition to the general conference of 1828, praying for representation, and to elect delegates to meet in a general convention for the purpose. Conventions were accordingly held, and delegates elected. In North Carolina several members of the Granville union society were expelled for taking part in this convention. In 1827 11 ministers were suspended, and finally expelled, from the Methodist Episcopal church in Baltimore, and 22 laymen, for being members of the union society. They and their friends immediately organized under Mr. Wesley's general rules, taking the title of the "Associated Methodist Reformers." In November, 1827, the general convention, composed of ministers and lay delegates elected by the state conventions and union societies, assembled in Baltimore. This convention memorialized the general conference of 1828 that the government of the church might be made representative, and more in accordance with the mutual rights of the ministers and people. To this memorial the general conference replied adversely. The reformers then withdrew in considerable numbers, in different parts of the United States, and called another general convention in Baltimore, Nov. 12, 1828. This convention drew up 17 "Articles of Association," to serve as a provisional government for the Associated Methodist churches. A subsequent convention, which was held in Baltimore, November, 1830, adopted a constitution and discipline for the government of the Methodist Protestant church. The Rev. Francis Waters, D. D., of Baltimore, was elected president. This constitution opens with an enumeration of the elementary principles which lie at its foundation. It consists of 17 articles, defining the government and discipline of this body. This church agrees with the parent body in doctrine, but differs in ecclesiastical government. The general conference is composed of equal numbers of clergy and laity, elected by the annual conferences in the ratio of one delegate of each order for every thousand communicants. The office of bishop is not recognized, but the president of general conference is chosen by ballot. The annual conference consists of all the ordained itinerant ministers within a district, and it elects its own president. The composition, duties, and prerogatives of the general, annual, and quarterly conferences are quite similar to those of the like bodies in the parent church. In 1858 most of the annual conferences in the free states became intensely anti-slavery, and demanded of the general conference which met in Lynchburg, Va., in the month of May, such legislation as should exclude slaveholders from
the communion of the church. As the general conference refused to comply, 19 annual conferences sent delegates to a convention which met in Springfield, O., Nov. 10, 1858. This convention suspended all official connection with the other portions of the church so long as they tolerated slaveholding. Subsequently these conferences seceded from the Methodist Protestant church, and with a few from the other non-Episcopal Methodist bodies organized the "Methodist Church." This secession reduced the numerical and financial strength of the original church fully one half, leaving to it only 20 annual conferences. The Methodist Protestant church has about 65,000 members, and about $1,500,000 worth of property. The denomination has a book concern in Baltimore, and publishes three periodicals. Its church organ is "The Methodist Protestant," published in Baltimore. It has likewise under its control four literary institutions. The Methodist church had in 1874 24 conferences, 924 preachers, and about 65,000 members. It has a book concern and publishes a paper at Pittsburgh, Pa., and supports a missionary board, a board for ministerial education, and one college.—5. The Wesleyan Methodist Connection of America was organized by a convention of 151 members, ministerial and lay, convened in Utica, N. Y., May 31, 1843. Prominent among its founders were Orange Scott, president of the convention, first editor and publishing agent of the denomination; Luther Lee, an able controversialist and theologian, author of "Elements of Theology;" Edward Smith, and others of large experience and good ability. In doctrine and religious usages this body is strictly Methodist. Its distinctive features appertain to questions of morality and church polity. Opposition to slavery was a principal cause of its organization. The argument ran thus: Slavery is sin per se; therefore slaveholders should be denied a place in the Christian church. A strong position was also taken against intemperance, forbidding the manufacture, sale, or use of intoxicants as beverages, and even the intentional aiding of others so to do. Fellowship with freemasonry and kindred societies is forbidden, as incompatible with the spirit and precepts of the Christian religion. The polity of this denomination unites the connectional and congregational elements. In interests merely local the churches are independent, but those which are general are placed under the supervision of the conferences, general and yearly. In the former, which meets quadrennially, rests the supreme legislative authority, while the latter are for the most part administrative. These conferences respectively elect their own presidents. Equal representation of the laity with the ministry is secured in all the conferences by specific provision. There is but one order in its ministry, that of elders; it is believed that, in the sense of the Scriptures, bishops are but pastors, and deacons supervised the temporalities of the church. Its itinerancy is voluntary, and the pastorate is purely the subject of agreement between pastor and people. There are 16 yearly conferences, mostly confined to the northern states. The connection owns a publishing house at Syracuse, N. Y., where two papers are issued, the "American Wesleyan," organ of the denomination, and the "Children's Banner." The assets are estimated at $40,000. These interests are supervised by a publishing agent, editors, and a book committee consisting of six ministers and six laymen, all of whom are elected by the general conference. The connection has contributed liberally to the cause of Christian education, and has a well organized missionary society, and a society incorporated for the aid of superannuated ministers and the needy widows and orphans of deceased ministers. It had in 1874 about 250 ministers and 20,000 members.—6. Canadian Methodism. Methodism was introduced into the eastern British provinces by Wesleyan missionaries as early as 1765, and was afterward greatly advanced by American itinerants sent out by Coke. Chief among these was Freeborn Garrettson, who reached Nova Scotia in 1785. Though there were classes prior to this time, William Losee, who entered Canada in 1790, is regarded as the first Methodist itinerant minister in that province. Methodism was greatly promoted by laborers from the United States, William Case, Henry Ryan, Nathan Bangs, and others, who in the face of great opposition established societies in both Lower and Upper Canada. Till the war of 1812 this work had been chiefly directed by the Methodist Episcopal church of the United States. The war interrupted this intercourse, and all the preachers appointed to Canadian stations by the Genesee conference were regarded with suspicion. The rival claims of the American and English Methodists were adjusted in 1820 by giving to the English conference the jurisdiction of Lower Canada and to the Genesee conference that of the Upper province. This adjustment did not prove satisfactory. In 1828 the Canada conference, organized in 1824, became an independent Methodist church, with an episcopal form of government, but in 1833 a union with the British conference was effected. A portion of the church resisted this union, and has continued until under the title of the Methodist Episcopal church of Canada. In government and doctrine it is like the parent body. It has three annual conferences, 228 traveling preachers, 225 local preachers, 21,818 members, 30,000 Sunday school scholars, and church property to the amount of $2,140,776, and has charge of two collegiate institutions.
The union of the larger body of the Canadian Methodists with the British conference was discontinued in 1840, but resumed in 1847. In 1873 the British conference granted the petitions of the Canadian and East British conferences to exist as independent organizations. In June, 1874, the Wesleyan conference of Canada was divided into three annual conferences; but in October a union was formed of this conference, the East British American, and the New Connexion Methodist of Canada, under the title of "The Methodist Church of Canada." This new organization has 956 travelling preachers, 100,178 members, more than 100,000 Sunday school scholars, one university, and four collegiate and academic institutions. Other Methodist bodies are the Evangelical Association, organized in 1800, largely German, which in 1874 had 2 bishops, 15 annual conferences, 1,213 preachers, 1,184 churches, and 90,249 members; the United Brethren in Christ, also mostly German, organized in 1800, which in 1872 had 42 annual conferences, 1,709 preachers, 3,912 organized churches, and 120,445 members; and the Free Methodist church, organized in 1860, which in 1874 had 2 superintendents, 8 annual conferences, 170 preachers, and 8,000 members. IV. LITERATURE. Of the immense literature of Methodism, besides the works and biographies of its founders and early promoters, may be mentioned the following: "Annual Minutes of the Methodist Conference"; "Minutes of the Annual Conferences of the Methodist Episcopal Church" (29 vols. 8vo); "Journals of the General Conference of the Methodist Episcopal Church" (12 vols. 8vo); "History of the Religious Movement called Methodism," by Abel Stevens, D. D. (3 vols. 8vo, New York, 1801); "History of Methodism" by George Smith (5 vols. 8vo, 1802); "History of the Methodist Episcopal Church," by Nathan Bangs, D. D. (4 vols. 12mo); "History of the Methodist Episcopal Church," by Abel Stevens, D. D. (4 vols. 8vo); "History of the Discipline of the Methodist Episcopal Church," by Robert Emory, with additions by the Rev. W. P. Strickland; "History of the Great Seccession," by Charles Elliott, D. D.; "The Oxford Methodists," by the Rev. L. Tyerman (London, 1873); "History of the Organization of the M. E. Church, South," by A. H. Redford, D. D.; "Annals of Southern Methodism," by the Rev. Charles F. Deems; "History of Methodism in Canada," by G. F. Playtor; "History of Canadian Methodism," by the Rev. John Carroll (4 vols. 8vo); "History of the Missions of the Methodist Episcopal Church," by the Rev. W. P. Strickland (Cincinnati, 1850); "Theological Institutes," by the Rev. Richard Watson, D. D., with an analysis by the Rev. John McClintock, D. D.; "Systematische Theologie einheitlich behandelt," by William F. Warren, D. D. (8vo, Bremen, 1865); "Defence of our Laws," by Bishop Emory; and "Church Polity," by Abel Stevens, D. D. For a complete bibliography of Methodism down to 1865, see the above work of Dr. Warren.

METRE, and Metric System. See Weights AND MEASURES.

METRONOME, an instrument for measuring time in music. It is a kind of pendulum whose centre of oscillation is beyond the point of suspension, contrived so that it may be easily carried about and placed conveniently on a table. The first metronomes went without clockwork, consisting simply of a rod with sliding balls at either end, and suspended near the middle on a horizontal rod which served as an axle. (See MECHANICS.) The modern instrument is kept in motion by clockwork, and usually consists of a wooden pyramidal box on the front of which is a graduated scale of figures numbering from above downward. A pendulum, bearing a sliding weight a and a bob b, has its rod graduated with marks corresponding to those on the scale. As the sliding weight is moved up, the centre of oscillation is moved further beyond the point of suspension c, and the vibrations take place more slowly. The scale in the instrument from which the drawing was made has a range from 40 to 208, the numbers corresponding to the number of beats per minute, which is the unit of time. In some instruments a bell has been added, arranged so as to strike at the beginning of each bar. The knob shown at d moves the bell by means of a slide; e is the key for winding. Modern composers are in the habit of marking their compositions with the metronomic signs, and many of the principal works of the older composers have recently been thus marked by the editors. These signs consist of a note together with its numerical or metronomic value. For example, if a movement is marked $\frac{2}{4} = 120$, that implies that when the sliding weight is set at 120 on the scale the pendulum will vibrate once to each quarter note in the bar. Similarly, $\frac{3}{4} = 80$ would signify that when adjusted at 80 the pendulum would vibrate once to each half note. The credit of this invention is usually given to Maelzel, but it more properly belongs to Diederich Winkel of Amsterdam, who made the first instrument about 1815. Maelzel improved upon it somewhat, and appropriated the invention.

METTERNICH. I. Clemens Wenzel Nepomuk Lothar, prince, an Austrian statesman, born in
Coblentz, May 15, 1773, died in Vienna, June 11, 1859. He first appeared in public life as master of ceremonies at the coronation of Leo-

polis II. (1790). Subsequently he studied juris-

prudence for a time in Mentz, made a jour-
nery to England in 1794, became Austrian ambas-

sador at the Hague, and married in 1795 the

granddaughter and heirress of Prince Kaunitz,

whose large domains, added to his own patri-

moniy, made him one of the wealthiest land-

holders of Germany. He attended the con-

cgress of Rastadt in 1797-9, and was ambas-
sador in Dresden in 1801, in Berlin in 1808-4, and in Paris in 1806, where Napoleon received

him with the remark: "You are very young to

represent so powerful a monarchy."

"Your

majesty was not old at Austerlitz," replied

Metternich. In 1807 he concluded at Fon-
tainebleau the convention by which Braunau

was restored to Austria, and the Isonzo river

made the boundary of Italy. In 1809, on the

outbreak of the war between Austria and

France, Metternich joined the emperor Francis

in Hungary, and succeeded Count Stadion as

minister of foreign affairs. In 1810 he con-
ducted the negotiations with Champigny in re-
gard to Napoleon's marriage with Maria Lou-

isa, and subsequently escorted the archduchess

to Paris. Yet he never ceased to watch the am-

bition designs of Napoleon, and kept himself

in constant communication with the English

and Russian governments. Napoleon, in his

interview with him in Dresden, June 27, 1813,
advised Metternich of conspiring against him,

while professing to conclude with him a treaty

of peace. In fact, while Metternich was ma-

king proposals of peace to Napoleon, a for-

mal treaty was concluded at Reichenbach, by

which Austria agreed to declare war against

France in case the conditions which were to

be proposed at Prague should not be accepted.

This treaty was for a long time kept secret.

The formal declaration of war was drawn up

by Metternich's order, Aug. 11, and the quadru-

plicity alliance was concluded by him at

Teplitz, Sept. 9. Metternich's great influence

in this war soon became apparent. The kings

of Bavaria and Wurttemberg were induced to

forsake Napoleon by a secret provision made

through Metternich that they should be pro-

tected against popular disturbances, and should

receive additional possessions. He was re-
warded by the Austrian emperor with the hereditary dignity of a prince of the empire,

conferred on the eve of the battle of Leipzig.

He took a leading part in all subsequent con-

ferences and treaties. When the congress of

Vienna opened, he was unanimously chosen to

precede over its deliberations. He attended the

congress of Aix-la-Chapelle in 1818, was chanc-

eller of state in 1821, attended the con-

gress of Verona in 1822, and until the revo-

lution of 1848 exercised a remarkable ascen-
dancy over the affairs of Austria and Europe,

as the leading champion of conservatism. He

was strenuously opposed to the policy of

France as inaugurated by the revolution of

1830. After the death of Francis (1835) Met-

ternich remained in office as chancellor and

prime minister to his successor Ferdinand, and

in 1840 and 1841, during the complication of the

oriental question, he exerted his influence in

favor of the maintenance of peace abroad. At

home his iron rule prepared the way for the

revolution which terminated his power (March

13, 1848). Barely escaping with his life from

the people, he fled through Holland to Eng-

land, where he remained till November, 1849.

He next removed to Brussels, and in 1851

returned to Vienna. On his way thither he

visited his estate on the Johannisberg, which

had been presented to him by Francis in 1816,

but which during the revolutionary move-

ments in Germany in 1848-9 had been taken

from his control, and while there received a

visit from Frederick William IV, of Prussia.

Without resuming public office, he continued

until his death to exercise great influence in

political affairs. The prince was fond of let-
ters and art; and in one of his letters to Alex-

ander von Humboldt he remarks that his incli-
nation would have led him rather to the sphere

of science than to that of diplomacy. In addi-
tion to his Austrian titles, he was created by

the king of Naples duke of Portella, with a

pension of 60,000 Neapolitan ducats, and was

made a Spanish duke, while honors and pres-

ents were showered upon him by all European

potentates. II. Richard, prince, eldest son of

the preceding by his second wife (the baro-

ness of Leykam and countess Beilstein), born

in Vienna, Jan. 7, 1829. After officiating as

ambassador in Dresden and as attaché to the

ministry of foreign affairs during the war of

1859, he became soon after the peace of Villa-

franca (July 11, 1859) ambassador at Paris, and

held the post till December, 1871. He was

made hereditary councillor of the Austrian em-

pire in 1861, and privy councillor in 1864. He

married in 1856 his niece, the princess Pauline

(born Feb. 26, 1836), a daughter of Count

Maurice Sándor, and the heiress of vast estates.

The princess became an intimate friend of the

empress Eugenie and a brilliant leader of so-

xiety in Paris during the second empire.

METTRAY, an agricultural and penitentiary

 colony of France, in the department of Indre-

et-Loire, 5 m. N. of Tours, on the railway to

Le Mans. It is a celebrated establishment for

the reformation of juvenile offenders, which

is supported mainly by its own labor, and to

some extent by voluntary donations and an-

nual subscriptions. Frédéric Auguste Demetz

(who was born May 12, 1796, and died at Me-

tray, Nov. 8, 1879) was the founder. He

studied law, and for several years was a jurist

of the court of police correctionelle at Paris.

In order to learn the best way to reform juve-

nile criminals, he investigated the agricultural

colonies in Hamburg, Belgium, and Holland

for the reformation of young offenders, and in

1886 made a tour of inspection of the peni-
tentiaries in the United States. On his return to France, M. Demetz, in connection with the viscount Bretonières de Courtelles, established in 1839 the colony of Mettray, the viscount offering a portion of his own estate for the experiment. In July they assembled 23 young men and began training them for teachers for the young offenders who were to be brought there. In January, 1840, they admitted 12 young criminals, and gradually increased the number, till in August, 1872, 792 were under training; and from the foundation to that date 4,387 had been received. The boys are divided into families of 50; the labor is chiefly agricultural, though various trades are carried on; and the establishment is almost wholly self-supplied, though not entirely self-supporting. After the death of Courtelles (1854) the superintendence of the establishment devolved on Demetz. Demetz published *Projet d'établissement d'une maison de refuge pour les prévenus acquittés à leur sortie de prison (Paris, 1836); Lettres sur le système pénitentiaire (1838); Rapport sur les pénitenciers des États-Unis (1839); Résumé sur le système pénitentiaire (1847); Rapport sur les colonies agricoles (1856);* and an interesting series of annual reports to the *société paternelle* on the condition of the colony of Mettray.

**METZ,** a fortified city of the German Reichsland of Alsace-Lorraine, at the confluence of the Seille and Moselle, 80 m. W. N. W. of Strasburg; pop. in 1871, 51,368, which has been much diminished by French emigration since the cession to Germany. The city is surrounded by a regular system of fortifications, and entered by nine gates with drawbridges. The most important works were commenced by Vauban and Belle-Isle and completed by Cormontaigne; and since the German occupation the fortifications have been improved and extended. The esplanade in the centre of the city is a beautiful promenade; the quarter on the right side of the Moselle contains many steep and narrow streets. Among the principal public buildings are the arsenal, the cathedral, the churches of Notre Dame de la Ronde and of the abbey of St. Vincent, both of great antiquity, the military hospital, the hall of justice, and the public library. Besides many Roman Catholic churches and convents, it contains a Calvinist church and several synagogues. It has manufactories of woollen goods, hosiery, plush, embroidery, beer, tiles, and nails. Its manufacture of silk plush for hats is very extensive.—Metz was known to the Romans under the name of Divodorum, changed subsequently to that of Mediomatrici, having been the capital of that tribe of Belgic Gaul; in the 5th century it was called Mettis or Metis. It became celebrated as the capital of Austrasia, which was afterward called the kingdom of Metz, and which in the middle of the 9th century assumed the name of Lorraine. Early in the 10th century Metz fell into the power of Henry the Fowler of Germany, and subsequently became a free imperial city, famous for its commerce, its brilliant society, and its love of letters and art. As the seat of one of the three bishoprics of Lorraine, it witnessed many commotions caused by the rivalries of the citizens and clergy. In 1552 it was occupied by Henry II. of France, besieged several months by Charles V., and successfully defended by the duke of Guise. It was annexed to France by the treaty of Westphalia (1648). At the beginning of the war of 1870 the third corps of the French army was
stationed at Metz under Marshal Bazaine. Napoleon III. arrived there on July 28 and assumed the chief command. After the defeats at Wörth and Forbach, Aug. 6, about half of the French army was concentrated here, and on the 8th Marshal Bazaine assumed command. On the 14th the emperor with the vanguard left Metz and crossed the Moselle, and on the same day the first attempt of Bazaine to prepare for retreat was checked by the battle of Courcelles. The immediately succeeding battles of Mars-la-Tour on the 16th, and Gravelotte, 18th, drove the French within their fortifications, and Metz was now closely besieged by the Germans under Prince Frederick Charles. The subsequent attempts of Bazaine to break out were defeated, the more important sorties being repulsed on Aug. 26, 31, Sept. 1, 22–23, 27, Oct. 2, and 7–8. On Oct. 27 Metz capitulated, Bazaine surrendering his entire force to Prince Frederick Charles. (See BAZAINE.) By the treaty of Frankfort, May 10, 1871, Metz was included in the cession of the Alsace-Lorraine territory to Germany. For the surrender at Metz Marshal Bazaine was tried by court martial at Versailles, the duke d'Aumale presiding. At the conclusion of the trial, Dec. 10, 1873, the judges declared Bazaine guilty of the capitulation of Metz and of the army in the open field without doing all that was prescribed by honor and duty to avoid the surrender. He was unanimously condemned to death, and to degradation from his rank previous to his execution; but all the members of the court signed an appeal for mercy, which the duke d'Aumale in person presented to President MacMahon, who commuted Bazaine's sentence to 20 years' seclusion. He was sent to the island of St. Marguerite, but escaped Aug. 9, 1874.—See Die Operationen der zweiten Armee vom Beginn des Kriegs bis zur Capitulation von Metz, by the baron von der Goltz (Berlin, 1879).

METZU, Gabriel, a Dutch painter, born in Leyden in 1615, died there in 1658, or according to some authorities in 1669. In his youth he settled in Amsterdam, where he rose to eminence as a genre painter, being distinguished for minute imitation of nature. He painted a few portraits, including one of Admiral Van Tromp now in the Louvre. His pictures bring very high prices.

MEUDON, a village of France, in the department of Seine-et-Oise, built upon an eminence on the left bank of the Seine, and on the Paris and Versailles railway, 3 m. S. W. of Paris and 9 m. S. W. of Fort Issy; pop. in 1866, 5,417. During the siege of Paris, Meudon was occupied by the 11th German army corps, which during the night of Jan. 13, 1871, repulsed a vehement sortie of the troops of Paris. The castle of Meudon, during the latter years of the second empire the summer residence of Prince Napoleon, was burned on Jan. 30.

MEULEN, Antoine Frans van der, a French artist, born in Brussels in 1634, died in Paris, 1690. He was in early youth a pupil of Peter Snayers, a painter of battles, and was invited to Paris to paint campaign scenes in the life of Louis XIV. He passed the rest of his life there, and was esteemed as a painter of battles, hunting scenes, and cavalcades.

MEURSIES, or DE MERS, Johannes, the elder, a Dutch scholar, born at Loosduinen, near the Hague, in 1579, died in Sorø, Denmark, Sept. 20, 1639. He was tutor to the sons of Barneveldt, and in 1619 became professor of history at Leyden, and in 1611 of Greek. The states of Holland conferred on him the title of historiographer, but on the execution of Barneveldt he was subjected to persecution, and in 1625 accepted the appointment of professor of history in the university of Sorø. He wrote numerous monographs on Greek and Roman antiquities, and his collected works fill 12 volumes folio (Florence, 1741–1828).—His son Johannes (1618–94) also distinguished himself as an antiquarian scholar.

MEURTHE-ET-MOSELLE, a N. E. department of France, in the old province of Lorraine, bordering on Belgium, Luxemburg, the German Reichsland of Alsace-Lorraine, and the departments of Vosges and Meuse; area, 2,025 sq. m.; pop. in 1872, 865,437. By the treaty of Frankfort, May 10, 1871, Germany took from France almost one half of the department of Meurthe and nearly the whole of Moselle. By a law of the French national assembly, Sept. 11, 1871, the portions of Meurthe and Moselle remaining were united under the provisional name of Meurthe-et-Moselle. The principal river is the Meurthe. The surface is generally uneven, but none of the hills are more than 700 ft. high, and they are covered with forests, fruit trees, and vineyards. The soil is generally fertile, and the department is noted for the variety of its productions. Among the minerals are iron, copper, lead, building stone, and gypsum. There are some manufactures of linen, muslin, canvas, and woolen stuffs. It is divided into the arrondissements of Nancy, Lunéville, Toul, and Briey. Capital, Nancy.

MEUSE (anc. Mosse; Dutch, Maas; Flem. Maase), a river which rises in the department of Haute-Marne in France, and, flowing mainly N. through Vosges, Meuse, and Ardennes, enters Belgium near Charlemont. From Namur it flows N. E. till near its entrance into Holland, when again it bends N., then flows N. W., and finally W. A little below Gorkum it divides into two branches, one of which takes the name of Merwede, and, after again dividing and forming with its arms the island of Ysselmonde, falls into the North sea amid shoals and quicksands; while the other branch, which flows more to the south, and likewise subdivides into two smaller streams, discharges its waters by these channels into different parts of the same sea. The delta of the Meuse is larger than that of any other European river. Its principal tributaries are: in

Oct. 15, 1690. He was in early youth a pupil of Peter Snayers, a painter of battles, and was invited to Paris to paint campaign scenes in the life of Louis XIV. He passed the rest of his life there, and was esteemed as a painter of battles, hunting scenes, and cavalcades.
France, the Mouzon and the Chières; in Belgium, the Lesse, the Sambre, and the Ourthe; in Holland, the Waal, the Leek, and the western Yssel. The chief cities on its banks are Verdun, Sedan, Mézières, and Charlemon, in France; Namur and Liège, in Belgium; Maestricht, Venloo, Dort, and Rotterdam, in Holland. The river is over 550 m. long, and it is navigable to Verdun, 430 m. from the sea. MSUSE, a N. E. department of France, in the old province of Lorraine, bordering on Belgium and the departments of Meurthe-et-Moselle, Vosges, Harte-Marne, Meurte, and Ardenes; area, 2,368 sq. m.; pop. in 1872, 2,642,725. The Faucilles mountains traverse it from S. E. to N. W., and send off numerous ramifications. The chief rivers are the Meuse, Aisne, Aire, and Orne. Cotton and iron are manufactured. It is divided into the arrondissements of Bar-le-Duc, Commercy, Montmédy, and Verdun. Capital, Bar-le-Duc. MEXICO, or Sea New, a name given in Great Britain to some of the smaller gulls, and especially to the common European species (larus canus, Linn.), called also winter mew. MEXICAN PICTURE WRITING. See Hieroglyphics. MEXICO (ESTADOS UNIDOS DE MEXICO; Aztec, Mexitli), a federal republic occupying the S. W. portion of the continent of North America, between lat. 15° and 32° 42' N., and long. 86° 34' and 117° 7' W. It is bounded N. and N. E. by the United States; E. by the gulf of Mexico and the Caribbean sea; S. E. by Balize; S. by Guatemala; and S. and W. by the Pacific. Its maximum length from the Guatemala frontier to the extreme N. W. limit is 1,990 m.; its maximum breadth, about lat. 26° N., is 750 m.; the breadth in lat. 19°, between Vera Cruz on the Atlantic and Manzanillo on the Pacific, is but 540 m., and the minimum distance between the two oceans, 140 m. from N. to S., is on the isthmus of Tehuantepec. The republic is divided into 27 states, one federal district, and one territory, which, with their areas, population, and capitals, according to statistical reports of 1869 and 1873, but chiefly the former, are as follows:

In the tables for 1878, giving a total of 9,400,000, the population of some states was exaggerated. The most densely populated regions are the table lands and the slopes of the Cordilleras. There are in the republic 18 cities or towns whose population exceeds 20,000; in 12 of them it is above 80,000, and in 5 more than 50,000.—In regard to geographical position, Mexico is highly favored. It lies between two great oceans, has a northern frontier of 1,400 and a southern of 344 m., and a seaboard of 6,806 m., 1,677 m. of which are on the gulf of Mexico and the Caribbean sea, and 4,408 m. on the Pacific, including 2,040 m. of shore washed by the gulf of California. The coasts, being deeply indented, especially in the peninsula of Lower California, with numerous bays and guls, and fringed with capes, points, and promontories, are extremely irregular in outline. The principal gulfs are those of Mexico and California, the first of which ranks among the largest in the world. The more noteworthy bays are those of Caborca, San Juan Bautista, La Brúja, and Tegucce, on the coast of Sonora; Campechey and Tehuantepec, washing respectively the N. and S. shores of the isthmus of Tehuantepec; San Luis, Las Animas, Malaga, Santa Marina, Magdalena, San Francisco or San Sebastian, and Molejé, in Lower California; La Asuncion, Espiritu Santo, and Chetumal, in Yucatan. The principal capes are Catoche in Yucatan, Rojo in Vera Cruz, Corrientes in Julisco, and Pulmo, San Lucas, San Lazaro, San Eugenio, and San Quintin, in Lower California. All the coasts washed by the Caribbean sea and the gulf of Mexico are low, flat, and sandy, except near the mouth of the Tabasco river, where the heights of San Gabriel extend N. E. and S. W. for about 30 m.; but the majestic mountains of Vera Cruz, visible many leagues to seaward, form a picturesque background which relieves the monotony of the shore region of that state. On the Pacific side the coasts, though generally low, are here and there roughened by spurs extending from the Cordillera toward the ocean. Off the N. E. coast of Yucatan are some islands; that of Cozumel, called by the primitive inhabitants of the peninsula the island of Swallows, and by the Spanish conqueros Santa Cruz, has an area of about 300 sq. m., abounds in forests of precious timber, and is celebrated as the shrine to which the ancient Mexicans made pilgrimages.
MEXICO

to worship their idols in temples, the ruins of which are still visible. Cárrmen island or Perla del Golfo, in the bay of Campeachy, is 16 m. long and about 2 m. wide, with a seaport of the same name. Other islands in the gulf of Mexico are the islas de los Sacrificios near Vera Cruz, and the islet on which was built the fort or castle of San Juan de Ulúa just opposite Vera Cruz, famous in Mexican history. Guadalupe, Coros, San Benito, Lobos, and Santa Maria islands are situated off the W. shore of Lower California; in the gulf of California are those of Angel de la Guarda (67 m. long), Tiburon, Cárrmen, and Cerralvo; and the islets of Revillagigedo are about 250 m. to seaward. The harbors on the Caribbean sea, where the commerce is quite unimportant, are excellent; while those of the gulf of Mexico (Progreso, Campeachy, Tabasco, Oontzacoalcos, Vera Cruz, and Tuxpan) have only open road-strips, the shore being unapproachable by any kind of craft during the prevalence of northers; and the ports of Tampico, on the Pánuco, and Matamoros, on the Rio Grande, are not always accessible even to vessels of small draught. By far the most commodious harbors in the republic are those on the Pacific and the gulf of California, the principal being Acapulco, Manzanillo, San Blas, Mazatlan, Guaymas, and La Paz.—The face of the country is extremely diversified. The littoral regions are in general low and sandy, especially on the Atlantic side, where they were probably submerged at no remote period as far as the foot of the mountains. In no part of the republic within 30 m. of the sea does the land rise higher than 1,000 ft., except perhaps in Chiapas, where the chain of the Mexican Andes presents a mural barrier facing the ocean, toward which the descent is exceedingly rapid. But the traveller journeying inland from either side, N. of the Tehuanantec isthmus, climbs by a succession of gigantic terraced mounds to a table land with a mean elevation of 8,000 ft., extending far beyond the northern limits of the republic. On the railway from Vera Cruz to the capital, every variety of climate is experienced within the space of a few hours, and the natural productions peculiar to each are successively passed in review, from the sugar cane, indigo plant, and plantain of the tropics, to the pines, firs, and lichens of the north. The Cordillera of the Andes enters the Mexican territory from Guatemala, and to about lat. 17° 30' extends almost midway between the Atlantic and Pacific oceans; from that point it curves nearly due N. to lat. 21° 15', and approaches the E. coast, attaining its maximum elevation somewhat S. of the parallel of Mexico city, between Toluca on one side and Jalapa and Cordova on the other, where several peaks rise to 15,000 and 17,000 ft. above the sea. Still further N. the Sierra Madre runs N. by W. toward Guanajuato, near which city it widens considerably and separates into three distinct branches, the most easterly of which trends in a generally northern direction through Nuevo León to lat. 24° 30', then bends N. W., and, traversing Coahuila, gradually declines in elevation as it approaches the Rio Grande. The central branch, or Cordillera de Anáhuac, the highest of the three, runs N. W. through Zacatecas, Durango, and Chihuahua, taking successively the names of Sierra de Acha, Sierra de los Mimbres, Sierra de la Verud, and Sierra de las Grullas; about lat. 30° it is united by a system of spurs with two lateral chains, that of Texas to the east, and that of Sonora to the west. The western chain, or Cordillera proper, runs nearly parallel to the last through Michoacan, Jalisco, Zacatecas, Sinaloa, and Sonora, and is linked by spurs advancing westward to the maritime Alps of California. That portion of the Mexican Andes richest in silver is comprised between lat. 16° and 29°, while the niluvial uriferous soil continues a few degrees further northward. A striking similarity between the general structure of the Mexican and that of the South American Andes is observable in the barrancas or vast fissures frequently intersecting the Cordilleras. The backs of the mountains form very elevated plateaus or basins, sufficiently uniform in height to be regarded as one continuous table land. The valley of Mexico is an elliptical plain with an area of about 940 sq. m., fringed on the east, south, and west by lofty peaks, some of which are active volcanoes. Indeed, the plain may be regarded as one vast volcanic hearth, roughened at intervals by isolated hills rising abruptly from the surrounding level. The most elevated summits are at the southeast, where Popocatepetl and Iztaccihuatl tower majestically over all the rest. So regular is the great plateau (formed exclusively by the broad, undulating, flattened crest of the Mexican Andes, and not the swelling of a valley between two mountain ridges, such as the alpine valley of Bolivia or that of Thibet), and so gentle are the slopes where depressions occur, that the journey from Mexico to Santa Fé, New Mexico (about 1,200 m.), might be performed in a four-wheeled vehicle. From Mexico S. to Oajaca, in the centre of the plain of that name, with an elevation varying from 3,000 to 6,000 ft., the route is almost as level as from the capital northward. Traces of volcanic fire, so numerous near the W. coast of Guatemala and in San Salvador, disappear in the gneiss-granite mountains of Oajaca; but they again become apparent, perhaps for the last time toward the north, in the central Cordillera de Anáhuac. There a line of summits, comprising the volcanoes of Tuxtla, Orizaba, Popocatepetl, Iztaccihuatl, Toluca, Jorullo, and Colima, extends, between lat. 18° 15' and 19° 30', almost due E. and W. across the republic, and lies nearly perpendicular to the great axis of the chain of Guatemala and Anáhuac. The following are the principal mountain peaks of Mexico, the first ten being volcanoes, with their heights according to the most recent measurements:
Of the volcanoes, Orizaba, Iztaecuiauilli, Popocatepetl, Toluca, Jorullo, and Colima form an E. and W. line nearly across the republic, and will be found described under their own names. The first four rise far above the limit of perpetual snow. San Martin or Tuxita, in the mountains and near the town of the latter name, in the state of Vera Cruz, emits day and night a column of flame visible far to seaward in the gulf. Its last eruption occurred shortly after the conquest.—Mexico is very imperfectly watered, having comparatively few rivers, and but a small number of these, owing to the peculiar topography of the country, are navigable. The largest is the Rio Bravo del Norte or Rio Grande, which forms part of the boundary with the United States, collecting the waters of the Mexican rivers Conchos (itself of considerable magnitude), Salada, and Sabinas, and of several minor streams. The Pénarco, with its numerous tributaries, drains a portion of Guanajuato, Mexico, San Luis Potosí, and Tamaulipas, and empties into the gulf 5 m. below Tampico. It is navigable by small vessels for about 30 m. from its mouth, which is obstructed by a bar with but 9 ft. of water. The Alvarado and Coatzacoalcos descend from the Ozaca mountains, traverse that state and Vera Cruz, and fall into the gulf 50 and 140 m., respectively, S. E. of the city of Vera Cruz. But for the bar at its mouth and numerous shoals, the Coatzacoalcos might be navigated for a considerable distance by large vessels. The Grimalva or Tabasco takes its rise in Guatemala, enters Mexico by the southern frontiers of Chiapas, which state and that of Tabasco it traverses, and empties into the gulf at the N. E. corner of Tabasco by two mouths. This river passes the capitals of the two states just named, between which it flows under a high mountain; it is deep and often rapid, and in the lower half of its course, which lies through a thickly wooded country, is navigable by schooners. The impetuous Usamasa is also rises in Guatemala, flows through Chiapas and Tabasco, and disembogues in the Laguna de Términos in Yucatán, being linked to the Tabasco by a number of canals or transversal canals. The Chimalapa rises in the same watershed as the Coatzacoalcos and holds a hurried course to Tehuantepec bay. The chief river of Oaxaca is the Verde, descending in the same watershed as the two preceding, and falling into the Pacific about lon. 97° 30' W., after a generally S. W. course of 200 m., passing the city of Oaxaca. From the state of Mexico descend two large rivers to the Pacific: the Mesca and Balbas, which rises near Huasteca on the W. slope of the Sierra Madre, and after a winding course S. W., and S. through Mexico, Michoacan, and Guerrero, falls into the sea at the small but commodious port of Zacatula, which name is often given to the lower portion of the river; and the Santiago or Lerma, rising in the lake of the latter name, and flowing N. W. 325 m. into Lake Chapala, from which it issues at the opposite end, to pursue its course 275 m. further to the port of San Blas. Shortly after leaving the lake it forms a magnificent cascade. Principal among the rivers flowing into the gulf of California are the Colorado, the Sonora, the Mar, Yacata and Colorado; the last is navigable by the largest vessels from the frontier to its mouth. Mexico has 50 lakes and lagoons, the most important of which are those of the valley of Mexico, viz.: Tezcuco, with an area of 99 sq. m.; Chalco, 54 sq. m.; Xochimilco and Xaltocan, 27 sq. m. each; Zumpango, 9 sq. m.; and San Cristóbal, 6 sq. m. Some of them overflow during the rainy season, jeopardizing the city of Mexico, which has often narrowly escaped destruction by inundations. Of the very imperfect system of drainage that exists, a portion was established by the ancient Aztecs, who likewise constructed the canal connecting Tezcuco, Xochimilco, and Chalco. The first of these is navigated by flat-bottomed steamers; but it is the exclusive depository of the city sewage, and to the consequent miasmatic exhalations the insalubrity of the capital is mainly due. Another large and important lake is Chapala, in Michoacan and Jalisco, also navigated by steam. Of the remaining 52 lakes none deserve special mention, although some are of considerable extent.—The geology of Mexico has been but imperfectly studied. The mountains in the extreme southwest are mainly composed of porphyry, with some limestone and clay slate, in which last veins of silver, copper, and lead frequently occur. The Ozaca system is chiefly of granite, especially in the loftiest peaks; and granite forms the rocky foundation of the central table land, where however the upper strata exhibit an extensive superstructure of porphyries rich in precious metals, together with basaltic lavas, trachyte, clay slate, amygduiloid, selenite, serpentine, dolorite, and limestone and sand-stone. The Cerro del Mercado in Durango is said to be one vast mass of iron.—The mineral products of Mexico, so far as hitherto known, are richer than those of any other country, not excepting Peru; and it is supposed upon good authority that still richer mines of silver and gold are likely to be discov-
ered. The quantity of silver annually extracted is estimated at 500 tons, and that of gold at a ton and a half. Almost one half of the total yield is derived from the three great mining districts of Guanajuato, Zacatecas, and Catoce. In 1803 the shaft of the Valenciana mine, which yields an average annual profit of $500,000, had reached a depth of 1,670 ft., being the deepest hitherto opened by the hand of man. The value of the precious metals from the Mexican mines, from the conquest down to 1826, was as follows: 1521 to 1808, $2,027,055,000; 1808 to 1810, $181,000,000; 1810 to 1826, $180,000,000; total, $2,368,922,000. The events of the war of independence constrained many mine owners, mostly creoles, to emigrate; and a number of the most productive mines are still in ruins, notwithstanding the efforts made to reclaim them by foreign capitalists. The whole of the gold and silver extracted from the mines of Mexico up to 1826 is estimated at $4,200,000,000. The seven principal mines of San Luis Potosi alone produced in 1808 silver to the value of $2,176,899.26. The state of Sinaloa is said to be literally covered with silver mines, the foreign property in which is distributed as follows: American, $2,000,000; Spanish, $1,450,000; English, $250,000; and German, $50,000. Mexicans work so many mines and on so small a scale, that accurate statistics concerning them cannot be obtained. Scientific explorers, who visited the Sinaloa mines in 1872, reported that those on the Pacific slopes would be the great source of the supply of silver for the next century. In 1870 there were in Ojaca 83 silver and 49 gold mines; in Sonora, 144, chiefly yielding gold, besides 583 in which, although very productive, the works were suspended. The mines during the colonial period were crown property, and those who worked them paid one fifth of the produce to the king. When Mexico became independent they were declared public property, and miners were required to pay into the national treasury only a small percentage of the yield. Even this tax was afterward abolished, and any one can, by right of discovery, denounce or record a mine, and obtain authority to work a certain number of varas free of tribute. A slight tax is however imposed on melting and coinng it, amounting in 1873 to $166,590.14 for the whole republic. Although the ancient Aztecs do not appear to have possessed regularly stamped coin, their commerce was not exclusively confined to exchange of commodities; they had certain signs of the values of different articles, which consequently took the place of money, and of which Clavigero enumerates five kinds. One of these was cacao beans, counted by *ziquihipilla* or lots of 8,000, or by sacks of 2,400 each. For articles of daily necessity the usual money was scraps of cotton cloth called *patoleuachtli*; expensive objects were paid for in grams of gold carried in quills; and for the cheapest arti-

**MEXICO**

Offered by the Mexican government in 1638 by Don Antonio de Mendoza, the first viceroy. The coinage of colonial times was distinguished into four subdivisions: *moneda macuquina*, irregular polygonal coin stamped without a machine, and having a cross, two lions, and two columns on one side, and the name of the reigning Spanish sovereign on the other, extending from 1535 to 1751; *moneda columnaria*, or pillar coin, 1752-71; *moneda de busto*, or bust coin, 1772-1821; and the coinage struck during the war of independence, 1810-31. Since the establishment of independence there have been two distinct categories, the imperial and the republican. The total issue of macuquina coins was $760,765,406; pillar coins, $461,513,225; bust coins, $929,288,27; total coinage of the colonial period, $2,151,581,958, of which $2,121,474,024 was executed at the mint of the capital, and $30,107,934 (all bust coins) at the mints of Chihuahua, Durango, Guadalajara, Guanajuato, Sumbreada, Zacatecas; $2,082,322.23 was silver, $50,716,830 gold, and $542,893 copper. There were in 1873 eleven mints in the republic: Durango, Guadalajara, Ojaca, Culiacan, Hermosillo, and Alamos, under the direction of the central government, and Mexico, Guanajuato, Zacatecas, San Luis Potosi, and Chihuahua, rented by private individuals; and the aggregate coinage at all of them in the year 1872-3 was $20,374,554, of which $19,686,434 was silver. The total coinage in the Mexican mints from their foundation to June 30, 1873, was as follows:

Of the specie coined in 1863-70 ($20,677,021), $18,422,014 was exported, leaving $2,195,007 for the general circulation. Tin is abundant in Michoacan, and still more so in Jalisco; copper is common in both these states and in Guanajuato and Mexico; and lead is frequently found in almost all the silver mines, and especially in those of Ojaca. In this last state occur vitriol and amethysts, agates, turquoise, and carnelians, the most remarkable beds of all of which are in Mount Cocola on the confines of Tlaxcala. The *gallinoz* stone, a black volcanic product, at times shaded with blue, and susceptible of a high polish, is found in many of the states. Marbles everywhere abound, the green and white varieties of Tepalca being very beautiful. Porphyry, jasper, alabaster, rock crystal, talc, various green stones somewhat resembling emeralds, iron and loadstone (the two last particularly in Chihuahua), are met with in many parts of the Sierra Madre. True serpentine is found in Guanajuato, as are also zinc, antimony, and arsenic. Mercury occurs in that state and elsewhere; but this commodity, now so extensively used in the amalgamation process, is mostly imported, and at enhanced
prices. Gypsum and slate are very common; and coal is said to exist at the head waters of the Rio Sabimas. Sulphur abounds in the craters and on the flanks of the volcanoes, as well as in many of the rivers of Jalisco; the coast of Yucatan afford quantities of amber; and salt is so plentiful in Yucatan, Puebla, Jalisco, and Tamaulipas as to be the object of an extensive export trade. Copperas abounds in Mexico; garnets, found in many parts of the republic, are much esteemed; and Lower California is justly celebrated for the large number and superior quality of its pearls. The fisheries of the avicula margarifera or pearl oyster are carried on along the gulf coasts of the Californian peninsula, and have long been highly productive. In 1873 the value of the shells obtained by 636 divers was $112,030, and of the pearls $64,300. Mineral springs are numerous in every part of the table land and on the slopes of the Cordilleras; the most famous are those of El Peñon and Nuestra Señora de Guadalupe, both in the vicinity of the city of Mexico, from the first of which are extracted large quantities of salt; and the thermal springs of Aguas Calientes.—In point of climate, Mexico, in common with all the Andine territories of Spanish America, is divided into three great terraces: the coast regions, or tierras calientes (hot lands); the mountain slopes, or tierras templadas (temperate lands); and the elevated plateaus, or tierras frías (cold lands). The first region comprises all the country lower than 3,000 ft. above the sea; the second extends from 3,000 to the mean elevation of the central table land, 6,000 ft.; and the third embraces all above this last altitude. The climates are distinguished into hot and dry, and hot and moist; temperate and dry, and temperate and moist; and cold and dry, and cold and moist. Properly there are but two seasons in all Mexico: the dry, from October to May; and the rainy, comprising the remaining months. The heaviest rains fall in August and September. The heat is generally excessive on all the coasts, but especially so at Guaymas, Mazatlan, and Acapulco, on the Pacific, and Vera Cruz, Mérida, Sisal, and Progreso, on the gulf. The mean annual temperature at Guaymas is 104° F.; that in all the tierras calientes is from 73° to 85°; in the tierras templadas, from 63° to 72°; and in the so-called cold regions, from 55° to 60° in the dry season, and never rising higher than 80° in the wet. The healthiest localities are those enjoying a dry climate, whether hot, temperate, or cold; and the most unhealthy, those in whose climate humidity prevails. The extreme rarefaction of the atmosphere in the highlands renders acute lung diseases common, and particularly pneumonia; and disorders of the digestive organs are likewise frequent and fatal. Yellow fever and black vomit, the great scourges of the coast regions, usually set in at Vera Cruz about the end of May, and last till November. At Campeachy, Tampico, and Acapulco the season often passes without a single case, intervals of six or even eight years sometimes occurring between the visitations at the last named port. But no such reprieve is ever enjoyed at Vera Cruz, Mérida, or any of the coast towns of Yucatan, at all of which the mortality is generally very great.—The soil of Mexico is for the most part extremely fertile. The comparatively few exceptions are nearly all attributable to insufficient irrigation. Artificial irrigation is secured by means of canals and aqueducts or dams. The value of the landed property of Mexico is set down as follows in an official report for the year 1873: municipal, $147,819,162 20; rural, $174,641,761 31; total, $540,791,469 17. The minister of finance remarks, however, that triple that amount ($1,022,374,299 54) would more nearly approximate the truth. The magnificent arboreal vegetation embraces 114 different species of building timber and cabinet woods, including oaks, pines, firs, cedars, mahogany, rosewood, &c.; 12 species of dye woods; 8 of gun trees; the caucho or India rubber, copal, liquidambar, camphor, turpentine pine, mezquite (yielding a substance similar to gum arabic), dragon tree, and the almácigo or calitiria quadrivalvis, from which sandarach is extracted. Among the oil-bearing trees and plants, of which there are 17 varieties, are the olive, cocoa palm, almond, sesame, flax, the tree yielding the balsam of Peru, &c. The maguey plant furnishes the natives with wholesome beverages, and in some instances also food, while the fibre is an excellent substitute for hemp. The fermented juice, called pulque, is the favorite beverage of the Indians, and is much liked by many of the whites; and a sort of brandy, mezcal, also prepared from it, is highly intoxicating. The value of the trade in pulque for 1862 was reported at $1,487,323; in 1866, at $2,577,826; but both have considerably increased with the facilities for rapid transport afforded by the Mexico and Vera Cruz railway opened in 1878. A special train called the "pulque train" runs every day between the capital and Sultepec. There are 59 classified species of medicinal plants; and many more are mentioned by botanists as still unclassified by science. Jalap is exported to the extent of $50,000 per annum; the United States alone took $10,000 worth in 1873. The annual export of jalap at the beginning of the present century was 170,000,000 lbs. Every variety of edible fruit known in Europe or America is found in Mexico, almost all growing spontaneously; and owing to the peculiar structure of the country, all of them, as well as every kind of European garden vegetable, may be obtained in the markets of the capital throughout the year. Agriculture is assiduously but laboriously carried on by the natives, who persist in using the implements of their ancestors, to the almost absolute exclusion of efficient modern appliances. One of the chief cultivated products is maize,
of which three and even four abundant crops are obtained annually in many districts, and which thrives in all parts of the country. The yield is often 500 fold; and the Indians make it, with beans and chilli, their almost exclusive food. Wheat gives an increase of 60 fold, and rice of about 45. Several varieties of beans are grown; also barley, rye, lentils, potatoes, sweet potatoes, peas, cumin and coriander seeds, &c. Cotton, coffee, cacao, the sugar cane, tobacco, indigo, and cochineal are the staple productions of the hot and temperate regions. The cotton crop of 1873 in Sinaloa comprised 550,000 lbs. at an average price of 20 cents; the cotton district of San Juan Evangelista produced 1,342,104 lbs. in 1872. The coffee of Colima, with an annual yield of about 30,000 lbs., is reported equal in quality to the finest Mocha. That of Vera Cruz (Jalapa and Cordova) is likewise much esteemed; the shipments of it to the United States in 1873 amounted to $299,942. The great cacao center is Chajaca, where its three yearly crops render its culture the most profitable in the state. Sugar is made in large quantities in Vera Cruz and elsewhere. The tobaccos of Tabasco and Vera Cruz are quite equal to the finest of Cuba. The annual value of the food crops of Mexico may be estimated at about $58,000,000, and of all agricultural productions at $110,000,000. The flowers of Mexico are among the richest and most varied in the world; and several of the streets of the capital on Sunday mornings are literally enameled with flowers of brilliant hue and fragrant odor. Grapes flourish in Coahuila, Nuevo Leon, and Aguas Calientes, where, as in Sinaloa, wines, brandy, sugar, and raisins are made from them.—The manufactures of Mexico are comparatively unimportant. Except those of tobacco, cacao, sugar, and indigo, none are exported, and but few can fully meet the home demand. Very good woolen and cotton cloths are woven in Durango, Guanajuato, Jalisco, Nuevo Leon, Mexico, Puebla, and Vera Cruz, and the rebozos (a species of shawl) of silk and linen, and the harness and saddles, are unequalled in any of the other Spanish-American countries. Sugar is manufactured largely and of good quality, the state of Morelos alone frequently furnishing 50,000,000 lbs. yearly. There are paper mills in Guadalajara and elsewhere. Glassware, porcelain, and earthenware of superior quality are made; also hats, chocolate, laces, flowers, liquors, gunpowder, &c.; and there are iron foundries and flour mills in many of the states. The silver and goldsmiths excel in the execution of filigree ornaments; and the Indians of Mexico, Guanajuato, and Guadalajara are skilful in the manufacture of clay and rag figures, almost worthy to rank with works of sculpture. The figures represent muleteers, water carriers, soldiers, and such like, with perfect accuracy of costume, and sometimes portraits from life, or from photographic pictures. Beer and pale ale of excellent quality are made in several breweries in the capital. The dulces or sweetmeats of Guadalajara are much sought after both in and out of the republic.—The fauna includes three species of large felidae, the puma or American lion, jaguar, and ocelot; among the smaller is the wild cat. Wolves are common in the northern states, and also the coyotl or coyote; besides which there are bears, wild boars, and bisons. A species of sloth is found in the southern forests, with five varieties of monkeys. Of the other wild animals the principal are hares, rabbits, squirrels, two or three kinds of deer, beavers, moles, martens, and otters. All the domestic animals introduced by the early Spanish settlers have multiplied prodigiously. The horses, though small, retain the spirit and graceful forms of the Andalusian stock from which they mainly sprang. The rivers and lakes abound in excellent fish; turtles are taken in considerable numbers on the coast, and the carey of Yucatan and Guerrero is the object of a trade valued at $20,000 yearly. The opthalmians are represented by a few bony in the southern forests, and several species of snakes, some extremely venomous, as the rattle and coral snakes. The largest lizard is the iguana, whose flesh is by some of the natives considered excellent food. Noxious insects infest the hot regions in myriads; alacranes or scorpions, in two distinct varieties, are everywhere feared, and it is said that many children are killed every year by their sting; and scolopendras, gigantic spiders, tarantulas, and mosquitoes abound. Bees are numerous, and their wax is an article of export; and the silkworm, though comparatively neglected, is said to yield an annual profit of $40,000. The birds of prey are eagles, hawks, and zopilotes or turkey buzzards, the scavengers of the coast towns, with three or four species of owls. Domestic fowl are extremely abundant. The parrots, humming birds, trogons, &c., vie in richness of plumage with those of Brazil; and the Mexican songsters, the prince of which is the zenozotle or mocking bird, are unequalled by those of any other country.—The population comprises about 6,000,000 Indians of unmixed blood, nearly one half of whom are nomadic savage tribes of the mountainous districts of the north; about 500,000 whites or creoles, chiefly descended from the early Spanish colonists; perhaps 25,000 African or hybrids possessing some negro blood, whether mixed with the European or the Indian element; and mestizos or half-breeds derived from the union of the whites and Indians. Of the Indians there are 35 tribes, speaking as many different tongues and nearly 150 dialects. They are indolent and apathetic, but under prudent direction become good workmen, and often attain to excellence in the mechanic arts; and many of them have been closely connected with the leading political events of the country. The mestizos inherit the vices rather than the virtues of the parent stocks, are
inconstant and turbulent, and, if not the promoters, have been the instruments in many civil wars. The creoles or white Mexicans are in general arrogant, proud, insolent, and reckless, but extremely courteous and hospitable. They are often well informed, but the education of the women rarely extends beyond reading and writing and a knowledge of music. The national costume of the rancho or planter is a close-fitting jacket and slashed trousers adorned with massive gold or silver lace and buttons, and so wide below as to almost cover his immense spurs with rowels two or three inches in diameter. Some of the women still retain the old Castilian black silk dress; but French fashions prevail among the higher classes.—The staple articles of export are silver and gold coin, silver and copper ores, cochineal and indigo and other dye stuffs, with timber, cabinet woods, Sisal hemp, ixtle, &c. The imports are cotton, linen, woollen, and silk fabrics, wrought and unwrought iron, machinery, hardware, provisions, &c. The value of the exports to the United States from Vera Cruz in 1873 was $872,616; to Great Britain from the whole country in 1872, $3,217,020. The whole foreign trade of the republic in 1873 was: exports, $25,500,000; imports, $28,000,000. The annexed table shows the relative proportion of imports from different countries:

Systematic smuggling is so prevalent that the official figures representing the imports of all kinds of goods and the exports for bullion may safely be doubted. The duties collected in the year ending June 30, 1870, amounted to $17,503,945, of which $8,274,572 were received at maritime, and $9,029,373 24 at frontier custom houses. According to the latest official report, published in November, 1873, the shipping movements at all the ports of the republic in 1870 were as follows:

<table>

Of the number of vessels entered, 362 were steamers, and of those cleared, 378. One French and two British lines of steamers ply regularly between St. Nazaire, Southampton, and Liverpool and the gulf ports of Vera Cruz and Tampico, touching at Havana, St. Thomas, Marti- nique, and Santander. The British steamers frequently call at New Orleans. An American line between New York and the principal gulf ports every 20 days, calling at Havana and New Orleans, receives a subsidy of $2,200 per round trip from the Mexican government. Regular communication is kept up between Acapulco and Panama and the intermediate ports of Mexico and Central America, and between Acapulco and San Francisco and the intermediate ports of Manzanillo, Mazatlan, and Cape San Lucas, by two American lines, one of which has a subsidy of $2,500 per round trip, and the other $2,000 monthly, from the Mexican government. In 1872 there were 5,740 arrivals at and 5,095 departures from Mexican ports. The Mexican merchant navy comprises 1,029 craft of all sizes, 357 of which are sea-going or large coasting vessels.—The existing railways of the republic are as follows:

**Mexico to Vera Cruz.** 2834 m.  
Brunel, Apizaco to Puebla. 2514 m.  
Mexico to Tlapozin. 3062 m.  
Vera Cruz (La Zamorana) to Modellin. 11 m.  
Mexico to Guadalape. 47 m.  
*Mexico to Tecopilla and Paso de la * 8 m.  
*Mexico to Atencionplazo. 63 m.  
*Vera Cruz to Puebla via Jalapa. 25 m.  

Total. 3633 m.  

The line from Mexico to Vera Cruz is one of the most wonderful engineering enterprises in the world. It was commenced in 1852, completed in December, 1873, at a cost of $37,000,000, and opened to public traffic through its whole extent on Jan. 17, 1873. About 60 m. of the line extend over the mountain region between the coast and the great Mexican plateau, the elevation of which on the eastern border is nearly 8,000 ft. above the sea. This portion of the road, with an average grade of 2.51 in 100, or 1994 ft. to the mile, carried along the flanks of lofty mountains, through long tunnels, and over bridges spanning deep ravines, affords an opportunity of surveying the grandest and most picturesque scenery on the North American continent. The traffic amounts to about 240,000 passengers and 184,000 tons of freight per annum; the receipts are about $2,500,000, and the running expenses average 60 per cent. of the receipts. The line between Mexico and Atencionplazo is to be extended to Cuautitlan and Toloman. There is a line of horse cars from Matamoros to Paso de Santa Cruz. Several other projects are projected, the most important of which is one from Mexico N. to El Paso, to communicate with the United States railway system. There are 24 regular lines of diligences established between the principal towns of the republic.
MEXICO

The lack of good roads, in a country whose topographical structure deprives it of navigable rivers, greatly retards its material development and prosperity. Large sums were appropriated in 1873 for new highways and for repairs on such as already exist. A network of telegraph wires, 4,345 m. in length in 1874, embraced all the states but Chihuahua, Sonora, and Chiapas, and 655 m. more were in process of construction. The central government owns 1,575 m. of the lines, and state governments 605 m. There are lotteries under the direction of the government, and paying 10 per cent. of the proceeds into the national treasury. Mexico has a federal government, based upon the constitution of 1857, and strongly resembling that of the United States. The executive power is vested in a president elected by universal suffrage for four years, having a salary of $30,000, and aided in the administration by a council or cabinet consisting of the ministers of the interior (gobierno), foreign affairs, justice, public worship and public instruction, public works (fomento), finance, and war. These ministers are appointed by the president. The chief justice of the supreme court unites with his judicial functions those of vice president of the republic. The legislative power resides in a congress, consisting of a lower house, the members of which are elected by universal suffrage for two years, each state being represented in the proportion of one member for every 80,000 inhabitants; and a senate with two members for each state, elected by a plurality of votes in the congress of their respective states, and who must have completed 30 years of age. The congress is by law required to sit from Jan. 1 to April 15 in each year; and a consejo de gobierno or government council holds sessions during the recess of congress. The predominant religion is the Roman Catholic; but all other sects are tolerated, by virtue of a law promulgated in 1873. The ecclesiastical hierarchy consists of three archbishops, of Mexico, Guadalajara, and Michoacan; and ten bishops, of Puebla, Nuevo Leon, Oajaca, Durango, Yucatan, Chiapas, Lower California, Sonora, San Luis Potosi, and Vera Cruz. The revenue is mainly derived from customs, as will be seen by the following table for the years 1871-'2 and 1872-'3:

There is no official report of the national debt. The loans contracted by the imperial government are in their entirety repudiated by the present government. The army comprises 22,387 men, viz.: 15,407 foot, 5,140 horse, 1,463 artillery, and 377 coast guards and invalids. The estimated total expenditure for the army department in 1872-'3 was $10,252,522 92, which would include an extraordinary appropriation of $2,628,939 50.—Public instruction is in a comparatively prosperous condition; the number of schools is steadily increasing, through the liberal appropriations of the central and the various state governments for the development of the system, and the cooperation of private individuals. The following institutes in the city of Mexico are supported by the central government: an advanced school for girls, preparatory school, and schools of law, medicine, agriculture, engineering, fine arts, commerce, and arts and trades; besides which there were in 1873 in the whole federal district 388 schools of all grades, 108 being for females, and the total attendance being 22,407, of whom 8,773 are females. Among these schools were 12 under the jurisdiction of the Lancasterian company, 6 under that of the benevolent society, the schools of the founding hospital and other charitable institutions, private schools to the number of 100, and three for adults, with 248 pupils, 148 of whom were females. In the other states there were 2,592 public schools, of which 3,498 were male primary and 29 male grammar schools; the total attendance at all of them was 165,864, of whom 19,594 were females. The number of public schools for adults was 23, with 935 male and 76 female pupils; and that of the literary institutes 15, with 2,493 students. —The history of Mexico may properly be distinguished into ancient and modern; and the latter is subdivided into two periods, the colonial and that of independence. Notwithstanding the numerous theories advanced concerning the primitive inhabitants of the country, all is still wrapped in profound obscurity. Tradition and the existing remnants of ancient structures point to a more remote and perhaps
a higher civilization than that which filled the early Spanish conquerors with admiration; but neither can assist in determining the name of the origin of the first immigrants. Historic ground in Mexico is not reached until the end of the 6th century; all beyond belongs to the domain of mythology. The Toltecs came to the valley of Mexico, and there built their capital, Tollan (Tula), toward the beginning of the 7th century. According to one theory, they came from Guatemala; another theory represents them as crossing from Asia to America, by a chain of islands which in remote ages stretched at the north from the shores of the eastern to those of the western continent. They are described as an agricultural people, clothed in long tunics, sandals, and straw hats; not very warlike, but humane and civilized, and proficient in the highest mechanical arts; erecting cyclopean edifices; having a worship not sanguinary; and inventing the system of astronomy afterward adopted by the Tezcucaus and Mexicans. The first Toltec dynasty is said to have been founded early in the 8th century by Lozotzin. After a lapse of about 500 years, the kingdom of Tollan, reduced by civil strife, pestilence, and famine, was divided, and many of the surviving inhabitants migrated southward. The Toltecs were the first tribe to leave a written account of their nationality and policy; they are regarded in Mexican history as the primitive nation of the country, and their epoch is taken as the starting point of a fixed chronology for the native annals. With the downfall of their monarchy terminated the civilization of the north. Not long afterward the Chichimecs, described as a fierce northern tribe, living by the chase, dwelling in caverns or straw huts, monogamous, and worshipping the sun as their father and the earth as their mother, came to the Toltec country, which they did not conquer, as they met with no resistance, but merely occupied peacefully, settling in the same towns with the Toltecs who remained from the general emigration. The descendants of these Toltecs became once more numerous and prosperous, and, taking the name of Colhuus or Cuilnas, founded Colhuacan on the margin of the lake. Between the arrival of the Chichimecs and the end of the 12th century, tradition mentions the influx of a multitude of other northern tribes, chief among whom were the Tepanees, who, with Atzcapozalco as their capital, established an independent state, and became gradually so powerful that in later times two of their kings usurped the throne of Tezcuco. Another of these tribes were the Techichimecs, the founders of the Tlaxalan republic; and all of them spoke the Nahua or Nahuatl tongue. After these came the Acoulhuin, likewise of Nahua origin, and consequently kindred to the Toltecs, and especially distinguished among all the immigrants by the Chichimeces as being the most refined. From them the latter readily learned agriculture, the mechanic arts, and town life; and the two races became so completely intermingled as at last to be confounded in one great nation in the kingdom of Tezcuco or Acoulhuacan, a name indicating that not only the customs and culture of the Acoulhuin prevailed, but also their language, which was incomparably more perfect than the Chichimecan. The most important of all the tribes, the Mexicans or Aztecs, although the last to choose a permanent resting place, had been as long in the valley as any of the sister nations. They proceeded from Aztlan, an unknown region of the north, and reached Anahuac about 1193, having made three stations, at which the ruins of casa grandens are still to be seen. (See CASAS GRANDES.) Their first halting place was on the shores of the lake of Teguyo or Teguayo, probably identical with the lake of Timpanogos, or Great Salt lake, in Utah; the second was on the river Gila, and the third not far from the Presidio de los Llanos. After reaching the plain of the lakes, the Mexicans led a nomadic existence for 180 years. After a series of unsuccessful encounters, in which their numbers were greatly diminished, they laid on the islands of the lake the foundations of their city of Tenochtitlan in 1325. Reduced to extreme poverty, and hated by surrounding nations, they resolutely strove against ill fortune until they became numerous and powerful enough to take the offensive. They then spread desolation and slavery through many of the tribes who in former days had shown them little mercy. Their capital was extended, and beautified to an extraordinary degree; they soon became the equals of the Tezcucaus in the cultivation of the arts and sciences; their institutions, customs, theology, and even their language, were propagated wherever their power reached. They occupied the territories beyond which was occupied by Aztec garrisons. The Tezcucaus were perhaps more advanced in knowledge and refinement than the Mexicans; but the latter were certainly far more powerful, and they gave their name to the whole country and to the civilization of their day. The boundaries of the Aztec realm have never been precisely defined; but they extended northward to the country of the Huastecas, whom the Mexicans never subdued; to the northwest the empire did not reach beyond the province of Tula, the vast tract of land beyond which was occupied by the Otomies and some Chichimec tribes; to the west it terminated at the frontier of Michoacan; and on the southwest it was in general only limited by the Pacific; and the greatest length on that coast was from Xoconocho (Soconusco) to Colima. On the Atlantic side the Mexicans possessed all that lay W. of the Coatzacoalcos. The Acoulhuin dominions did not form one eighth of the Aztec kingdom. It should be observed that Ahuizotl, whose reign immediately preceded the Spanish conquest, unfurled his arms successfully into Guatemala, subduing that country and a portion of Nicaragua. The
Tepanecs in 1419 seized the Acolhuacan capital, assassinated the king, and placed their own prince Tegozomoc upon the throne, which was transmitted to his son Moxtia. But Nezahualcoyotl, the rightful heir, succeeded with the aid of the Mexicans not only in driving out the Tepanecs, but in conquering their country, which they gave to their allies the Mexicans. A league of mutual support and defence was then entered into by the princes of Mexico, Tezcoco, and Tlacopan, the conquered countries to be divided between the confederates, and the largest share to be awarded to Mexico. During a century of constant warfare this pact was adhered to with the strictest fidelity. The Mexican monarch had the preponderance in matters of war; the authority of the three was equal in all other concerns; and no one ever meddled with the government of the others. Toward the middle of the 15th century, when the Acolhuacan power began to decline, the Mexican king plundered a portion of his neighbor's territory, and arrogated to himself the title of emperor, though the Tezcuican sovereigns continued to reign until the time of the conquest. These last had the prerogative of crowning those of Mexico.—For the first 27 years after the foundation of Tenochtitlan, the government was in the hands of a body of 20 nobles; but in 1352 it was transformed into an elective monarchy, Acamapichtli or Acamapichtlle being the first king. In the beginning the power of the sovereigns was limited, and their prerogatives were very moderate; but with territorial extension and increased wealth came the introduction of court pomp and pageantry, and such despotism as characterized the reign of Montezuma I. After the election of a king, four princes or lords were chosen from among his nearest of kin, whose voice was indispensable in all state affairs; they acted as senators, were presidents of the royal council, and one of their number was in due time elected successor to the crown, with sole reference to fitness for the office. In later times it was customary to appoint the four candidates to the government of minor states; the one elected must have been general in the army, and not under 30 years of age. When the successor was under age, the government during his minority was committed to the senior of the royal family most fitted for the charge, whose election was confirmed by the kings of Tezcuco and Tlacopan. Three councils or cabinets assisted the king in the administration: one for the revenue, another for war, and a third for the government of the provinces. The councillors or ministers, though necessarily of the nobility, owed their eligibility to long military service and a profound knowledge of state matters. The nobles and priests were the main supporters of the national interests; but the influence of the latter in public affairs was more limited than in some of the earlier monarchies. They had no seat in the privy council, and their functions were chiefly restricted to superstitious exercises and foretelling the issue of campaigns. But they were intrusted with the education of children, were consulted on all grave family concerns, and their social influence was almost unbounded. Profound respect for the main principles of morality was evinced by the ancient Mexicans, with whom the security rather of a person than of property was largely provided for. In the uninhabited districts of the kingdom, public inns were placed at intervals for the gratuitous accommodation of wayfarers, and boats or bridges for their convenience in crossing rivers; and when the roads were damaged by floods, they were repaired at the public expense. A complete system of supreme and subordinate tribunals existed in all the towns, and a still more perfect judicial organization in the neighboring kingdom of Acolhuacan, where a council of all the judges throughout the realm was held once in 80 days at the capital, the monarch in person presiding, for the adjudication of causes left undetermined by the lower courts. The Aztecs were as remarkable for the moderation of their civil as for the severity of their penal code; but their laws seem to have been administered less impartially than in Tezcoco, and to have been somewhat flexible for the nobles and priests. Creditors could imprison their debtors, and had a claim upon their inheritance, but could not enslave the widows or orphans; and slaves about to be sold might free themselves by taking refuge in the royal palace. Adultery was punished with death, however noble the offender might be. For treason or any crime against the person of the monarch, embezzlement of the taxes, &c., the offender was put to death with all his kindred to the fourth degree. Murder, even of a slave, was always a capital crime. Drunkenness in youth was a capital offence; in persons of mature years, though not capital, it was punished with severity; but men of 70 years, and all persons on festive occasions, were permitted the use of wine. He who lied to the prejudice of another had a portion of his lips cut off, and sometimes his ears. Finally, he who robbed in the market, altered the lawful measures, or removed the legal boundaries in the fields, was immediately put to death; and conspirators against the prince, and those who committed adultery with the prince's wife, were torn to pieces limb by limb. The murder of a merchant or an ambassador, or any injury or insult to the latter, was considered a sufficient cause of war. During a series of very cruel wars, all prisoners were devoured or enslaved. At one time the laws were so few that the people knew them all by heart. They were represented by paintings; and the judges were attended by clever clerks, or painters, who by means of figures described the suits and the parties concerned therein. The Mexicans had two sorts of prisoners, one for debtors and persons not guilty of capital crimes, the other a species of cage in
which were confined condemned criminals and prisoners taken in war, both of whom were closely guarded, those doomed to capital punish- 
ishment being sparingly fed, and the others 
abundantly nourished that they might be in 
good flesh when led to sacrifice. For the same 
reason the Mexicans in battle preferred to cap-
ture their enemies alive. Polygamy was per-
mitted, but seldom practised save by the princes 
and nobles. Marriage generally required the 
consent of the parents of both parties; and 
there was a special court for divorces, in which 
a wife might sue. Filial affection was a char-
acteristic virtue of the Aztecs. Except in the 
royal family, sons succeeded to all the rights of 
their fathers; if these died without male 
issue, their rights reverted to their brothers, 
and in the absence of the latter to their neph-
ews. Daughters could not inherit. The gov-
ernment revenues were derived from crown 
lands set apart in the various provinces, from 
a tax on the agricultural products, and chiefly 
from a tribute consisting of provisions and 
manufactured articles; besides which a con-
tribution was received from the merchants and 
craftsmen every 20 or 80 days. The profes-
sion of arms was one of the most esteemed, 
and those who died in defence of their country 
were regarded as the happiest. There were 
four distinct grades of generals, and next be-
low them were captains. The main bodies 
or regiments consisted of 8,000 men, and seem 
to have been divided into battalions of 400 men 
each, and these into squads of 20. They marched 
in admirable order; the priests were always in 
front; and the signal for combat was given by 
kindling a fire and sounding a trumpet. Their 
tactics were unfavorable to hostilities by night; 
but "force and stratagem, courage and deceit," 
says Prescott, "were equally admissible in war." 
The Aztecs were most sincere in the practice of their religious rites. They believed 
in a supreme creator, invisible yet omnipres-
tent, but requiring numerous assistants to per-
form his will, each of whom presided over 
some special natural phenomenon or phase of 
human existence. They had 13 principal and 
several hundred inferior deities. The dread 
Huiztliopochtli, the war god of the Aztecs, 
was the patron deity of the race, and myriads 
of human victims were sacrificed to him yearly 
in countless pyramid temples throughout the 
realm. Quetzalcoatl, a more beneficent deity, 
was described by the natives as a tall white 
man, with a large forehead and flowing beard, 
who taught his favored people the art of gov-
ernment and the various arts of peace, espe-
cially those of the husbandman and silver-
smith; forbade bloody sacrifices, and only per-
mitted those of bread, roses, and perfumes; 
and warned against robbery and all violence. 
This "god of the air," as he was named, hav-
ing incurred the displeasure of one of the other 
chief deities, was compelled to leave the coun-
try; but on quitting the shores of the gulf he 
promised to return, and the Mexicans always 
looked forward to that auspicious day. After 
his departure from the capital, he tarried at 
Cholulal, where a magnificent temple was dedi-
cated to him, the ruins of which are among the 
most curious remains of Mexican antiquities. 
All these divinities were represented by images 
of clay, wood, stone, or precious metals and 
gems, but of most fantastic forms, coarse and 
hideous; and of the minor gods of every de-
gree hosts of images were to be found in the 
dwellings of both great and small. The Mexi-
cans, with all the other polished natives of 
Anahuac, regarded the soul both of man and 
brutes as immortal. The number of priests 
corresponded with the multitude of gods and 
temples; ancient historians affirm that 5,000 
were attached to the great temple of the cap-
itl, on the site of which now stands the cathed-
ral. There were several different orders 
among the priests, the chief of all being the 
two high priests, whose dignity was conferred 
by election. The high priests anointed the 
king, and were the oracles consulted by him 
on all important state concerns. The sacer-
dotal hierarchies of the several gods were quite 
separate, and had each a gradation of their 
own. The temples (tocalli) were of two 
kinds: low and circular, or high and pyrami-
dal, on the tops of which the sacrifices took 
place. For a number of centuries, but there were 
upward of 40,000 throughout the empire, and 
other historians estimate their number much 
higher. There were hundreds in each prin-
cipal city, besides the great temple with several 
smaller ones within its precincts; in each out-
lying quarter of the city were other small 
courts with as many as six temples; and there 
were temples on the mountains and at inter-
vals along the highroads. They were solid 
pyramidal masses of earth cased with brick or 
stone, many of them more than 100 ft. square 
and of a still greater height. The ascent was 
by flights of steps on the outside and one the 
broad flat summit were sanctuaries containing 
the images of the deities and altars on which 
fires were continually burning. Human sacri-
fices, which they made on the most trivial 
occasions, formed the chief religious ceremony 
of the Mexicans and the most important duty 
of the priesthood. In later days the repetition 
of these sacrifices became mournfully frequent; 
some Franciscan monks computed that about 
2,500 persons were annually slaughtered on the 
alts of Tenochtitlan and some of the adjacent 
towns; and "days had been observed," writes 
Herrera, "on which above 20,000 had thus 
perished, reckoning all the sacrifices in several 
parts." Within the temples were schools, col-
leges, and apartments for the priests. A few of 
the priestesses took vows of perpetual celibacy. 
Some of the priests were permitted to marry; 
those of whom chastity was required were pun-
ished with death for the slightest deviation from 
it. When a child of two years was dedicated to 
Quetzalcoatl, a priest with a knife made a slight 
cut on its breast, to confirm the dedication.
MEXICO

Piercing the lips and nose for the insertion of various ornaments, and plucking the hairs of the nascent beard, were common practices among the Mexicans. For purposes of record and communication they had a species of picture writing bearing some relation to the Egyptian hieroglyphics. (See HIEROGLYPHICS.) They had five books written in this way: the first treating of the seasons and years; the second of the days and festivals throughout the year; the third of dreams, omens, and other superstitious observances; the fourth of baptism and the names of children (for they celebrated a baptismal ceremony much like the Christian rite, in which the infant’s lips and breasts were sprinkled with water); and the fifth of the ceremonies and prognostications used at marriages. Historical knowledge was preserved by tradition or by picture writings; and there were, besides the multitudes of regular chronicles, certain men who kept important events, genealogies, &c., in their memory, and recited them when called upon. Translations of elaborate prose productions seem to show that eloquence and rhetorical effect were aimed at by Aztec scholars; but no original compositions have been preserved. Songs perpetuating their traditions, recited at the great festivals, formed one of the foremost branches of temple education. Their musical instruments included various kinds of trumpets, whistles of bone and clay, horns of large sea shells, bamboo flutes, many varieties of drums, and a few stringed instruments. Theatrical performances were given on open terraces in the market places, the stage being covered with branches of trees; masks were indispensable; and the performances were inseparably connected with the religion. The plays were partly pantomimic and partly recitative. The art of prestidigitation was highly developed. Farces and masquerades were frequently given at the temples by the merchants, disguised as frogs, beetles, birds, butterflies, &c., the entertainment ending with dancing. The Mexicans had a simple system of arithmetical notation, in which the first 20 numbers were expressed by a corresponding number of dots. The number 20 was expressed by a flag, and larger sums were reckoned by twenties and expressed by repeating the number of flags. The square of 20, 400, was denoted by a plume; and 8,000, the cube of 20, by an armed or sack. The year was divided into 18 months of 20 days each, and both months and days were expressed by peculiar hieroglyphics. Five complementary days were added to make up the 365; and for the fraction over of nearly 6 hours, required to make the full year, they added 13 days at the end of every 52 years or cycle, which they called xiuhmolpilli, the tying up of years. A month was divided into 4 weeks of 5 days each. The epoch from which the Mexicans computed their chronology corresponded with the year 1091 of the Christian era. They had no astronomical instruments except the dial, but their skill in the science of astronomy is shown by their knowledge of the true length of the year, of the cause of eclipses and of the periods of the solstices and equinoxes, and of the transit of the sun across the zenith of Mexico. Most of their astronomical knowledge was derived from the Toltecs. The physicians were skilful; they had knowledge of several thousand plants and of hundreds of species of birds, quadrupeds, fishes, insects, reptiles, and minerals; but they mystified their cures with superstitious ceremonies. The Spanish conquerors attest the dexterity and success of the native surgeons in dressing wounds and in blood-letting. The merchants and military officers had a fair notion of geography; maps and charts of certain regions, of rivers, and of the whole coast, were accurately drawn on parchment or by picture writings, and there were, besides the multitudes of regular chronicles, certain men who kept important events, genealogies, &c., in their memory, and recited them when called upon.
the rapid transmission of news, towers were erected at intervals of six miles along the high roads, where couriers were always in waiting for despatches, which were transferred from hand to hand at each stage. Despatches were thus carried 300 miles in a day. The different trades were commonly grouped into a species of guild. The women shared equally with the men as well in social festivities as in labor. The Mexicans were simple in dress, but given to an inordinate display of ornaments. The people were courteous and polished, and strict observers of the proprieties of life. Cowering was their posture of respect. In their banquets, which were frequent and costly, human flesh was often served as a special delicacy, particularly in feasts connected with their religion. —The first European to visit the shores of Mexico was Francisco Fernandez de Cordova in 1517; but he only discovered the coast of Yucatan. The discovery was continued in the following year by Juan de Grijalva, in command of a squadron sent from Cuba by Velazquez, who sailed round the north coast as far as the mouth of the river Pánuco, and landed on the islet on which now stands the castle of San Juan de Ulua. After his return, his brilliant account of his discovery excited the desire of conquest. On Good Friday, April 22, 1519, Hernan Cortes landed at that part of the coast where Vera Cruz was afterward built, and founded a town, to which he gave the name of Villarica de Vera Cruz. On the very day of his landing occurred the first of a series of battles which only terminated with the taking of the city of Tenochtitlan, Aug. 13, 1521, and the capture of the young and valorous Guatemozin, the last of the Aztec monarchs. (See Cortes, Guatemozin, and Montezuma.) The other smaller states were subdued after a short resistance. A military government was immediately established, Cortes taking the supreme command, but the ayuntamientos had already been formed, the first at Villarica, and these continued independently of the new military power. Many of the laws emanating from the ayuntamientos still exist in full force in the Mexican republic. By a decree of Charles V., Cortes was constituted governor of the new territory, which had been named New Spain, Oct. 15, 1522. The Indians, though converted, were distributed among the conquistadores and other Spanish officials and immigrants, and compelled as slaves to till the ground and labor in the mines. This system of repartimientos or distributions had already been applied and found fatal to the aboriginal inhabitants of the island of Hayti; but the Mexicans, a hardier people, did not so readily succumb. In 1528 was inaugurated the first audiencia, with Nuño de Guzman as president, and four auditors. The arbitrary and oppressive measures of this body caused considerable discontent in the colony; which, coming to the ears of the emperor, led to the suppression of the audiencias, and the establishment of a viceregal government in New Spain. The first viceroy, Don Antonio de Mendoza, ruled the country from 1535 to 1550. During his administration discoveries were actively prosecuted in the north; the first money was coined in Mexico; the printing press, the first in the new world, was introduced; the university of Mexico and several colleges were founded; and numerous important reforms were effected. Of the 64 viceroys who successively governed the country till 1821, but one was of American birth, Don Juan de Acuña, a native of Lima (1722—34); and the most celebrated after Mendoza was Don Juan Vicente Guemes Pacheco, second count of Revillagigedo (1789—94). In his time were accomplished many important improvements: the streets of the principal cities were drained, paved, and lighted, and provided with a tolerably efficient police; persons of known probity were placed in the public offices; and municipal revenues were introduced. —At the beginning of the present century, society in New Spain consisted of four classes, of opposite tendencies and interests: the pure-blooded Indians, the creoles or pure-blooded descendants of the early Spanish settlers, the mestizos or half-breeds, from the union of whites and Indians, and the Spaniards of European birth. The condition of the Indians had but little changed under the viceroys; they were compelled to pay tribute, and were held in a sort of tutelage which only ended in the tomb. The Indian nobles or caciques were exempted from the degrading restrictions which weighed upon the others. As for the creoles, whose numbers were continually increasing, a policy due to ignorance of their real position in the community excluded them from all places of trust in the government, and even from the higher grades in the regular army. Upon such as had amassed great wealth titles of nobility were conferred, while conciliatory steps were taken to divide the smaller fortunes; but the home government considered it imprudent to allow them to take part in the public administration, and placed it exclusively in the hands of the Spaniards. This, with other grievances, caused profound discontent among the creoles, who would probably have resented it by open rebellion, had they not been restrained by the apprehension that the Indians, aided by the mestizos, might avail themselves of that event for the destruction of all the whites. An ineradicable antipathy had already sprung up between the creoles and the Spaniards, whom they distinguished by the sobriquet of gachupines; yet probably no outbreak would have immediately ensued but for the events of 1808 in the Peninsula. The usurpation of Ferdinand’s throne by a Bonaparte was unanimously protested against by both Spaniards and creoles in Mexico; but the public mind was agitated by temperate discussions concerning the provisional government which the state of things made it necessary to organize; and the excitement was
not a little enhanced by the imprisonment of the vicerey, Don José de Iturrigaray, suspected of a design to seize the crown of Mexico (Sept. 16, 1808). After his arrest the prestige of Spanish authority sensibly declined among the Mexicans, who began to long for independence. A conspiracy was formed, and on Sept. 15, 1810, a revolt broke out in the province of Guanajato, headed by a priest, Don Miguel Hidalgo, a man of much talent and considerable influence among the Indians. The insurrection soon assumed formidable proportions, Hidalgo having at one time 100,000 men under arms. He finally suffered several defeats, was betrayed to his enemies (March 21, 1811), and four months later shot in company with his companions in arms Allende, Aldama, and Jiménez. The contest was continued by 27, and instituted a reign of terror, which resulted in a national congress, which met at Chilpancingo in September, 1818, and in November declared Mexico independent. On Oct. 22, 1814, it promulgated at Apatzingan the first Mexican constitution, which is known by the name of that place. After several defeats Morelos was captured, carried to the city of Mexico, and executed as a rebel, Dec. 22, 1815. For several years the contest was a mere partisan warfare on the part of the patriots, of whom the principal chiefs were Victoria, Guerrero, Bravo, Rayon, and Terán. These were gradually driven from the field, and were killed, imprisoned, or obliged to hide in the mountains, so that long before 1820 the authority of Spain appeared to be fully reestablished in Mexico. But in the course of that year the news of the revolution in Spain, and of the proclamation of the constitution which Ferdinand VII. had been compelled to adopt, renewed the agitation among the Mexicans in favor of a liberal government. Don Agustin Iturbide, a native Mexican and a colonel in the Mexican army, who during the recent civil war had distinguished himself on the royalist side, now threw off his allegiance and began the second revolution by proclaiming Mexico independent, Feb. 24, 1821. The revolt of Iturbide was eminently successful. In the course of a few months the whole country recognized his authority, except the capital, and by a treaty signed at Cordova, Aug. 24, 1821, with the viceroy, Don Juan O´Donoju, he obtained possession of Mexico on Sept. 27, and instituted a regency, of which he was the head and O´Donoju one of the members. Eight months later, with the support of the army and the mob of the city of Mexico, Iturbide was proclaimed emperor on the night of May 19, 1822, under the title of Agustin I. His reign was short. On Dec. 2 Santa Anna, seconded by Bravo, Guerrero, and other chiefs, proclaimed the republic at Vera Cruz; and Iturbide abdicated on March 19, 1823, rather than see the country again plunged into civil war. The congress, which had been dissolved by Iturbide, but reconvened by him shortly before his abdication, appointed a new government, called poder ejecutivo (executive power), composed of Generals Bravo, Victoria, Negrete, and Guerrero. Iturbide was condemned to exile, and embarked at Vera Cruz for London in May of the same year, just twelve months after his exaltation to the throne. On Oct. 4, 1824, the congress promulgated a constitution closely resembling that of the United States, and by virtue of which Mexico was formed into a republic with 19 states and 5 territories. Gen. Don Felix Fernando Victoria, better known as Guadalupe Victoria, one of the most intrepid heroes of the war of independence, was the first president, and Gen. Bravo the first vice president. Iturbide, who had the temerity to venture back to Mexico in this year, was arrested and shot at Padilla on July 19. In 1829 the candidates for the presidency were Gen. Guerrero and Gen. Pedraza; on the election of the former the opposite party took up arms, and a bloody contest ensued, which terminated in the downfall of Pedraza's government, and his flight from the country, Jan. 4, 1829. Guerrero assumed the executive functions on April 1. The year 1829 was marked by the recognition of the Mexican republic by the United States, and by an attempt made by Spain to regain possession of her lost colony. In July Brig. Gen. Barradas with 4,000 Spanish troops disembarked at Cabo Rojo near Tampico, but he was compelled to capitulate on Sept. 11, his troops being disarmed and sent to Havana. The vice president, Gen. Anastasio Bustamante, who was commanding a reserve corps at Jalapa for the purpose of repelling the invaders, pronounced against Guerrero, and, having succeeded in deposing him, was himself elected president in his stead, Jan. 11, 1830. Revolutionary disturbances continued till Feb. 14, 1831, when Guerrero, one of the principal leaders, was treacherously delivered up to his enemies and executed. His name is perpetuated in that of one of the present states of the republic. Bustamante was succeeded by Pedraza, who in turn was deposed by Santa Anna, the latter entering upon office on April 1, 1833, little more than three months after the inauguration of Pedraza. Bustamante was compelled to go into exile, and with him several other personages of political notoriety. Congress now passed laws suppressing the convents, and abolishing the compulsory payment of tithes. It also proposed to appropriate the property of the church to the payment of the national debt, but this measure led to insurrections and to further complications, which ended in 1855 in the abrogation of the constitution of 1824 and the conversion of the confederation of states into a consolidated republic, of which Santa Anna was nominally constitutional president, and practically dictator. This revolution was acquiesced in by all parts of the country except Texas, where several thousand American colonists had settled. The refusal of the Texans to submit to the cen-
tional government, which they pronounced a usurpation, induced Santa Anna to march against them in the beginning of 1836 with an army, which was defeated and annihilated at San Jacinto, April 21, the Mexican president himself being taken prisoner. In the previous month a convention of delegates assembled at the town of Washington had declared Texas an independent republic. The captivity of Santa Anna threw Mexico again into confusion. Bustamante, who had returned from exile, became president April 19, 1837; but in the latter part of his term the power was virtually in the hands of Santa Anna, who, after a visit to President Jackson at Washington, had been sent back to Mexico in a United States ship of war in 1837. He held office as revolutionary provisional president from March to July, 1839, when Nicolas Bravo became president for a week. A long period of confusion followed, during which the constitution was suspended, and the government became a dictatorship, at the head of which were alternately Santa Anna, Bravo, and Canalizo (the two last as substitutes during the frequent absences of the first), from Oct. 10, 1841, to June 4, 1844. Constitutional government was resumed in 1844, with Santa Anna as president, under a constitution promulgated June 12, 1843. He was deposed and banished by a revolution, and was succeeded, Sept. 20, 1844, by Canalizo, who was deposed by a revolution in December. His successor, Herrera, was also driven from office by a revolution, Dec. 30, 1845. During his administration war commenced with the United States, in consequence of the annexation of Texas to the American Union. Herrera was succeeded by Gen. Paredes. In May, 1846, Gen. Taylor crossed the Rio Grande, and after a series of engagements in which the American arms were uniformly successful, Santa Anna, who had returned from exile, regained the presidency, and taken personal command of the army, was completely overthrown. By the treaty of Guadalupe Hidalgo, signed in February, 1848, the war was ended, and California and New Mexico were ceded to the United States. Santa Anna again left the country, but after the new administration of Herrera, and that of Arista, he was recalled in 1853, and was for the fifth time elevated to the presidency, though for a short season only; for having attempted to secure the office for life with the right to appoint at his death his own successor, he was deposed in August, 1855, by a revolution under Alvarez, governor of Guerrero, who was at once appointed to take his place. The latter resigned in favor of Comonfort in December of the same year, and a series of revolutions ensued, chiefly instigated by the so-called church party, whom the president made his implacable enemies by a law recommended by him and adopted in June, 1856, for the sale of the church lands and the freedom of religious belief. In March, 1857, a new and very democratic constitution was promulgated by congress, and Comonfort was constrained to accept it; but, owing to strenuous opposition from the church party, it did not come into operation till May. Mean-
time the repudiation of an acknowledged debt to Spain seemed likely to involve the republic in a war with that power; the president sought in vain for aid from the United States, and conspiracies multiplied on every side. Comonfort, although confirmed in the presidency under the new constitution in September, announced in December a change of government and of constitution; and in January, 1858, he was superseded by Zuloaga, who for a while had been his supporter, and was forced to take refuge in the United States. Zuloaga was immediately opposed by Benito Juarez, who, as chief justice of the supreme court, was by the provisions of the constitution the late president's lawful successor. Juarez was defeated; but he went to Vera Cruz, and there established himself as constitutional president on May 4. Zuloaga was constrained to abdicate in favor of Miguel Miramon, his own general-in-chief, Jan. 1, 1859. Miramon, a successful soldier rather than a good statesman, relied solely upon the fortune of arms for the subjection of Vera Cruz. Leaving Zuloaga as provisional president, he set out upon a series of campaigns, which terminated in that of Calpulalpan and the triumphal entry of Juarez into the capital on Jan. 11, 1861. Much of Juarez's success was due to the recognition of him as the head of the government by the United States. While still at Vera Cruz he began the series of reforms which rendered his administration so popular on the one hand, but on the other paved the way for foreign invasion. Among them stand most prominent the making of marriage a civil contract, the abolition of perpetual monastic vows and of ecclesiastical tribunals, the suppression of monasteries, and the appropriation of church property to the service of the state, the total value of which was estimated at rather more than $300,000,000, or nearly one half the value of all the landed property in the country. These measures were soon followed by the complete separation of church and state. But the church party had resolved upon the destruction of Juarez's government, although national liberty should be sacrificed for its accomplishment. A favorable opportunity soon offered. Spain, France, and England urged claims for the repair of injuries and losses alleged to have been sustained by their subjects resident in Mexico; and no satisfaction having been obtained from Juarez, he was informed that a joint expedition from the three powers would be sent to demand it, a measure agreed upon by the convention of London, Oct. 31, 1861. In December Vera Cruz was occupied by Spanish troops from Cuba, commanded by Gen. Prim, and in January, 1862, by French and British forces. But it was soon discovered that the English and Spanish claims could be settled by negotiation;
it was agreed that a portion of the customs receipts should be appropriated to their liquidation; and in May the forces of both these powers were withdrawn from the country. The French army remained in the republic, thereby tacitly avowing their intention to overthrow the existing form of government in Mexico. This determination appears to have been solely prompted by Almonte and other agents of the church party sent to Europe for that purpose, and it was readily concurred in by Napoleon III. The French refused to treat with Juárez, and war was declared on April 16, 1862. Almonte, appointed president by the Vera Cruz authorities, who had revolted againstJuárez (June 3), was deposed and his government dissolved on Oct. 2 by a decree of Gen. Forey, the French commander. Hostilities began with an attack on Puebla by the French, who were then defeated, but who, after a number of subsequent engagements of varying success, occupied Mexico city on June 10, 1863. Juárez and his ministry having removed to San Luis Potosí, a republic was formed on the 24th; on July 8 an assembly of notables was convened, with power to decide upon the form of the future government of Mexico; and on the 10th it resolved, by 250 votes against 20, upon a hereditary monarchical government under a Roman Catholic emperor. The crown was accepted by the archduke Maximilian of Austria, with the title of Maximilian I., emperor of Mexico. He arrived at the capital on June 12, 1864. The republican president, continually pursued by the imperialists, arrived by successive retreats at El Paso in September, 1865, and remained there until the commencement of the following year. On March 25, 1866, the Juárist troops captured Chihuahua, and that victory was followed by a number of others. After repeated remonstrances from the United States government, the French troops, under Bazaine, were withdrawn from Mexico early in 1867, the last detachment embarking at Vera Cruz on March 16. Maximilian, now left to his own resources, deemed it expedient to leave the capital and proceed northward. Toward the end of February he set out at the head of about 5,000 men, and reached Querétaro, which was at once besieged by Gen. Escobedo with an army of 20,000 Juáristas; Mexico, Puebla, and Vera Cruz being simultaneously invested by other divisions of the republican forces. The ill-fated emperor was captured (May 15), tried by court martial, condemned, and shot, together with his two generals, Miramon and Mejía, on June 19. Juárez reentered the capital on July 16, and was reelected president in the following October. During his flight before the imperial forces in the north he had to issue an official order; but he issued a decree prolonging his exercise of the presidential functions until it should become possible to summon the representatives for a new election. The work of reconstruc-

MEXICO

MEXICO, a state of the republic of the same name, bounded N. by Hidalgo, E. by Tlaxcala and Puebla, S. E. by Morelos, S. by Guerrero, and W. by Michoacán; area, 9,608 sq. m.; pop. in 1869, 650,668. Two great mountain chains traverse the state, and, with their branches, divide it into three picturesque and fertile valleys, the principal of which is that of Mexico, and the other two are Tlaxcala and Toluca. The highest summits are those of the south and attempt on the part of Santa Anna to occupy some of the gulf ports and promote a conspiracy against Juárez, who had rejected his offer to assist him in driving out the invaders. He was captured at Sisal on July 12, 1867, tried at the castle of San Juan de Ulúa, and condemned to banishment for eight years. The years 1868 and 1869 were marked by insurrections, pronunciamientos, and revolutions, the most formidable of which was the pronunciamiento of Angel Santa Anna, who was taken, after four months of depredations and bloodshed, and shot, in company with his followers. President Juárez was again elected in 1871, the opposing candidates having been Gen. Porfirio Díaz and Don Sebastian Lerdo de Tejada. Juárez is remarkable as having been the first president of Mexico who held power during his full term of office. He died on July 18, 1872, and was succeeded by Lerdo de Tejada. The republic is at present (1875) in a state of comparative peace; the laws are more faithfully observed, or at least less disregarded; the military seem to be reconciled to the idea of enduring a civilian at the head of the government; public education is in a prosperous condition; internal improvements are in progress; brigandage is gradually disappearing; and mining is likely to be extended before long by the adoption of suitable machinery.—See Solis, Historia de la conquista de México (Madrid, 1864; new ed., Paris, 1888; translated into English, 2 vols., London, 1724); Boletín de la sociedad de geografía de México (1854 et seq.); Fimentel, Cuadro descriptivo y comparativo de las lenguas indígenas de México (2 vols., Mexico, 1862); Orozco y Berra, Geografía de las lenguas de México (Mexico, 1864); Payno, Historia de México (Mexico, 1871); Clavigero, Historia antigua del México (4 vols. 4to., Cesena, 1780–58; translated into English, 2 vols. 4to., London, 1787; Spanish, London, 1824); Humboldt, Essais politiques sur la Nouvelle Espagne (revised ed., 4 vols. 5vo, Paris, 1827); Lord Kingsborough, "Mexican Antiquities" (9 vols. fol., London, 1811–49); Prescott, "History of the Conquest of Mexico" (1843; revised ed., 3 vols., Philadelphia, 1874); Brantz Mayer, "History of the War between Mexico and the United States" (New York, 1848), and "Mexico, Aztec, Spanish, and Republican" (1852); Mansfield, "The Mexican War" (New York, 1848); Kendall, "The War between the United States and Mexico" (New York, 1861); Helps, "The Life of Hernando Cortes, and the Conquest of Mexico" (London, 1871).
southeast, among which are Popocatépetl and Iztaccíhuatl. The chief and only important river is the Lerma, which, rising in the lake of its own name, flows N. W. into Michoacán and falls into Lake Chapala. The most remarkable feature in the hydrography of the state is its lakes: Chalco, Xochimilco, Texcoco, Xaltéven, San Cristóbal, and Zumpango in the valley of Mexico, and Lerma in that of Toluca. The average elevation of the state is 7,500 ft. above the sea. Its climate is equal to the mildest, most equable, and most salubrious of the temperate zone; the mean annual temperature is 65° F., the thermometer never descending below 57°, while the maximum summer heat is 70°. There are really but two seasons, the rainy from June to October, and the dry during the remaining months. The metals found here are gold, silver, lead, iron, and antimony; cinnabar and sulphur abound; some coal occurs; and lithographic stone and marbles of several varieties are plentiful. The soil is remarkably fertile, and the state, one of the most agricultural in the republic, produces maize, wheat, rye, barley, several kinds of beans, the sugar cane, plantain, and especially the maguey. Tropical fruits abound here, and all the fruits and vegetables of the temperate zones. The forest-clothed hills and mountains afford an abundance of timber of several varieties. The chief industries are mining, agriculture, the manufacture of woollens and cottons (the cassimeres and other fabrics of Temoscaltepec and Tenancingo being of superior quality), and glass and earthenware, some of which is not inferior to that imported from Germany. Cattle rearing, once a vast source of wealth, has materially dwindled of late years, the annual value of the stock not exceeding $3,000,000. The commerce is valued at $12,000,000 yearly. This state is traversed by the Mexico and Vera Cruz railway, and those of Tlalpan and Toluca, and by several lines of telegraph. The state is divided into 16 districts, and the capital and chief town is Toluca. In 1874 there were 388 primary public schools, of which 336 were for males, and the total attendance was 22,129, about 3,000 of whom were females. Of the 51 private schools 34 were for males; the aggregate attendance was 2,829, and of these 1,027 were females. The only high school supported by the state government is the Instituto Literario, with 670 students, the annual outlay for which is $36,000.

MEXICO, a city and the capital of the republic and of the federal district (area, 85 sq. m.) of Mexico, situated in the centre of the valley of Mexico, and in the great central table land of the country, at an elevation of 7,469 ft. above the sea, according to Humboldt, or 7,602 ft. by Talcott's measurement; lat. 19° 26' N., lon. 99° 7' W.; pop. according to an official return in 1869, 200,000; according to later authorities, about 250,000. Of the natives, the whites are the least numerous element, the mestizos and pure-blooded Indians forming by far the largest proportion; and there are besides many Germans, French, Italians, Spaniards, and other Europeans, with some Americans. The Germans are either manufacturers or brewers, or are engaged in the higher branches of commerce; the French and Spaniards are mostly retailers, the former dealing in articles of fancy and luxury; the English are for the most part bankers, or, like the Americans, are connected with mechanical and engineering enterprises. The various public vendors, muleteers, water
MEXICO

Carriers, domestics, &c., are commonly Indians or mestizos. Beggars are extremely numerous, and the ragged vagrants are called lepers or lepers. Mexico ranks among the largest cities in the western hemisphere, and, with its steeples, towers, and domes, presents, from whatever direction approached, an aspect of grandeur and magnificence unsurpassed by any in the world. It is divided into 8 cuarteles mayores or large wards and 32 smaller, comprising 245 blocks or squares of houses, 350 streets, and 130 callejones or lanes. The streets are wide and straight, crossing each other at right angles, well paved, lighted with gas, and furnished with spacious sidewalks, a feature rarely met with in Spanish-American towns. The houses, especially in the central and W. portions, are mostly of three stories, strongly built of stone, often painted in brilliant colors, and having a balcony before every window. Mexico is lavishly supplied with public squares, the finest of which is the plaza de Armas, in the middle of the town; the centre is laid out in a garden with flower beds, shady trees, and benches, and a band is in attendance almost every evening. The plaza is 810 ft. long by 600 ft. wide. On the N. side, occupying the site of the ancient Aztec pyramid and teocalli, stands the cathedral, a majestic edifice, though the architecture is an irregular mixture of the Gothic and Italian styles. The front is decorated with carving, and there are two lofty towers ornamented with statues. The interior is rich and gorgeous, and the numerous crucifixes, candlesticks, reliquaries, &c., of gold and silver adorned with jewels, are said to be of immense value. In the vaulted roofing is a much admired painting by Juneiro. The cathedral is 500 ft. long by 420 broad. It was founded in 1553 under the auspices of Charles V. and Pope Clement VII., and completed in 1667. The E. side of the plaza is occupied by the government house, containing the president's apartments, the various government offices, the chamber of representatives, and the ambassadors' hall with full-length portraits of several Mexican patriots, headed by a magnificent one of Washington. To the government house are attached several courtyards and a botanical garden; this edifice, erected in 1698, stands upon the spot occupied by the palace originally constructed by Cortes for himself, and which, until its destruction by fire at the hands of the populace in 1692, had successively served as the residence of 50 viceroys. Facing the cathedral is the cabildo or city hall, in which is contained the merchants' exchange; and on the same side is the portal de los flores, an extensive arcade, similar to the portal de mercaderes, which flanks the W. side of the plaza, and before the numerous and showy shops in which are spread to view on stalls endless varieties of filigree work in gold and silver, and other ornamental articles. On the plaza de Santo Domingo are three noteworthy edifices: the convent of the same name, remarkable for its handsome chapel, the old inquisition building, now the school of medicine, and the custom house. Other celebrated churches of Mexico are those of San Fernando, Loreto, Encarnacion, Jesus Maria, the chapel of Santa Teresa with a superb cypress in marble, and that of the Concepcion, all celebrated for the beauty of their architecture or their gorgeous and costly decorations. Mexico includes 14 parishes. Eight convents and 21 nunneries which were suppressed by President Juarez's reform law of July 12, 1859, have since been converted into school houses. In the mint were coined, from 1690 to 1853, $1,702,650,087; and the gold and silver coinage in 1867 amounted to $4,304,313 95. The national museum, on the N. side of the government palace, contains one of the finest and most extensive collections of paintings in America; and in the school of fine arts are preserved rare specimens of sculpture, painting, engraving, and design. In the courtyard of the national museum are exposed a circular monolith calendar attesting the high degree of civilization attained by the Toltecs, whose year almost exactly coincided with the Julian year; a ponderous statue of Huitzilopochtli, the Aztec god of war, bearing no semblance of human form or feature, but being a fantastic and heterogeneous group-

The Cathedral.
or death's heads, hands interlaced, snakes, feathers, &c.; a sacrificial stone; and a num-
ber of idols and other minor relics from va-
rious parts of the country. Two other hand-
some piles are the post-office and the hotel Tur-
bide, the latter having been for a short sea-
son the residence of Agustin L. The prin-
cipal promenade is the Alameda, shaded with
stately beeches, embellished with nine foun-
tains and eleven glorietas or summer houses,
and tastefully laid out in spacious walks. This
is a favorite resort on Sunday mornings, when
a regimental band plays for two hours. Other
passos are those of the Viga, extending along
the canal of that name, on which has been
erected a colossal bust of Guatemozin, the last
emperor of the Aztecs; and the paseo de
Bucareli, with a superb bronze equestrian
statue of Charles IV., modelled by Manuel
Tolsa.—In 1874 Mexico had 218 public schools,
77 of which were for females and 48 for both
sexes; the average attendance was 16,915.
These schools include the escuela preparatoria,
formerly the college of San Ildefonso (under
the rectorship of Señor Lermo de Tejeda till
1872), the schools of jurisprudence, medicine,
agriculture, engineering, fine arts, commerce,
arts and trades, deaf and dumb, and those sus-
tained by the municipal government and the
Lancastorian company, one or two by private
individuals, and a number by benevolent socie-
ties. The school of engineering has a fine col-
clection of specimens in natural history, and
a cabinet of mineralogy. The philharmonic so-
ciety, with a subsidy from the government,
supports a musical conservatory for both sexes.
There are also a seminary for the education
of priests, a school for the blind, and a night
school for adults. The public has access to
two libraries: the gran biblioteca nacional,
with upward of 100,000 volumes and manu-
scripts, and the biblioteca popular del cineo de
Mayo. There are 21 societies, scientific, artis-
tic, or commercial, including the geographical
and statistical society, and the association
of natural history. The theatres are much
more numerous than beautiful or commodious,
and with a circus are the only public places of
amusement in Mexico, the bull ring having
been demolished in 1874. The city supports
five hospitals, an insane asylum for males and
one for females, and a house of correction.
Two institutions of comparatively recent foun-
dation take care of young children during the
day, in order to leave their mothers at liberty
to work. The principal cemeteries hitherto
in use are now closed, being within the muni-
cipal limits; their place has been supplied by
the general cemeteries of La Piedad and Campo
Florida, the French, and the Protestant ceme-
teries. There are four very good markets, con-
stantly stocked with an abundance of the pro-
ductions of all the zones. All the fruits and
vegetables generally regarded elsewhere as deli-
cacies here come to market every day in the
year, and the supply of tropical fruits is inex-
haustible. Most of the vegetables and fruits
are grown upon the chinampas or so-called
floating islands on Lake Tezcuco, and brought
to market in boats by the canal de la Viga;
and prodigious quantities of flowers of most
brilliant colors and most fragrant odors are
daily brought to the city in the same way.
A new abattoir was erected in 1874, at a cost
of $500,000. The water supply reaches the town
by two aqueducts of monumental proportions,
one bringing agua gorda (thick water) from
Chapultepec, and the other agua delgada (light
water) from the southwest.—The climate is
mild, equable, and very salubrious; the mean
annual temperature is 70°. The more com-
mon diseases are pneumonia, dysentery, and
diarrhoea, and the average mortality is about
8 per cent of the population.—The chief oc-
cupations of the inhabitants are agriculture,
The manufacture of paper, earthenware, cot-
ton, woolen, and silk fabrics, the preparation
tof tobacco, and the importation of the various
products of the adjoining states and of manufac-
tured goods, wines, &c., from Europe, the
United States, and the West Indies, especially
the island of Cuba. The chief financial insti-
tutions are the bank of London, Mexico, and
South America, and numerous private banking
houses; a government pawn office, with branch-
es in several parts of the city; and 18 lotteries,
with an aggregate risk capital of nearly $2,-
500,000, and an annual award of $150,000 to the
central government. The chief places of interest in the vicinity are Guadalupe
Hidalgo, Tlaipan, San Angel, Mixcoac, Coyoa-
can, Atzcapozalco, Churubusco, Tacuba, Tacu-
baya, noted for its handsome private houses,
and Papotla and Chapultepec. Almost all
these places are reached by railway (with steam
or horse power) or omnibus from Mexico, which
is likewise connected by railway with Puebla,
Orizaba, Cordova, and Vera Cruz; and a line
is in process of construction to Toluca.—Mex-
ico owes its chief historical interest to its situa-
tion on the site of an ancient city, the capi-
tal of the Montezumas. The Aztecs or ancient
Mexicans, after their migration from the north,
wandered for a long time in the Mexican val-
ley, till in 1325 they halted on the S. W. bor-
ders of the lake of Texcoco, and there beheld
an eagle perched on the stem of a nopal, and
devouring a serpent. An oracle having an-
nounced the omen as auspicious, and as indic-
ting the site of their future metropolis, they
founded it upon the islets of Lake Tezcuco,
calling the place Tenoctitlan, "nopal on a
stone," in allusion to the omen. Its name of
Mexico was subsequently derived from that of
their god Mepiti. By the middle of the 15th
century the city had become large and pro-
perous, and in place of reeds and rushes were
substituted stone and lime; and when on the
evening of Nov. 7, 1519, its long lines of glit-
tering edifices first met the eyes of Cortes
and his followers, it looked, says Prescott,
like a thing of fairy creation rather than the
work of mortal hands. On their entry into Mexico next day the Spaniards found fresh cause for admiration, in the grandeur of the city and the superior style of its architecture. The city was 9 m. in circumference, and the number of its houses was about 60,000, and of inhabitants probably 500,000. Though a few of the streets were wide and of great length, most of them were narrow and lined with mean houses. The large streets were intersected by numerous canals crossed by bridges. The palace of Montezuma, near the centre of the city, was a pile of low irregular stone buildings of vast extent. Another palace, assigned to Cortes on his entrance into the city, was so large as to accommodate his whole army. But the most remarkable edifice of the city was the great Teocalli or temple, completed in 1486. It was encompassed by a stone wall about 8 ft. high, ornamented on the outer side by figures of serpents in basso-rilievo, and pierced on its four sides by gateways opening on the four principal streets. Over each gate was an arsenal, and barracks near the temple were garnished by 10,000 soldiers. The temple itself was a solid pyramidal structure of earth and pebbles, coated externally with hewn stones. It was square, its sides facing the cardinal points, and was divided into five stories, each of which receded so as to be smaller than that below it. The ascent was by a flight of 114 steps on the outside, so contrived that to reach the top it was necessary to pass four times round the whole edifice; and the base of the temple is supposed to have been 300 ft. square. The summit was a large area paved with broad flat stones. On it were two towers or sanctuaries, and before each was an altar on which a fire was kept continually burning. The top of this remarkable structure commanded a superb view of the city, lake, valley, and surrounding mountains. The police of the city was efficient and vigilant; and 1,000 men were daily, employed in watering and sweeping the streets. As the lake that surrounded the city was extremely brackish, pure water for the supply of the people was brought by an aqueduct from the neighboring hill of Chapultepec, where Montezuma had a summer palace surrounded by vast and magnificent gardens. In the final siege by the Spaniards, Cortes, despairing of otherwise subduing a place where every house was a fortress and every street was cut up by canals, reluctantly determined to destroy the city, which he calls "the most beautiful thing in the world." With the aid of his multitudinous Indian allies, whose hatred of the Aztecs led them to work with zeal, in a few weeks seven eighths of the city was levelled to the ground, and the canals filled with the rubbish. Soon after the termination of the siege Cortes began to rebuild the city on its present plan, assembling for the work a host of Indians, estimated by a Mexican writer at 400,000. During its occupation by the Spaniards, from 1521 to 1821, the most remarkable events in the local history of Mexico were five great inundations in 1558, 1560, 1604, 1607, and 1639, caused by the overflowing of the neighboring lakes. To prevent the recurrence of these inundations a great drain was dug through the hill of Nochistango, by which the waters of the river Cuautitlan were led out of the valley instead of falling into the lake of Tezutco. This work, which was completed in 1789, after more than 100 years of labor, is about 12 m. long, from 100 to 150 ft. deep, and between 200 and 800 ft. wide. Since the establishment of Mexican independence, the city has been the scene of several revolutions and insurrections, and a number of important battles have been fought in the vicinity, the most noted being those of Contreras and Churubusco, Aug. 20, 1847, and of Chapultepec, Sept. 13, fought between the American army under Gen. Scott, and the Mexican army under Gen. Santa Anna. After this battle the Americana occupied the city, and held it until the ratification of the treaty of Guadalupe Hidalgo, in May, 1848.
months, and there are very few good harbors. Havana, Mobile, and Galveston are the most important ports; and Campeachy and Vera Cruz are two of the principal shipping points. —The depth of the gulf is believed not to exceed three quarters of a mile. The reefs and shoals of the N. shores of Cuba and about the Florida keys render the passage into the Atlantic exceedingly intricate, but elsewhere there are few banks; the only large one lies about lat. 27° N., lon. 86° W., 200 m. S. of Cape San Blas. Besides the N. E. and S. E. trade winds which prevail in the gulf, it is visited by violent northers, which occur at intervals from October to May; in some years they terminate in April. The most remarkable phenomenon connected with the gulf of Mexico is the Gulf stream (see Atlantic Ocean), which enters it by the channel of Yucatan, passes around it, and flows out by the Florida channel. The temperature of the gulf water is 8° or 9° higher than that of the Atlantic ocean in the same latitude. In its centre are found large quantities of fucus natans or gulf weed, floating in parallel lines from S. S. E. to N. N. W.

MEYENDORFF, a Russian family, originating in Saxony, and including among its members Pope Clement II. They settled in Livonia about 1200, and became Swedish barons in the 17th century. Subsequently they acquired distinction in the Russian military and diplomatic service, especially Peter (1796–1865), who was ambassador in Vienna in 1850, and one of the negotiators of the convention of Olmütz; Alexander (died in 1865), a geographer and geologist, who promoted and accompanied in 1840 Murchison's and Verneuil's exploration of northern Russia; Geone (died in 1863), who published Voyage d'Orembourg à Boukhara (Paris, 1826); and Felix (died in Carlsruhe, Jan. 16, 1871), who in 1837 married the princess Olga, a daughter of the late prince Michael Gortlitz. He became secretary of legation in Berlin, and in 1864 charged d'affaires in Rome. During his stormy interview with the pope, Jan. 1, 1866, resulting in a temporary rupture between the cabinet of St. Petersburgh and the holy see. Subsequently he was chargé d'affaires at Carlsruhe.

MEYER, Felix, a Swiss painter, born in Winterthur, canton of Zürich, Feb. 6, 1653, died May 28, 1713. He studied painting under Ernens in Nuremberg, and gained reputation by his views of Swiss scenery. He was employed throughout Germany by princes and others in ornamenting their apartments in fresco. He also etched several plates of landscapes from his own designs.

MEYER, Johann Georg, known as Meyer von Bremen, a German painter, born in Bremen, Oct. 28, 1813. He studied at Düsseldorf, and settled in Berlin in 1832. He acquired celebrity as a painter of childhood, and his works are popular in England, France, and the United States. Many of them have been engraved.
in Darmstadt Meyerbeer composed an oratorio, *Gott und die Natur*, which was received with great favor by the grand ducal family, and caused him to be appointed composer to the court. After about two years' study he set out on a tour through Germany, in company with Vogler, under whose auspices he produced his opera "Jephthah" at Munich in 1812. This, on account of its scientific precision, gave so much satisfaction to his teacher, that he pronounced him to have reached the climax of musical science, and handed him his official diploma as "maestro." But "Jephthah" had no elements of popularity, and was considered a failure. Discouraged by this reception, and at the same time impressed by the genius of Hummel, Meyerbeer now made his début as a pianist at Vienna, with brilliant success. The court of Vienna commissioned him to compose an opera, and he soon produced *Die beiden Khaliylen*, which was no more successful than "Jephthah." Both operas being totally opposite to the popular taste, which at that time was delighted with the productions of Rossini and Italian music generally. His friend Salieri prevailed upon him to visit Italy. Meyerbeer on his arrival there witnessed the performance of Rossini's "Tancred," and his enthusiasm for the Italian school now became as great as his aversion for it had formerly been. He began to imitate the Italian style, and composed in rapid succession a series of operas, which were almost all favorably received. His *Rinaldo e Costanza* was performed in Padua in 1818; his *Semiramide riconosciuta*, after Metastasio, in Turin in 1819; and his *Emma di Resburgo*, based upon the same subject as Méhul's "Helen," in Venice in 1820, in the same season with Rossini's *Eduardo e Cristina*, the productions of the German and Italian masters receiving the same share of enthusiastic applause. *Emilia" was translated into German and performed in the principal opera houses of his native country. In the mean time it had been successfully received by enthusiasm by the fastidious audiences of the Scala in Milan, and paved the way for the favorable reception there of his next opera, "Margaret of Anjou" (1822), in which Levasseur made his début on the Italian stage. This was succeeded by *L'Ecole di Granata* (1823), the principal parts of which were written for Lablache and Pisaroni. But the procrastination in its performance, which did not take place before the carnival of that year, proved fatal to its reception. The first act was missed, and the second would have shared the same fate but for a duet admirably sung by Lablache and Pisaroni. Subsequently the opera proved successful. "Almanzor" was also composed in 1823, and intended for the opera of Rome; but owing to the illness of Carolina Bassi, who was to take the principal part, it was never brought out. The *Crociato* was given in Venice at the end of 1823, and at the close of the performance Meyerbeer was called before the curtain and crowned amid the plaudits of the audience. He now made the tour of the different Italian cities, to attend personally to the production of his works. The *Crociato* may be taken as the best and most individual of his productions up to that time, the style of which had been marked by a successive improvement, and formed a turning point in Meyerbeer's career. M. de la Rochefoucauld invited him to Paris (1826), where the *Crociato* was received with considerable favor, and Paris was henceforth his headquarters. In 1826 he composed *Robert le diable*, which he sold in July, 1830, to M. Lubbert, director of the grand opera, and which made the fortune of his successor, M. Véron. After many rehearsals it was at length brought out in November, 1831. The excitement it created was unparalleled in the history of the Parisian stage. It combined in a singular degree oriental gorgeousness, German thoughtfulness and French vivacity, and Italian brilliancy, and exhibited a breadth and depth of talent for which the preceding works of the composer, with the exception of some parts of the *Crociato*, had hardly prepared the public. The enthusiasm which greeted it in Paris was shared by nearly all Europe, but it found perhaps more admirers in Germany and France than in other countries, and never fully received recognition in England. The Germans especially were fascinated by an opera which in some respects reminded them of Goethe's "Faust," and which combined in so remarkable a degree the convivial, picturesque, pathetic, and supernatural elements. The most popular airs were soon transferred from the stage to the streets, and sung in the taverns. Jenny Lind won her brightest laurels in London by her personification of Alice, and Formes invested Bertram with an intellectualism almost equaling that of Goethe's Mephistopheles. The melodies of "Robert," the best produced by Meyerbeer, are in the main formed upon the style of Rossini, with certain characteristics from Weber's supernaturalism and the developed orchestration of the period, with the extensions proper to a long subject fully handled. The keen and subtle intellectuality of the composer is revealed throughout the whole work in his effort to make it in every sense acceptable to Parisian audiences. Hence his adoption of the extended musico-dramatical form, so popular in France; his attention to effective contrasts and sequences, which the French dramatists and lyrical composers treat with such consummate skill; his introduction of a vast range and variety of scenic accessories; the sonority of the orchestra, so much insisted upon at the grand opera; and the selection of a libretto by Scribe, which rivets the attention of the audience through the whole of five long acts, without for a moment abating in interest. Meyerbeer reached the climax of his fame by his opera *Les Huguenots*. The admiration which this work elicited on its first appearance.
MEYERBEER

in Paris in March, 1838, has not yet diminished; and even in Berlin, where his productions had been subjected to the adverse criticism of jealous rivals and of antagonistic schools of music, all depreciating voices were hushed by the "Huguenots," and the friends and foes of the composer became for the first time unanimous in their admiration of his genius. The dramatic character of the "Huguenots" is not surpassed by any work of the lyrical stage, and the strife between the great religious parties in France was never before portrayed with such graphic power and thrilling effect. The "Huguenots" is, above all, to be regarded as one of the first of the operatic achievements which derive their inspiration from the records of history; and it contributed to inaugurate the era of the lyrico-historic drama, in which the greatest effects that the musical and dramatic stage and its accessories are capable of are used to illustrate the most momentous conflicts of mankind. Like most great works, those of Meyerbeer required time in their elaboration, and 13 years elapsed before his next opera, Le prophète, was ripe for performance. It appeared in 1849, and at once took a high place as a worthy successor of the "Huguenots." Although much less imposing in its historic groundwork and in its general effect, it shows the same largeness of musical and artistic treatment; and as a lyrical drama it derives great beauty from the admirable manner in which the maternal love of Fides is placed in contrast with the religious frenzy of her son, the prophet of Leyden. The scores in this opera, as in Meyerbeer's other works, are wonderful in their elaboration, and may be commended to students for their careful dramatic portraiture, in which the orchestra is made to echo and anticipate the characterization of the scene. The extraordinary labor bestowed upon the mise en scène of the "Prophet" has been deemed superfluous by several critics, who regard this excessive elaboration of external effects as derogatory to the genius of the composer and to the intrinsic merits of his works. The "Prophet" was followed by Pierre le Grand (L'Étoile du nord, 1854), and "Dinorah" (Le pardon de Ploermel, 1855). The former of these shows the versatility of the author, though its success cannot be compared with that of its great predecessors; "Dinorah," which treats a rustic and pastoral theme, is variously criticised in Europe, and unfavourably as regards melody. Meyerbeer published a great number of miscellaneous musical compositions, among which are Le camp de Silésie, an opera produced at Berlin; Stabat, Miserere, a Te Deum, eight of Klopotock's canticles, a number of cantatas, many songs for solo voice with pianoforte accompaniment, and some minor orchestral works. He wrote also the incidental music for his brother's drama of Struensee. He was for many years engaged upon the opera L'Africaine. This work was elaborated with the same indomitable care that the composer had bestowed on Robert le diable and Le prophète, and exhibits the same characteristics of its author, a profound knowledge of all the elements of effect and labored detail rather than inspiration. Although it was completed several years before his death, he delayed its production, waiting to find a prima donna who should satisfy his ideal of Selika. It was brought out in Paris in April, 1865, and in New York in December of that year.—See Meyerbeer et son temps, by H. Blaze de Bury (Paris, 1860), and Giacomo Meyerbeer, sein Leben und seine Werke, by H. Mendel (Berlin, 1868).

MEYERHEIM. I. Friedrich Eduard, a German painter, born in Dantzic, Jan. 7, 1808. He studied at Berlin, and became a professor in the academy there. Many of his genre pictures, chiefly relating to the life of the peasantry, have been engraved, his "Altenburger in the Corn Field" by himself. His best known picture is a little milkmaid sitting at the roadside counting her earnings, of which there is a chromo-lithograph. II. Wilhelm Alexander, his younger brother, excels as a painter of horses, battles, and landscapes, and as an engraver. He exhibited in 1858 "Prince Frederick Charles at Liebenau" and "The King in the Battle of Sadowa." III. Eduard Franz, son of Friedrich Eduard, born in Berlin in 1838. He studied under his father, and spent some time in Düsseldorf. Among his genre pictures are "The Polisher of Arms" (1858), "Children with Cats" (1859), "The Love-sick Girl" (1866), and Dornröschen and Schneewittchen (1870). IV. Paul Friedrich, brother of the preceding, born in Berlin in 1842. He studied under his father, and spent over a year in Paris. He has produced many fine genre animal pictures, among others "The Serpent Tamer in the Menagerie," "The Goat Market," and "The Tribunal of Apes." He has made designs for illustrated works, including Reineke Fuchs (1870).

MEYERS, a S. county of Dakota, bordering on Nebraska, recently formed, and not included in the census of 1870; area, about 2,850 sq. m. It is drained by the Keya Paha and affluents of White river. The surface consists of undulating prairies and plains.

MEYR, Melchior, a German author, born near Nördlingen, June 28, 1810, died in Munich, April 22, 1871. He studied at Anspach, Augsburg, Munich, and Heidelberg, became known as a poet in 1835 and as a prose writer in 1838, resided in Berlin from 1840 to 1852, and afterward chiefly in Munich. His principal works are his Erzählungen aus dem Ries (2 vols., Berlin, 1856–60; 2d ed., Leipsic, 1868), supplement, Hanover, 1870; Gott und sein Reich (Stuttgart, 1860; sequel, Emilie, 1863); Gespräche mit einem Grobian (Leipsic, 1866; 2d ed., 1867); Duett und Ehre, a novel (2 vols., 1870); and the posthumous Gedanken über Kunst, Religion und Philosophie, edited by Max count von Bottmer and Moritz Carriere (Leipsic, 1874).
MEZIERAY, François Endes de, a French historian, born at Ry, near Argentan, in 1610, died in Paris, July 10, 1683. He served for two campaigns as commissary in the army, after which he wrote his Histoire de France (3 vols., 1643–51). He received from the king the title of historiographer royal, and a pension of 4,000 livres, which he forfeited in 1668 by publishing an abridgment of his Histoire containing severe reflections on French taxation. He was also elected a member of the French academy, and in 1675 its perpetual secretary. His history of France has been continued down to 1830 (Paris, 1839).

MEZIÈRES, a fortified town of France, capital of the department of Ardennes, on a peninsula formed by the confluence of the Meuse and Vence, and on a branch of the Eastern railway, 125 m. N. E. of Paris; pop. in 1866, 5,818. It has an arsenal, an important magazine, and manufactories of powder and marine projectiles. In the Franco-German war it capitulated in January, 1871.

MEZIÈRES, Alfred, a French author, born at Rehon, department of the Moselle, Nov. 19, 1826. Like his father, Louis Mézières (born in Paris, Nov. 28, 1793), he has distinguished himself by his writings on English and Italian literature, and he has been since 1864 professor of foreign literature at the Sorbonne. On Jan. 29, 1874, he was elected to the French academy. His Prédications et contemporaires de Shakespeare obtained a Montyon prize in 1864, and his Pétrarque, written from new documents, received one in 1868. In 1873 appeared his Goethe, les œuvres expliquées par la vie: Dernières années.

MEZQUITE (Aztec, mezquitl), the Mexican name for prosopis glandulosa, which was formerly placed in the genus algarobia, a tree of the mimosa suborder of the leguminose. The mezquite seldom grows more than 30 or 40 ft. high, and when well developed has a rounded head; but owing to the injuries caused by lizards and the Texas rats, the trunk and branches are frequently irregular and distorted. In its foliage it greatly resembles the honey locust (Gleditschia), having usually twice-pinnate leaves, which are glandular where the leaflets join the common petiole, and have a pair of strong spines at their insertion upon the stem; the leaflets are narrow, somewhat curved, and an inch or more in length; the small greenish-yellow flowers are crowded in dense axillary spikes 3 to 4 in. long; the pod or bean is 6 in. or more in length, straight or curved, compressed, and somewhat constricted between the numerous seeds. The tree has a wide, rapid, being found as far north as the Canadian river and extending far south into Mexico; it makes its appearance a short distance from the coast in western Texas, and is the most abundant tree as far westward as the Colorado and the gulf of California; it is exceedingly variable, sometimes appearing as a large shrub forming dense thickets, which from the abundance of spines are impassable, and at other times growing singly with well developed heads, and when viewed from a distance appearing like an apple orchard, so uniform are the trees in size. Were it not for the mezquite, large tracts in Arizona and northern Mexico would present still greater difficulties to the traveller than they do, as this tree there affords the sole supply of fuel and forage. The wood is very hard, fine-grained, dark reddish brown in the heart wood, and is sometimes used by the Mexicans for furniture, but it is difficult to get pieces large enough to be valuable for lumber; its durability is probably not inferior to that of the locust. As fuel the mezquite has no superior; it makes a hard sonorous coal, a fire of which is almost as intense as one of anthracite; travellers across the desert country where it abounds rely upon it for fuel, the roots being found almost everywhere; where frequent fires destroy the trees the roots remain untouched, throw up a yearly growth of small stems, and thus continue to increase in size, while the growth above ground is destroyed every year or two; it very often happens that a clump of bushes with stems only an inch or two in diameter will lead to the unearthing of roots as large as one's leg. At a profitable silver mine in the state of Chihuahua, visited by the writer several years ago, the smelting of the ore was effected entirely with mezquite roots as fuel. The pods, or beans as they are generally called, at a certain state of maturity contain a sugary pulp, which often has a very pleasant flavor, and when quite ripe is mealy, dry, and highly saccharine, but with a mawkish taste that is to most persons disagreeable, though the Mexicans and Indians are fond of it; the dried pods are beaten in a mortar, and when the seeds and other matters are separated by
sifting a sugary meal is obtained, which is used for sweetening pinole (see Maiz), and otherwise as a substitute for sugar. The great value of the pods is as a food for horses and cattle, which eat them with the greatest avidity; in many places entirely destitute of grass the mezquite beans are most welcome to the traveller. It has been proposed in Utah and Colorado to employ the mezquite as a hedge plant, to which its thorny character would adapt it; but its great liability to be attacked by borers makes the experiment doubtful. The tree exudes a gum resembling gum arabic. (See Gum.)—The plant called by Americans the screw-pod or screw-bean mezquite, and by the Mexicans tornillo, is Prosopis pubescens, to which the name strombocarpa has also been given; it has a similar general appearance to the mezquite, but is more slender; its spines are smaller, and its leaves pubescent on the under surface; the pod is curiously twisted to form a close spiral about 2 in. long; this also contains a sweetish pulp, but is less valuable as a food for animals than the mezquite. The tree, which is found from Utah and Nevada southward, is less abundant than the mezquite, and generally prefers a moister soil.

MEZZOFANTI, Giuseppe Gasparo, an Italian linguist, born in Bologna, Sept. 17, 1774, died in Rome, March 15, 1849. He was educated for the church, and was ordained in 1797. He had an extraordinary memory, and before the close of his university career had mastered the Latin, Greek, Hebrew, Arabic, Coptic, Spanish, French, German, and Swedish languages. At the age of 23 he was appointed professor of Arabic at Bologna; but on the annexation of that city to the Cisalpine republic, he was removed from his professorship for refusing to take the oath to the new constitution. After the conclusion of the concordat between Pius VII. and Napoleon, Mezzofanti was restored to the university, and named professor of oriental languages. The suppression of his professorship in 1808 left him mainly dependent on private tuition for his own support and that of his sister's children. The wars of which northern Italy was so long the theatre had afforded him many opportunities of extending his knowledge as a linguist. In the hospital of Bologna, to which he had attached himself as volunteer chaplain, were invalids from most of the countries of central and eastern Europe; and while administering to them he acquired a knowledge of their respective languages. In 1812 he was appointed assistant librarian, and in 1815 head librarian of the university of Bologna. After the conclusion of peace, his reputation as a linguist rapidly extended. In 1817 he could read 20 languages and write 18. Lord Byron, whom he is said to have beaten in talking English slang, pronounced him a monster of languages, a Brieure of parts of speech, and a walking polyglot. Having gone to Rome in 1831 as one of a deputation sent by the Bolognese to congratulate Gregory XVI. on his election, he was induced by the pope to accept a prebend in the church of St. John Lateran, and soon afterward a canonry in St. Peter's. In 1838 he succeeded Angelo Mai as chief keeper of the Vatican library, an office which he held till 1888, when he was made a cardinal. During his residence in Rome he gained a knowledge of Irish, Welsh, Lappish, Sanskrit, Persian, Georgian, Armenian, Chinese, and several African tongues. His familiarity with the dialectical varieties and local idioms of the principal languages, as well as with their respective literatures, and his power of passing from one to another in conversation, were almost incredible. At the time of his death he is said to have been acquainted with 114 languages. Mezzofanti, though a learned theologian and canonist, is almost unknown as an author; his only published work being a panegyric "Memoir of Father Emanuele da Ponte," a brother professor (Bologna, 1820). His life has been written by Charles William Russell, D. D., principal of Maynooth college (London, 1858; 2d ed., 1863).

MIAKO. See Kioto.

MIALL, Edward, an English journalist, born in Portsmouth in 1809. He was educated in the Protestant dissenters' college at Wymondley, Herts, and for several years officiated as an Independent minister at Wars and Leicester. In 1841 he established the "Nonconformist" newspaper in London, in the interests of the "anti-state-church" party, and is still its editor and proprietor. He was elected to parliament for Rochdale in 1852, but lost his seat in 1857, and was returned for Bradford in 1869. In parliament he has been a persistent advocate of manhood suffrage and other popular reforms. He has published "The Nonconformist's Sketch Book" and "Views of the Voluntary Principle" (1849); "Ethics of Nonconformity" (1849); "The British Churches
in relation to the British People" (1849); “Bases of Belief” (1853); “Title Deeds of the Church of England to her Parochial Endowment” (1863); and “An Editor off the Line, or Wayside Musings and Reminiscences” (1865).

MIAMI, a river of Ohio, which rises in Hardin co., flows S. and S. W. for a distance estimated at 150 m., passing Troy, Dayton, and Hamilton, and falls into the Ohio river at the S. W. corner of the state, 20 m. W. of Cincinnati. It passes through a picturesque and fertile country, is rapid, and admits of navigation for only a portion of its length. Its principal branches are the West branch and the Mad and Whitewater rivers. The Miami canal runs along the river for about 70 m., and together they furnish extensive power for manufacturing. —This river is sometimes called the Great Miami, in distinction from the Little Miami, which rises in Clark co., and by flowing S. W. 100 m., nearly parallel with the former, falls into the Ohio 6 m. E. of Cincinnati.

MIAMI. I. A W. county of Ohio, intersected by the Miami river and drained by its branches; area, about 400 sq. m.; pop. in 1870, 82,740. The surface in the E. part is rolling, in the W. more level, and the soil is very fertile. It is intersected by the Miami and Erie canal, and by the Pittsburgh, Cincinnati, and St. Louis and the Dayton and Michigan railroads. The chief productions in 1870 were 858,886 bushels of wheat, 1,200,096 of Indian corn, 374,415 of oats, 71,804 of barley, 82,521 of potatoes, 40,221 of flax seed, 206,704 lbs. of flax, 71,529 of tobacco, 55,181 of wool, 468,132 of butter, and 11,551 tons of hay. There were 6,136 horses, 6,508 milch cows, 7,796 other cattle, 16,148 sheep, and 19,414 swine; 1 manufactory of agricultural implements, 11 of brick, 18 of carriages and wagons, 6 of lime, 2 of machinery, 9 of marble and stone work, 3 of linsseed oil, 5 of sash, doors, and blinds, 3 of woolen goods, 3 iron foundries, 18 flour mills, 8 saw mills, 5 tanneries, 4 distilleries, and 4 breweries. Capital, Troy.

II. A N. county of Indiana, intersected by the Wabash and Eel rivers; area, 384 sq. m.; pop. in 1870, 91,052. It has a generally level surface, with elevations near the streams, and a fertile soil. It is intersected by the Toledo, Wabash, and Western, and several other railroads. The chief productions in 1870 were 484,817 bushels of wheat, 417,930 of Indian corn, 100,757 of oats, 61,687 of potatoes, 66,043 lbs. of wool, 372,457 of butter, and 17,560 tons of hay. There were 6,609 horses, 5,111 milch cows, 7,156 other cattle, 20,706 sheep, and 20,794 swine; 5 manufactories of agricultural implements, 18 of carriages, 6 of saddlery and harness, 9 of cigars, 2 of woolen goods, 3 iron foundries, 18 flour mills, and 1 brewery. Capital, Peru.

III. An E. county of Kansas, bordering on Missouri, and intersected by Osage river; area, 576 sq. m.; pop. in 1870, 11,725. It is traversed by the Missouri river, Fort Scott, and Gulf railroad, and by the Osage division of the Missouri, Kansas, and Texas line. The surface is undulating and the soil肥沃. The greater portion of the county is prairie, but there is considerable woodland. The chief productions in 1870 were 54,596 bushels of wheat, 764,145 of Indian corn, 268,500 of oats, 71,342 of potatoes, 11,243 lbs. of wool, 240,323 of butter, and 14,147 tons of hay. There were 4,913 horses, 4,774 milch cows, 7,865 other cattle, 3,922 sheep, 7,756 swine, and 8 saw mills. Capital, Paola.

MIAMIS, an Indian tribe of the Algonquin family. They comprised the Ouatenon or Wea, Peanguchia or Piankeshaw, Pekopika, Kilatak, and other bands. They were found by the French in 1658 near Green bay, and in 1870 Alonzo found a large village at the head of Fox river, under Tetonchoua, a chief who had a body guard and was treated with a respect unusual in the northern tribes. They then numbered 8,000 warriors, according to some accounts, lived in mat houses within a palisade, and were brave, civil, and well disposed. A large body soon after congregated on the St. Joseph's river. In 1833 they and their kindred the Illinois were attacked by the Iroquois; they maintained the war vigorously, although at the same time fighting the Sioux on the west. The presence of some French traders among the Sioux in 1686 brought them into collision with the French, and they nearly burned Nicolas Perrot at the stake. They sent a detachment to swell Denonville's army, but began then to be very restless, joined the Iroquois against the Hurons, menaced the Chippewas, and opened intercourse with the English. Their losses in war were heavy; a whole village was carried off by the Sioux in 1700.

In 1705, trouble having arisen between the Miami and the Ottawas at Detroit, the former attacked the latter, and a general engagement ensued, the French officers having precipitated the war. Cadillac finally marched against the Miami in 1707, but made a hollow peace which increased their insolence. They had at this time retired temporarily from Chicago and from the St. Joseph's river. In 1751 the Miami were on the St. Joseph's and the Miami, and the Wea band on the Wabash or Ohio. When the final struggle between England and France approached, they wavered; they attacked the Senecas, but met the English colonists at Lancaster, plundered the French posts, and allowed an English fort to be erected on their lands. In 1751 the French attacked them, killing several English and Indians. After the fall of the French power they prevented the English troops from crossing their country, but finally made peace, though they joined Pontiac and captured the British forts Miami and St. Joseph's. During the revolution they sided with England; but when Clarke reduced Illinois and took Hamilton prisoner, and their own towns were ravaged, they made peace. A
Miantonomoh, a sachem of the Narragansetts, nephew of Canoniens, whom he succeeded in 1636. He maintained friendly relations with Massachusetts, and in 1637 aided in chastising the Pequots. Sequossaw, one of his chiefs, having been attacked in 1642 by Uncas, the Mohogan, Miantonomoh with the consent of the governor of Hartford marched against Uncas with nearly 1,000 men, but was defeated and taken prisoner at Norwich. The victor took his captive to Hartford and left his fate in the hands of the commissioners of the United Colonies, who advised his execution. He was tomahawked in 1645 on Sachem's plain, the field where he was defeated. A monument was erected on the spot in 1841.

Miallis, Andros, a Greek admiral, born in the island of Negropont about 1770, died in Athens, June 23, 1835. His father, Demetrios Vokos, owned a felucca (Turk. miaul), and put his son in charge of it, whence his surname. The latter settled at Hydra, where successful commercial enterprise gave him influence. He joined the Greek revolution in 1821, and in 1822 became commander-in-chief of the national fleet. In the same year he defeated the Turks at Patras (March) and Spezzia (September); and in May, 1825, he burned Ibrahim Pasha's squadron at Modon, and inflicted further damage on the enemy's fleet. In 1827, soon after Lord Cochrane's appointment as head of the navy, he retired from the service; but Capo d'Istria reinstated him and placed him also in charge of the port of Poros. After demonstrating in vain against the neglect of the navy, he joined the insurrectionary government at Hydra in 1831, and burned the Greek ships at Poros (Aug. 13), to prevent them from being seized by the Russians. He was arraigned for treason by Capo d'Istria, whose death (Oct. 9, 1831) put an end to the proceedings. In the following year Miallis was placed at the head of all the naval stations in the Archipelago. In 1832 he was a member of the deputation sent to Munich to offer the throne of Greece to Otho. Shortly before his death he was made vice admiral.—His son Athanarios was prime minister of Greece from 1855 to 1862, and his administration contributed largely to the overthrow of King Otho. He died in Paris in May, 1867.

Mica (Lat. microe, to sparkle), in mineralogy, the name of a group of the silicates, distinguished by their remarkable lamellar structure, the elasticity of their laminae, and their half metallic lustre. The minerals crystallize in right rhomboidal prisms of 120°, which separate with the greatest facility in foliæ parallel with the base of the crystal. These may be subdivided till many thousand plates are required to make the thickness of an inch. They are found usually transparent, elastic, and tough. The colors are various; the most common are silvery white, grayish green, red, and black. The hardness of the mineral is 2 to 3: specific gravity 2.65 to 3.3. The different species are distinguished partly by their different optical characters as well as by their differences of composition. They present two axes of double refraction, which, in the species designated by Dana as muscovite, and commonly known as Muscovy glass, vary in apparent inclination between 44° and 75°; in the phlogopites, called also rhombic mica and magnesia mica in part, from 5° to 20°; and in
the biotites below 5°. Prof. B. Silliman, jr., observes that the muscovites are confined to granitic and other igneous rocks, and the plagioclase to granular limestone and serpentine. The former generally contain potash or lime, and but little magnesia, and the latter contain magnesia, and often but little alkali. The composition of the most common micas, according to Dufrénoy, is from 45 to 50 per cent. of silica, 32 to 38 of alumina, 10 to 15 of alkali (rarely soda), and 2 to 4 of fluororic acid. He considers the differences of composition too great to admit of any general formula. The micas are unisilicates, containing, besides silica and fluo-
rine, alumina, iron, magnesia, potash, lithia, rubidia, and cessa, the magnesia generally fail-
ing in the varieties found in the granitic rocks. Lepidolite is a species distinguished for its oc-
currence usually in granular masses made up of foliated scales of rose-red color, violet gray, yellowish, or whitish. Muscovite, the most familiar form of mica, is a constituent of gran-
ites, gneisses, schists and some other granite-like rocks. It is found both disseminated and in
veins, and in many of the stratified rocks it is an incidental constituent derived from the de-
struction of the original formations to which it belonged. The mineral is thus seen to be very generally distributed; but certain locali-
ties are distinguished for the production of large plates of it. In Siberia they have been found more than 3 ft. across, and they have been obtained of great size in Sweden and
Norway. This is also the case at Aeworth, Grafton, and Alstead, N. H.; and mica has been found in some of the other states and in
Canada sufficiently large to be quarried for
economical purposes. Mica is used mostly for
the doors of stoves and the sides of lanterns,
for which it is well adapted by its transparency
and refractory character. It has been used as
a substitute for window glass, and its tough-
ness recommends it for this purpose on board
vessels of war, in which the concussion from
the discharge of heavy guns might occasion the
fracturing of glass. It has also been used for
spectacles, optical instruments, and bronzing
powder, and is serviceable for holding
small objects for microscopic examination.
Very extensive mica mines were discovered in
Mitchell co., N. C., in 1867, which have since
been extensively worked. They had evidently
been worked centuries ago.

MICAH, one of the 12 minor prophets, who,
according to the testimony of his book (1. 1),
prophesied in the days of Jotham, Ahaz, and
Hezekiah, kings of Judah (about 759–688 B. C.).
He was a native of Moresheth of Gath. The
prophecy of Micah consists of two parts, the
first of which terminates with chapter w. It
begins with a sublime theophany, the descent
of the Lord to judge the nations of the earth,
and then denounces the iniquities of the two
Hebrew kingdoms, especially of the rulers and
prophets, predicts the captivity of Israel, the
fall of Judah, the destruction of Jerusalem, the
expatriation of the Jews, their return, and the
celebrity of the temple of Zion. Bloody wars are
seen in the perspective, and after many
calamities a ruler is seen to come forth from
Bethlehem (v.). The second part consists of
a discussion or controversy between the Lord
and his people. The authenticity of the book
is generally recognized; only the last two chap-
ters have been ascribed by Ewald to a young-
er prophet. The style of Micah is sublime and
vehement. Among the principal critical
writings on Micah are those of Caspari, Micha
der Moraviehe und seine prophetische Schrift
(Christiania, 1851); Hitzig, Kleine Propheten
(3d ed., 1868); and Ewald, Propheten (vol. i.,
1867).—Micah, or Micaiah, was also the name of
another prophet mentioned in the history of
Ahab, king of Israel (1 Kings xxii. 8–28).

MICALI, Giuseppe, an Italian archaeologist,
born in Leghorn about 1776, died in Florence,
March 28, 1844. He travelled extensively,
and devoted himself to archaeological studies.
His Italian translations and volumes of the
Storia degli antichi popoli italiani (3 vols.,
Florence, 1810, with a map and 67 plates; new
ed., 1831), won a prize, but incurred criticism,
which induced the author to remodel it under
the title Storia degl' antichi popoli italiani
(3 vols., 1832; 24 ed., Milan, 1836; enlarged
ed., 4 vols., Florence, 1843 et seq.; translated
into French by Raoul Rochette). It was fol-
lowed by Monumenti antichi, a volume con-
taining 120 plates (Florence, 1844).

MICA SLATE, a very abundant metamorphic
rock, consisting of mica and quartz, and some-
times feldspar, in which the mica predomi-
nates, and by its arrangement in parallel planes
gives to the aggregate a foliated structure.
It belongs to the mica-bearing series, of which
granite and gneiss are also members. Some
authors classify it under the same head with
mica schist, while others place it midway be-
tween mica schist and clay slate. What is
called mica schist sometimes contains numer-
ous garnets imbedded in it, when it receives
the name of garnet schist. It is prevalent
along the banks of the Tay and about Dunkeld
in Scotland, and also in the Blue Ridge moun-
tains in the United States.

MICHEL (Heb., who is as God), the angel
who had special charge of the Israelites as
a nation (Dan. x. 13, 21), who disputed with
Satan about the body of Moses (Jude 9), and
who with his angels carried on war with Sa-
tan and his angels in the upper regions (Rev.
xii. 7–9). The Jews regarded Michael as one of
the archangels, and the Christian church
early adopted this view. The representation
of Michael, sword in hand, conquering the
dragon, became a favorite symbol in the Ro-
man Catholic church. A festival of St. Michael
was introduced by Pope Felix III. (483–92),
and it was retained also in the Lutheran
church. Mohammedans regard Michael like-
wise as one of the archangels, and as guar-
dian angel of the Jews.

MICHAEL ANGELO. See Buonarroti.
MICHAUX and a day objections famous for neither Albens, civil peculiar tine. In 1745 he was appointed professor of philosophy at Göttigen. For nearly 20 years he edited the Göttinger gelehrte Anzeig. His principal works are: a translation of the Hebrew Bible; "Introduction to the New Testament," translated into English by Bishop Marsh; and Das Mosaische Recht (2d ed., 5 vols., Göttigen, 1776–80), translated into English by Dr. Alexander Smith, under the title of "Commentaries on the Laws of Moses" (4 vols., London, 1814).

MICHAELS, the fest of St. Michael the Archangel, Sept. 29. It is more celebrated for popular customs connected with it than for any peculiar religious observance. It was an old custom in England to mark the day by electing civil magistrates, perhaps in allusion to the analogy between the superintendence of magistrates and that of guardian angels, of whom St. Michael was reputed the prince. A more famous custom is that of eating roast goose, which has been traced at least as far back as 1471; and it is said that one of the strongest objections of the English commonalty to the reformation of the calendar was based on the confusion which would follow if Michaelmas day was not celebrated when stubble goose are in their highest perfection.

MICHAUD, Joseph, a French author, born at Albens, Savoy, June 19, 1767, died in Passy, Sept. 30, 1839. In 1791 he published a Voyage littéraire to Mont Blanc and the adjoining regions, followed by an oriental tale entitled Origine poétique des mines d'or et d'argent, neither of which attracted much notice. He next became a defender of the monarchy; and for publishing an anti-revolutionary work, entitled Déclaration des droits de l'homme, he was obliged for a time to conceal himself. In September, 1792, he established La Quotidienne, a daily journal in the royalist interest, the character of the articles of which caused him to be condemned to death, but the efforts of his friend Giguet preserved him from the guillotine. Adhering steadily to his opinions under the directory, he was banished after the 18th Fructidor (Sept. 4, 1797), and took refuge among the Jura mountains, whence he returned to France in November, 1799. He opposed the consulate with no less acrimony than he had shown toward the convention and the directory; and for an anonymous pamphlet, Adieu à Bonaparte (Paris, 1800), he was confined for a short time in the Temple. In 1801 appeared his Histoire des progrès et de la chute de l'empire de Myrore, sous le règne d'Hyder Ali et de Tippo Saib (2 vols. 8vo), followed by the Biographie moderne (4 vols. 8vo, Leipzig, 1802), printed in Paris by the brothers Michaud, a publishing firm established at the commencement of the century by himself, his brother Louis Gabriel, and Giguet. This publication was the germ of the later and more elaborate work, the Biographie universelle, published by the same house. In 1803 he published Le printemps d'un proscri, a poem written during his exile, which passed through many editions. His royalist views changed, and in 1810 he addressed a congratulatory poem to Napoleon on occasion of his marriage with Maria Louisa, under the title of Fragment d'un troisième livre de l'Enéide, and another in 1811 commemorating the birth of the king of Rome. His most important work, Histoire des croisades (1811 et seq.) went through five editions in his lifetime, the last being in 1840–41 (6 vols. 8vo), and has been translated into the principal languages of Europe. He published an abridgment of it (3 vols. 12mo, 1838), and in further illustration of the subject produced the Bibliothèque des croisades (4 vols.), and Correspondance d'Orient (7 vols.), the latter a record of his extensive travels in company with his pupil, Poujonlat, through those portions of the East traversed by the crusaders. After the overthrow of the empire Michaud reestablished the Quotidienne, but during the hundred days it became a mere vehicle of news. He published an account of the hundred days, of little historical value, which passed through 27 editions, and continued until the close of his life, in spite of feeble health, to devote himself to historical researches. Among his later publications were an edition of Hénault's Abrégé chronologique de l'histoire de France, with a continuation to July, 1830, and a Collection de mémoires pour servir à l'histoire de France, which was commenced in 1836, in conjunction with Poujonlat, and published in 34 vols. 8vo. His name has been most popularly associated with the Biographie universelle, published between 1811 and 1838, which, with its supplements, contains 28 volumes. He was a member of the French academy and of the academy of belles-lettres, and held other positions of honor and emolument. His brother Louis Gabriel, known as Michaud the younger (born in Bourg in 1773), had a large share in editing and writing the Biographie universelle, and commenced a new edition (vol. 1., 1854), which was completed after his death (March 12, 1858) in 45 volumes. He also wrote several historical and biographical works.

MICHAUX. 1. André, a French botanist, born in Versailles, March 7, 1748, died in Mada- gascar, Nov. 13, 1802. He studied under Bernard de Jussieu, and was afterward a pupil at the jardin des plantes, and an associate of Lamarck and Thouin in their botanizing excursions. After travelling in the Pyrenees and Spain he accompanied the French consul to Persia, and remained in the East for two years making botanical collections and observations. In the "garden of Semiramis" near Bagdad
he discovered a Persepolitan monument, which he sent to the cabinet of antiquities in the royal library at Paris. Commissioned by the French government in 1785 to make a journey through North America, he traversed a great part of the continent from Florida to Hudson bay, established botanical gardens near Charleston and New York, and sent home an immense quantity of plants and seeds. The New York garden was really in Bergen co., N. J. The government allowance for the expense of this undertaking having ceased at the revolution, he made use of his private purse until it was exhausted. On his voyage home he was shipwrecked and lost all that he possessed except four cases of specimens. He reached home in 1796, and found that the plantations to which he had contributed 60,000 young trees had been destroyed during the revolution. In 1800 he joined the expedition to Australia under Capt. Baudin, but left it at the Isle of France, and went to Madagascar, where he was attacked by fever and died. He left an Histoire des chênes de l'Amérique Septentrionale (fol., Paris, 1801), and Flora boreali-Americana (2 vols. 8vo, 1803). II. François André, a French botanist, son of the preceding, born in Versailles in 1770, died at Vauvéal, near Pontoise, Oct. 23, 1855. He was employed by the French government on a scientific mission to North America, to decide what species of the forest trees of that country might profitably be introduced into Europe, and made three voyages to the United States, whence he sent to France large quantities of valuable seeds. His principal work is Histoire des arbres forestiers de l'Amérique Septentrionale (4 vols. 8vo, Paris, 1810-'13), of which an English translation by the author was published in Paris and Philadelphia (4 vols. 8vo, 1817-'19), and another edition, translated by Hillhouse (Philadelphia, 1830). Three supplementary volumes were added by Thomas Nuttall in 1842-'9, which contained the trees not included in Michaux's work, and the whole is now published in five volumes, two by Michaux and three by Nuttall. He also published Mémoire sur la naturalisation des arbres forestiers de l'Amérique (Paris, 1805), and Voyage à l'ouest des monts Alleghanyens (1804; English translation, London, 1805).

MICHEL, Francisque Xavier, a French archeologist, born in Lyons, Feb. 18, 1809. He began his literary career in Paris as a writer for the journals, and in 1832 published two historical novels, Job and Audéfroi le bâtard. His chief attention, however, was given to philosophical researches, and between 1830 and 1833 he edited several publications written in medieval French, including La chronique de Du Gesclin, Les chansons de Courcy, Le lai d'Havelok le Danois, &c. In 1835 he was commissioned by Guizot, then minister, to make researches into early French history and literature among the libraries of England, and in 1839 he was appointed professor of foreign literature in the faculty of Bordeaux. Between 1834 and 1842 he published in London or Paris more than 30 works in French, Saxon, or English, written between the 11th and 14th centuries, many of which were then printed for the first time. Among the most important are: the Roman d'Eustache le Moine (1834); Tristan, a collection of poems of the 12th and 13th centuries in French, Anglo-Norman, and Greek (2 vols. 12mo, London, 1835); Chroniques Anglo-Normandes (3 vols. 8vo, Rouen, 1836-'40), illustrating the history of England and Normandy during the 11th and 12th centuries; La chanson de Roland (1837); Chroniques des ducs de Normandie (4 parts, 1837-'40), by the troubadour Benoît; La chanson des Saxons, by Jean Bodel (2 vols. 8vo, 1839-'40), a narrative of the life of Wittekind; "Chronicle of the War between the English and the Scots in 1173 and 1174" (1840); Histoire des ducs de Normandie et des rois d'Angleterre (1840); and Le roman du Saint-Grégoir, in verse (1841). He has also produced several original works of considerable erudition, including his Histoire des races maudites de la France et de l'Espagne (2 vols. 8vo, 1847); Le livre d'or des métiers (3 vols. 8vo, 1851-'4); Histoire des tissus de soie au moyen âge (2 vols. 4to, 1852-'5); Le pays Basque (1857); Les Ecossais en France et les Français en Écosse (1862); and Histoire du commerce et de la navigation à Bordeaux, principalement sous l'administration anglaise (1867). He has translated several English works.

MICHEL ANGELO. See Buonarroti.

MICHELET, Jules, a French historian, born in Paris, Aug. 21, 1798, died at Hyères, Feb. 9, 1874. He studied in the collège Charlemagne, and after travelling in Germany was called in 1821 to the chair of history in the collège Rollin, where he was also professor of the ancient languages and of philosophy till 1828, publishing in that period his Tableau chronologique de l'histoire moderne (1825), and Tableaux encyclopédiques de l'histoire moderne (1826). In 1828 he was made maître des conférences in the normal school, and in 1830 chief of the historical section of the archives of France. In that year Guizot, who was diverted from literature to politics, chose him to continue his lectures in the faculty of letters. His reputation was extended by a series of historical works, and in 1838 he was appointed to the chair of history in the collège de France, and elected a member of the institute. Among his publications are: Précis de l'histoire moderne (1823); Introduction à l'histoire universelle (1831); a translation of Vico's Scienza nuova, under the title of Principes de la philosophie de l'histoire (1831); Histoire romaine (1831); Mémoires de Luther (1833); and Précis de l'histoire de France jusqu'à la révolution française (1833). In 1833 appeared the first portion of his most important work, the Histoire de France (16 vols. 8vo, completed in 1867). His academical lectures were distinguished for
appeals in favor of democratic ideas and for assaults upon the Jesuits. He embodied these tendencies in three books: Des Jésuites (1843), in collaboration with his Du prêtre, de la femme et de la famille (1844); and Du peuple (1846). The government of Louis Philippe suspended his course. He was restored to his chair after the revolution of 1848, again declined public office as he had done in 1830, and gave to his lectures the design and character of democratic propa- gandism, till his course was closed by the government of Louis Napoleon in March, 1851. He lost his place in the archives after the coup d'état of Dec. 2, 1851, by refusing to take the oath. He published the Procès des templiers (2 vols., 1861-73), a collection of unprinted documents, and Origines du droit français cherchées dans les symbolos et formules du droit universel (1837), founded upon Grimm's work on German antiques. After his retirement he published a series of volumes entitled L'Oiseau (1856), L'Insecte (1857), L'Amour (1858), et la femme (1859), remarkable for their poetical and suggestive speculations. The last two were translated into English by J. W. Palmer, M. D. (New York, 1859 and 1860). The Histoire de la résolution française (6 vols., 1847-59), and Les femmes de la révolution (1854), form dis- tinct works. His later works are: La sorcière (1862); La Pologne martyre (1863); La Bible de l'humanité (1864); La Montagne (1866); Nos fils, advocating compulsory education (1869); and Histoire du XIXe siècle (1872). His more important publications have all appeared in English.—His second wife, Atha- naise Michelet, who survives him, had been a teacher in St. Petersberg. She opened a correspondence with him arising from her ardent admiration of his ideas, and they became en- gaged before they had seen each other. She assisted him in his labors, and, as preparing a new work, La nature, at the time of his death.

MICHIGAN, one of the western states of the American Union, and the 18th admitted under the federal constitution, situated between lat. 41° 45' and 44° 20' N., and lon. 82° 25' and 90° 34' W. It is bounded N. by Lake Superior; E. by St. Mary's strait or river, Lake Huron, St. Clair river, Lake St. Clair, the Detroit river, and Lake Erie; S. by Ohio and Indiana; and W. and S. W. by Lake Michigan and the Me- nomee and Montreal rivers, with the chain of lakes lying between their head waters. The bounding waters (except Lake Erie) on the north and east separate it from the province of Ontario, Canada; those on the west and southwest from Illinois and Wisconsin. The land area of the state is 56,451 sq. m. It is divided into 77 counties, viz.: Alcona, Allegan, Alpena, Antrim, Barry, Bay, Benzie, Berrien, Branch, Calhoun, Cass, Charlevoix, Cheboygan, Chippewa, Clare, Clinton, Crawford, Delta, Eaton, Emmet, Genesee, Gladwin, Grand Traverse, Gratiot, Hillsdale, Houghton,
MICHIGAN

Huron, Ingham, Ionia, Iosco, Isabella, Jackson, Kalamazoo, Kalkaska, Kent, Keweenaw, Lake, Lapeer, Leelanau, Lenawee, Livingston, Mackinaw, Macomb, Manistee, Manitou, Marquette, Mason, Mecosta, Menominee, Midland, Missaukee, Monroe, Montcalm, Montmorency, Muskegon, Newaygo, Oakland, Oceana, Ogemaw, Ontonagon, Osceola, Oscoda, Ocego, Ottawa, Presque Isle, Roscommon, Saginaw, Sanilac, Schoolcraft, Shiawassee, St. Clair, St. Joseph, Tuscola, Van Buren, Washtenaw, Wayne, and Wexford. There are 38 cities, as follows: Detroit, the commercial metropolis of the state, having a population in 1874 of 101,255; Grand Rapids, 25,923; East Saginaw, 17,084; Jackson, 15,809; Bay City, 13,990; Saginaw City, 10,064; Adrian, 8,403; Muskegon, 8,505; Port Huron, 8,240; Flint, 8,197; Lansing (the capital), 7,445; Ann Arbor, 6,231; Monroe, Battle Creek, Marquette, and Ypsilanti, having each more than 5,000 inhabitants; Manistee, Ishpeming, Marshall, Niles, Grand Haven, and Wexford. There are 65,720 persons born in the state living in other states and territories. Of the foreign population, 89,590 were born in British America, 64,145 in Germany, 42,013 in Ireland, 35,051 in England, 12,559 in Holland, 8,552 in Scotland, 8,121 in France, 2,406 in Sweden, 2,116 in Switzerland, 1,516 in Norway, 1,554 in Denmark, and 1,179 in Bohemia. There were in the state 274,459 male citizens of the United States 21 years old and upward. The number of families was 241,006, with an average of 4:91 persons to each; of dwellings, 237,036, with an average of 5 persons to each. There were 33,313 persons 10 years old and over who could not read, and 53,127 who could not write, of whom 22,547 were natives and 30,580 foreigners, 6,649 whites, 2,655 colored, and 1,823 Indians. Of the white and colored, 24,706 were males and 25,598 females; 8,921 were between 10 and 15 years of age, 5,428 between 15 and 21, and 37,485 (19,553 males and 18,932 females) 21 and over. The number of blind persons was 418; of deaf and dumb, 455; of insane, 814; of idiotic, 616. The number of paupers supported during the year ending June 1, 1870, was 8,151, at a cost of $369,682; number receiving support on that date, 2,042, of whom 1,189 were foreigners. The number of persons convicted of crimes during the year was 333; number in prison June 1, 1,085, of whom 416 were foreigners. Of the 404,164 persons (346,717 males and 57,447 females) 10 years old and upward returned as engaged in all occupations, there were employed in agriculture 187,211, including 121,558 farmers and planters and 64,885 agricultural laborers; in professional and personal services, 104,758, including 1,480 clergymen, 49,005 domestic servants, 36,084 laborers, 1,167 lawyers, 1,722 government employees and officials, 2,084 physicians and surgeons, and 5,059 teachers; in trade and transportation, 29,568; and in manufactures and mining, 92,657, including 4,720 blacksmiths, 5,556 brick and stone masons, &c., 1,799 car, carriage, and wagon makers, 14,693 carpenters and joiners, 2,045 cotton and woolen mill operatives, 1,075

Coldwater, with more than 4,000 each; Alpena, Negaunee, Hillsdale, Pontiac, Wyandotte, Ionia, Greenville, and Big Rapids, with more than 3,000 each; Lapeer, Charlotte, Holland, Owosso, Ludington, Hastings, and St. Clair, with more than 2,000 each; and Corunna, with a population of 1,345. The principal villages are Kalamazoo (pop. in 1870, 9,181), Allegan, Escanaba, Benton, Houghton, Hudson, Sault Ste. Marie, and Tomahawk. The population of Michigan at the several federal decennial enumerations since its organization as a territory has been as follows:

* Unorganized.
fishermen, 1,314 iron and steel workers, 2,341 lumbermen, raftsmen, and wood choppers, 1,150 machinists, 1,585 millers, 3,426 miners, 2,727 painters and varnishers, and 10,556 saw-mill operatives. The tribal Indians of Michigan in 1874 numbered 8,923, viz.: Ottawas and Chippewas, 6,170; Chippewas of Saginaw, Swan creek, and Black river, 1,575; Chippewas of Lake Superior, 1,118; and Pottawatomies of Huron, 60. The Ottawas and Chippewas reside in the N. part of the southern peninsula and on the islands of Lake Michigan; the Chippewas of Saginaw, &c., in Isabella co.; the Pottawatomies in Calhoun co.; the Chippewas of Lake Superior on L'Anse bay in Houghton co. The last named tribe depend for subsistence chiefly upon hunting and fishing; the others are largely engaged in agriculture. They are well advanced in civilization, mostly hold land in severalty, and are entitled to the privileges of citizenship. The agent of the Michigan Indians is nominated by the Methodists. There are several schools among them under the auspices of the Roman Catholics and Methodists.—Michigan consists of two irregular peninsulas, which are separated from each other by the strait of Mackinaw (4 m. wide) connecting the N. ends of Lakes Michigan and Huron. The upper or northern peninsula is bounded N. by Lake Superior, E. by St. Mary's strait, S. by Lake Huron, and W. by the strait of Mackinaw, and Lake Michigan, and S. W. by Wisconsin. It is 318 m. in greatest length from E. to W., and from 30 to 164 m. wide, embracing about two fifths of the area of the state. It comprises the counties of Chippewa, Delta, Houghton, Keweenaw, Mackinaw, Marquette, Menominee, Ontonagon, and Schoolcraft, and contains but a small portion of the peninsula (61,814 in 1874). From its W. extremity the Lake Superior shore trends N. E. for a distance of about 160 m. to the end of Keweenaw peninsula, a long peninsula running out into the lake. On the E. side of this peninsula is Keweenaw bay. Thence to Whitefish point the coast line presents a regular undulation with scarcely any good harbors. At Whitefish point it bends sharply S. and afterward E., enclosing with the Canada shore the deep basin known as Teguamenon bay, from the head of which flows St. Mary's strait. The Lake Huron shore, extending from the mouth of the St. Mary's westward to the strait of Mackinaw, is much broken and lined with islets; it is separated from Lake Michigan by the peninsula called Pointe St. Ignace. The shore of Lake Michigan is irregular, but offers no large inlets until Green bay is reached, which opens from the N. W. corner of the lake. More than half of the N. and W. shore of this bay belongs to Michigan, and just within its mouth are two inlets extending northward, called the Big and Little bays de Noquet. The general aspect of the northern peninsula is rugged and picturesque. The portion E. of the meridian of Marquette is an undulating plateau, sinking gradually toward the south and more rapidly toward the north, the watershed being much nearer Lake Superior than Lakes Huron and Michigan. The highest points do not rise more than 400 ft. above Lake Superior. Numerous lakes and marshes are scattered over this plateau. The surface is covered with forests, except where fires have destroyed the timber and transformed the region into a desert. Soft woods, including pine, are the prevailing growth, but fine groves of sugar maple and beech also occur. W. of the plateau the country is irregularly mountainous, interspersed with swamps and lakes. A few of the peaks attain a height of 1,400 ft. above Lake Superior. The N. W. extremity of the peninsula is occupied by the Mineral or Copper range, which properly consists of three ranges: the main or central range, extending from Keweenaw point far into Wisconsin, flanked on the north by the Porcupine mountain range, and on the south by the South Copper range. The general trend of these ranges is N. 60° E. and S. 60° W. They do not attain so great a height as some of the peaks further E. The timber here, which is abundant and of excellent quality, is generally sugar maple; but little pine or other soft wood occurs. Immediately S. of the South Copper range is the Iron range. The northern peninsula contains most of the mineral wealth of the state, but this area is generally sterile. The lower or southern peninsula, which is 277 m. in length from N. to S., and 259 m. in greatest width, is in nearly every respect a contrast to the northern. It lies between Lakes Huron and Michigan, and is bounded S. E. by the St. Clair river, Lake St. Clair, Detroit river, and Lake Erie. The Lake Huron shore is broken by Thunder bay toward the north and Saginaw bay near its centre. There are also several inlets on Lake Michigan, the chief of which are Great and Little Traverse bays. The surface is generally level, although in the eastern part it is irregular. The eastern part of the peninsula is an undulating plateau, with conical hills from 30 to 200 ft. high. A low watershed, culminating at an elevation of 600 or 700 ft., passes through the country from S. to N., much nearer the E. than the W. shore, with a very gradual and almost unbroken slope toward Lake Michigan, except near Au Sable river, where it partakes of a rugged character. The shores on both sides are in many places steep and elevated, and on Lake Michigan especially there are numerous bluffs and sand hills from 100 to 300 ft. high. The soil of the southern peninsula, except in the N. part, is luxuriantly fertile. The principal islands belonging to the state are Isle Royale and Grand island in Lake Superior; Sugar and Nebish islands in St. Mary's strait, and Drummond's island at its mouth; Marquette, Mackinaw, and Bois Blanc islands in the N. part of Lake Huron, near the mouth of the strait of Mackinaw; and the Beaver, Fox, and Manitous in the N. part of Lake Michigan.

—The principal rivers are the Ontonagon and
Tequamenon, flowing into Lake Superior; the Cheboygan, Thunder Bay, Au Sable, and Saginaw, into Lake Huron; the Huron and Raisin, into Lake Erie; and the St. Joseph, Kalamazoo, Grand, Muskegon, Manistee, Grand Traverse, Manistique, and Escanaba, into Lake Michigan. Most of these are small, but the streams are so numerous that all parts of the state are abundantly watered. The Grand, Saginaw, St. Joseph, and some others are navigable for short distances. Many small ponds are also scattered over the surface.—

The lower peninsula is composed wholly of groups of the Devonian and lower carboniferous series of rocks, except the central portion of the country, from which the streams flow on one side into Lake Huron, and on the other into Lake Michigan, which is occupied by the coal measures and permoo-carboniferous series. Though this is the most elevated portion of the peninsula, the surface is little more than moderately rolling, the strata are horizontal, and the bituminous coal beds lie mostly too low to be worked without raising the water by pumping. The coal field, which embraces about 12,000 sq. m., is open to Lake Huron by Saginaw bay, the shores of which are mostly in this formation. It extends as far S. as Jackson, on the line of the Michigan Central railroad, where a bed 4 ft. thick is opened and worked 30 ft. below the surface. From the difficulty of obtaining the coal in large quantities, but little of it is shipped, and even the supplies for the Lake Superior iron works are carried chiefly from eastern Ohio. Around the coal field the underlying carboniferous limestone crops out in a narrow belt, and contains in some localities gypseous shales and some plaster of Paris. To this succeeds the wider outcrop of the slates and sandstones of the Portage and Chemung groups, which stretch along the shores of both Lake Michigan and Lake Huron. The limestone of this portion of the Helterberg and Niagara groups surround these, sweeping around into northern Ohio and Indiana and eastern Wisconsin, and forming the island of Mackinaw and the point of the peninsula S. of this island. The mineral productions found in these formations are of no great importance. The limestones give fertility to the soil, and are abundantly supplied for all the purposes they can serve. From the shores of Lake Huron, near Thunder bay, an excellent stone is quarried for grindstones; and near Saginaw bay and in the valley of Saginaw river salt water is obtained by boring. The statistics of the production of salt, which is extensive and still increasing, are given below. The northern peninsula exhibits four geological formations: the lower Silurian; the copper-bearing rocks; the iron-bearing rocks, corresponding, it is assumed, with the Huronian system of Canada; and the granitic rocks, believed to be the equivalents of the Laurentian of Canada. The Silurian underlies the E. plateau, and flanks the Copper range on the south, forming also the valleys between the different members of that range. It is made up of various sandstones and limestones. The copper-bearing rocks are confined to the Mineral or Copper range, but occur outside of the peninsula on Isle Royale. This is the most productive copper district in the world, except Chile. Silver is frequently found in connection with the copper. The N. and W. portions of the central region of the peninsula, bordering on Lake Superior and the copper-bearing series, are occupied by the Huronian formation, which consists of a series of extensively folded beds of diorite, quartzite, chloritie schists, clay and mica slates, and graphitic shales, among which are intercalated the extensive beds of magnetic, specular, and other iron ores, for which this region is famous. The rest of the peninsula is occupied by the Laurentian series. The copper mines are in Ontonagon, Houghton (which contains the richest mines), and Keweenaw cos. The iron mines are in Marquette co. According to the census of 1870, there were 27 copper mines, with 86 steam engines of 5,943 horse power; hands employed, 4,188; capital invested, $5,866,374; wages paid, $2,346,535; value of product, $4,312,167 (total product of the United States, $5,501,312). The number of iron mines was 11, with 20 steam engines of 925 horse power; hands employed, 2,005; capital invested, $8,810,000; wages paid, $1,270,708; tons of ore obtained, 494,393; value, $2,677,965. The yield of iron ore was greater than that of any other state except Pennsylvania. The yield of copper ore in 1873 was 18,636 tons (2,000 lbs. each), and the aggregate product of the mines from their opening in 1845 to the close of that year was 194,353 tons. The iron product of the state in 1873 was 1,250,000 tons (2,240 lbs.) of ore mined and 75,000 tons of pig iron manufactured. The total yield from the opening of the mines in 1856 to the close of 1873 was 27,784,125 sq. m., and 428,580 tons of pig iron. (See Copper Mines, and Iron Ore.)—Michigan abounds with natural objects and antiquities interesting to the traveller. Among the former the most noteworthy are the "Pictured Rocks," on the shores of Lake Superior, about 30 m. W. of Sault Ste. Marie. These are sandstone bluffs of various colors, worn by the action of the waters into grotesque forms resembling castles, temples, arches, colonnades, &c., which from a steamer on the lake gave the appearance of a gorge to the picture. These rocks extend along the shore for about 12 m., and rise from 200 to 300 ft. above the water. Sometimes cascades shoot over the precipice so that a vessel may sail between the descending waters and the natural wall of rock. In the northern peninsula and on Isle Royale there are the remains of very ancient mines and mining tools, and it is evident that a race well advanced in civilization occupied the country at some very distant period in the past, of which the Indians found in possession by the early explorers from Canada could
give no account. Foster and Whitney ("Executive Document No. 69," 31st congress, 1st session) give an interesting chapter on this subject.—The climate of Michigan is one of extremes, but much tempered by the proximity of the lakes. That of the southern peninsula is comparatively mild, while that of the northern, especially in the winter season, is cold and rigorous. The mean annual temperature at Detroit (lat. 42° 29', elevation 580 ft.) from 1836 to 1854 was 47° 25'; and at Fort Brady, near Sault Ste. Marie (lat. 46° 30', elevation 600 ft.) from 1823 to 1854, 40° 27'. These results illustrate the isothermal conditions of the two peninsulas, the difference in annual heat being nearly 7° F. The mean distribution of the heat to the seasons in the same year was as follows:

<table>
<thead>
<tr>
<th>PLACES</th>
<th>Spring</th>
<th>Summer</th>
<th>Autumn</th>
<th>Winter</th>
</tr>
</thead>
<tbody>
<tr>
<td>Detroit</td>
<td>45° 59'</td>
<td>67° 60'</td>

<tr>
<td>Fort Brady</td>
<td>37° 60'</td>
<td>62° 01'</td>
<td>43° 44'</td>
<td>18° 31'</td>
</tr>
</tbody>
</table>

At Detroit the greatest difference in the monthly mean in any one year was 49° 97' (21° 95' to 71° 92'), and at Fort Brady 57° 81' (13° 19' to 71°). The average annual rainfall at the two places was 30-07 and 31-35 inches respectively, and in the seasons as follows:

<table>

</tbody>
</table>

The mean annual temperature at Grand Haven (lat. 43° 5' e, elevation 616 ft.) for the year ending Sept. 30, 1873, was 44° 6'; mean temperature of the coldest month (January), 19° 2'; of the warmest (June and August), 69° 1'. The annual mean at Escanaba (lat. 45° 44', elevation 601 ft.) was 40° 01'; coldest month (December), 11° 9'; warmest (June), 69° 8'; total annual rainfall 25-77 inches. At Marquette (lat. 46° 39', elevation 666 ft.) the annual mean was 38° 3'; coldest month (December), 12°; warmest (August), 63°; total annual rainfall, 23-46 inches. The whole number of deaths in 1870 was 11,181, of which 4,822 were from general diseases, 1,349 from diseases of the nervous, 407 of the circulatory, 1,025 of the respiratory, and 1,800 of the digestive system. Among special diseases, there were 707 deaths from scarlet fever, 686 from enteric fever, 153 from intermittent fever, 97 from remittent fever, 1,844 from consumption, and 702 from pneumonia.—The northern peninsula with some exceptions is rugged and has a poor soil. It is, however, well timbered with white pine, spruce, hemlock, birch, oak, aspen, maple, ash, and elm. Much of the southern is occupied by oak openings and prairie, with a large portion of forest, in which walnut, sugar maple, oak, hickory, ash, basswood, elm, Linden, locust, dogwood, beech, sycamore, cherry, pine, hemlock, spruce, tamarack, cypress, cedar, and chestnut are the prevailing growths. White pine forms the chief wealth of the N. half of this peninsula. The upper portion of the state is beyond the N. line of Indian corn, but here the harder grains mature. The southern produces Indian corn and the winter grains abundantly, and is the great agricultural district of the state. The soils in this portion are deep, chiefly a dark loam, often mixed with gravel and clay, and very fertile. Apples are grown here in great quantities. Peaches are successfully raised on the shores of Lake Michigan, while pears, plums, cherries, blackberries, raspberries, strawberries, and quinces flourish throughout the state. The vine is cultivated on the shores of Lakes Michigan and Erie, and in the principal river valleys. The lakes and streams afford productive fisheries, among which are those of the far-famed whitefish. According to the census of 1870, Michigan was 10th among the states in the value of agricultural productions, and 9th in the value of manufactures. The whole number of farms was 98,786, of which 6,897 contained less than 10 acres each, 13,170 from 10 to 20, 33,795 from 20 to 50, 27,687 from 50 to 100, 12,175 from 100 to 500, 57 from 500 to 1,000, and 5 more than 1,000 acres each. The number of acres of land in farms was 10,019,142, of which 5,096,939 were improved; cash value of farms, $398,240,378; of farming implements and machinery, $18,711,979; wages paid during the year, including the value of board, $8,421,161; estimated value of farm productions, including feedings and additions to stock, $81,508,623; value of orchard products, $3,447,985; of produce of market gardens, $352,658; of forest products, $2,559,682; of home manufactures, $338,008; of animals slaughtered or sold for slaughter, $11,711,624; of live stock, $49,809,869. The chief productions and live stock according to the census of 1870 and the state census of 1874 were:

The number of manufacturing establishments in 1850 was 2,083, producing goods to the value of $11,169,002. In 1860 there were 3,448 establishments; hands employed, 23,190: capital invested, $23,808,226; value of products, $32,658,536. The whole number of establishments in 1870 was 9,455, having 2,165 steam engines of 70,956 horse power, and 1,500 water wheels of 34,895 horse power; number of hands employed, 69,694, of whom 58,547 were males above 16, 2,941 females above 15, and 2,406 youth; capital invested, $71,712,283; wages paid, $91,205,355; value of materials used, $68,142,515; of products, $118,394,676. The statistics of the principal branches (1870) are shown in the following table:

The total value of saw-mill products was greater than that of any other state. In the quantity of laths and lumber produced Michigan stood first; in the quantity of shingles, next to Wisconsin; and in the value of staves, &c., next to Indiana and New York. The number of steam engines employed in the saw mills was 1,137, of 41,216 horse power; water wheels, 547, of 12,448 horse power; number of saws, 7,052; amount of wages paid during the year, $6,400,283; value of materials used, $14,347,661. The products were 3,251,813,000 feet of lumber, 658,741,000 shingles, and staves, shooks, headings, &c., to the value of $1,322,692. The whole number of bushels of grain ground was 16,801,910, and the products of the flouring mills intended for market (excluding flour, meal, &c., from grain ground for individual owners) were 10,936 cwt. of buckwheat flour, 3,759 barrels of rye flour, 963,101 of wheat flour, 3,875 bushels of oats, 10,850 of corn meal, and 1,508,180 cwt. of feed. There were 119,415 tons of iron ore smelted, producing 79,279 tons of pig iron. The quantity of salt manufactured was 3,981,316 bushels, more than was produced by any other state except New York and West Virginia. The quantity of lumber manufactured in 1873 amounted to 2,856,351,027 feet, viz.: E. Michigan, 1,351,870,286 feet; W. Michigan, 1,208,559,798; upper peninsula, 133,913,002; railroad and interior mills, 175,000,000. If the lumber cut into shingles were added, the aggregate would nearly reach 3,000,000,000 feet. The forest of the state are rapidly disappearing, but it is estimated that 33,000,000,000 feet of pine timber is still standing in the lower peninsula. The product of the salt wells for 1874 was 1,026,979 barrels. The total yield from the discovery of the wells in 1860 to the close of 1874 has been 7,789,419 barrels. The lake fisheries are of considerable importance. The value of the catch according to the census of 1870 was $587,257; the chief items were 2,165 barrels of herrings, 2,797 of pickerel, 47,436 of whitefish, and 14,268 of other fish.—Michigan is divided into four customs districts, viz.: Detroit, Huron (port of entry, Port Huron), Michigan (port of entry, Grand Haven), and Superior (port of entry, Marquette). The foreign commerce (except under the act of July 14, 1870, which permits the shipment of goods without appraisement to interior ports from the ports of first arrival) is carried on wholly with Canada, though an occasional vessel has been despatched from Detroit directly to Europe. The following table exhibits the statistics for the year ending June 30, 1874:

The exports consist chiefly of grain, flour, hogs, lumber, beef and pork and their products, tobacco, cotton, and railroad cars. Of the exports through the district of Huron a large proportion is transported by land carriage. The number of entrances in 1873 was 4,355, with an aggregate tonnage of 1,357,462. The number of clearances in the same year was 4,275, tonnage 1,340,532. The vessels engaged in the coastwise trade for the year ending June 30, 1874, and the number built during the previous year, were as follows:

The vessels belonging or registered in the state consisted of 368 sailing vessels of 52,907 tons, 355 steamers of 68,229 tons, and 213 unrigged vessels of 37,387 tons; those built included 42 sailing vessels of 15,838 tons, 84 steamers of 8,884 tons, and 17 unrigged vessels of 4,585 tons. The number of entrances in 1873 was 18,124, of 4,205,694 tons (4,783 of 2,056,040 tons steamers); clearances, 18,436 of 4,800,173 tons (4,855 of 2,070,157 tons steamers). The number of miles of railroad in the state in 1844 was 206; in 1854, 444; in 1864, 898. The lines in operation in 1874, with their termini and their mileage within the state, were:

**RAILROADS**

- **Chicago and Michigan Lake Shore**
  - Branches
    - Chicago and Canada Southern
    - Chicago and Northwestern (Peninsula division)
  - Detroit, Hallowell, and Indiana
  - Detroit, Lansing, and Lake Michigan

- **Detroit, Monroe, and Toledo**
  - Flint and Pere Marquette

- **Fort Wayne, Jackson, and Saginaw**
  - Grand Rapids and Indiana
  - Grand Rapids, Newaygo, and Lake Shore
  - Grand River Valley
  - Hecla and Torch Lake
  - Jackson, Lansing, and Saginaw

* Operated by the Lake Shore and Michigan Central railroad.
† Operated by the Michigan Central railroad.
‡ Consolidated in 1873 under the title of the Chicago and Lake Huron railroad.
The only canals used for transportation are the St. Mary's ship canal and the Portage and Lake Superior ship canal. The former, about a mile long, around the falls of the St. Mary's at Sault Ste. Marie, was opened in 1856, and has been of great importance in facilitating commerce between Lakes Huron and Superior. The latter is about two miles long, and connects Portage lake with Lake Superior on the W. side of Keweenaw point. By opening a navigable channel through the base of the peninsula, it enables vessels to avoid the circuit around the point. It was completed in 1873.

—in 1873 there were 77 national banks in the state, with a capital of $8,502,200, and an outstanding circulation of $7,159,217; 13 state banks, with a capital of $1,184,897 $0; and 10 savings banks, with a capital of $631,300, and deposits amounting to $4,000,000. There were 31 mutual fire insurance companies and 3 stock (1 fire and marine) of the state in operation, besides 88 companies of other states and 11 foreign companies authorized to do business in Michigan; also 37 life insurance companies, of which one, with a capital of $100,000, was a Michigan company. —The executive power of the state is vested in a governor (salary $1,000), lieutenant governor, secretary of state ($800), superintendent of public instruction ($1,000), state treasurer ($1,000), auditor general ($1,000), commissioner of the state land office ($800), and attorney general ($800), elected by the people for two years. The lieutenant governor is ex officio president of the senate, and upon the death, resignation, or disability of the governor exercises the functions of that office. The secretary, treasurer, and commissioner of the land office constitute a board of state auditors, to examine and adjust claims against the state, and also a board of state canvassers, to determine the result of elections for state officers. The secretary, treasurer, and auditor are a board of internal improvements, and the lieutenant governor, auditor, secretary, treasurer, and commissioner of the land office form the state board of equalization. A commissioner of insurance, railroad commissioner, commissioner of immigration, and salt inspector are appointed by the governor with the consent of the senate, for life and the others for two years. The state board of health consists of seven members, including the secretary, and the state board of agriculture of the governor and president of the agricultural college ex officio, with six other members. The legislative power is vested in a senate and house of representatives, elected every second year. There are 32 senate districts, each of which elects one senator. The representatives, not fewer than 64 nor more than 100 in number (at present 100), are apportioned among the counties and representative districts according to population. After each United States census, and also after each decennial state census (beginning in 1854), a reapportionment is made. Members of the legislature and the lieutenant governor receive $3 a day while in actual attendance, and 10 cents a mile in going to and from the seat of government. The regular sessions are held biennially in odd years. No one holding a United States, state, or county office, with minor exceptions, is eligible to a seat in the legislature. Appropriations for any religious sect or society, or theological or religious seminary, are prohibited; and no act can be passed authorizing the granting of licenses for the sale of ardent spirits or other intoxicating liquors. The constitution forbids the granting of the credit of the state to or in aid of any person, association, or corporation, and declares that the state shall not subscribe to nor be interested in the stock of any company, association, or corporation, nor engage in any work of internal improvement. The governor's veto can be set aside by a two-thirds vote of both houses. The judicial power is vested in a supreme court, circuit courts, probate courts, and justices of the peace, with such municipal courts as may be established by the legislature in cities. The supreme court consists of a chief justice and three associate justices (salary $4,000), elected by the people for eight years (one retiring every two years), and has appellate jurisdiction. Four terms are held annually at Lansing. The state is divided into 20 judicial circuits, in each of which a circuit judge (salary $1,500) is elected for six years. Circuit courts are held in each organized county, and have general original jurisdiction, civil and criminal, and appellate jurisdiction of judgments of inferior courts. A probate judge is elected in each county for four years, who holds a probate court with the usual powers. Four justices of the peace are elected in each township for a term of four years, with jurisdiction in civil cases involving not more than $300, and such criminal jurisdiction as may be prescribed by law. The right of suffrage is conferred on all male citizens of the United States (including civilized Indians not members of any tribe) 21 years old and upward, who have resided in the state three months and in the township or ward where they offer to vote 10 days. General elections occur on the Tuesday after the first Monday of November in even years. Any inhabitant engaging in a duel is disqualified from voting and holding office. Amendments to the constitution must be proposed by two thirds of each house of the legislature, and ratified by the people. Once in 18 years, beginning with 1866, the question of calling a convention to revise the constitution is to be submitted to the people. Treason is punishable with death; murder in the first degree with solitary confinement in the state prison at hard labor for life; other crimes with fines and various terms of imprisonment. A married woman may carry on business in her own name; her property is not liable for the debts of her husband, and she may deal with it and sue and be sued...
respecting it as if unmarried. The principal grounds of divorce are adultery, impotence at the time of marriage, imprisonment for three years, desertion for two years, habitual drunkenness, and extreme cruelty. The rate of interest is 7 per cent., but as high as 10 per cent. may be stipulated for in writing. Michigan is entitled to two senators and nine representatives in congress, and therefore has eleven votes in the electoral college. — The valuation of property, according to the United States censuses, has been as follows:

The total taxation not national in 1870 was $5,412,957, of which $396,322 was state tax, $1,565,163 county, and $3,451,442 town, city, &c. The total debt amounted to $6,725,231, of which $2,385,028 was state, $1,275,479 county, and $8,664,724 town, city, &c. The receipts into the state treasury during the year ending Sept. 30, 1873, were $2,192,491 52; balance on hand at the beginning of the year, $777,234 08; disbursements, $2,314,494 11; balance in treasury at the close of the year, $854,713 44.

The items of receipt were as follows: from direct taxes, $992,230 50; specific taxes, $347,554 74, of which $211,239 56 were from rail-road companies, $118,131 84 from insurance companies, $18,778 37 from mining companies, $2,236 48 from telegraph companies, $2,016 54 from express companies, and $152 from river improvement companies; sale of lands, $250,700 42; interest on part paid lands, $73,902 45; St. Mary's canal, $29,571 86; 5 per cent. from United States on sale of public lands, $285,723 29; miscellaneous sources, $253,426 67; total cash receipts, $1,945,567 83; receipts in land warrants, $233,170 01; refundings and reimbursements, $13,693 68. The disbursements were as follows: for principal of state debt, $502,000; interest on state debt, $117,748 48; interest on trust funds, $196,318 62; interest on part paid lands, paid to educational institutions, $50,490 39; state institutions, from appropriations, $380,756 50 (University $30,000, normal school $15,984 07, agricultural college $25,000, state public school $30,513 49, reform school $18,500, state prison $27,500, insane asylum $127,400, deaf and dumb and blind asylum $10,063); new state offices and new capitol, $129,143 76; on account of canal, $14,207 80; miscellaneous, $672,412 87 (including for printing and binding $58,347 96, paper and stationery $44,423 56, salaries $148,557 89, pay and contingent expenses of legislature $73,176 48); total disbursements in cash, $2,068,078 42; disbursements in land warrants, $233,170 01; refundings and reimbursements, $13,693 68. The taxable value of property in 1871, when the last assessment was made, was $630,000,000. The taxation for state purposes for the year ending Sept. 30, 1874, was $982,290 50, or 15.59 cents on $100. The items are as follows: for agricultural college, $37,398; insane asylums, $189,000; general purposes, $300,000; institution for deaf and dumb and blind, $46,000; military fund, $33,382 50; new state capitol, $200,000; state prison building, $50,000; state public school, $43,000; state reform school, $33,950; university, $69,500. The total taxation, not including city taxes in the larger cities and special assessments (amounting probably to $1,000,000, for the year ending Sept. 30, 1873, was $11,660,055 84, viz.: state, $829,076 05; county, $2,660,318 35; township, $1,065,113 22; highway, $2,537,807 27; school, $1,098,698 39; drain, $241,864 60; miscellaneous, $328,092 96. The total bonded debt of the state Sept. 30, 1873, was $1,733,292 78, of which $1,699,000 was interest-bearing, viz.: due Jan. 1, 1878, $353,000; due July 1, 1878, $111,000; canal bonds (guaranteed by state) due July 1, 1879, $73,000; due Jan. 1, 1883, $699,000; due May 1, 1890, $463,000. The rate of interest on the last amount is 7 per cent.; on the rest, 6 per cent. The cash in the treasury applicable to the payment of this debt amounted to $412,000 30. The trust debt was owed to five primary school funds, $2,401,198 86; university fund, $381,234 03; agricultural college fund, $108,192 39; normal school fund, $50,138 22; railroad and other deposits, $4,227 46; total, $2,889,990 96. — The charitable, penit. pauper, and reformatory institutions are under the general supervision of a board of four commissioners (besides the governor ex officio), who are appointed by the governor with the consent of the senate for eight years, one retiring every two years. The state institutions under their charge are the state prison at Jackson, the reformatory school at Angola, the state public school at Coldwater, the asylum for the insane at Kalamazoo, and the institution for the education of the deaf and dumb and the blind at Flint. The state prison was established in 1838. The grounds embrace about 30 acres, of which 10 1/2 are enclosed within the prison walls. The number of cells is 648; they are built of stone, and each is 8 ft. 4 in. long, 3 ft. 4 in. wide, and 7 ft. high. The prisoners labor an average of about nine hours each week day in workshops in the enclosure; their services are let to contractors, and they are employed chiefly in the manufacture of furniture, wagons, agricultural implements, cigars, and boots and shoes. For the last few years the prison has been self-sustaining. The number of convicts in prison Sept. 30, 1872, was 589; received during the year, 287; discharged, died, &c., 221; remaining Sept. 30, 1873, 655. There is a library of about 2,000 volumes. The reform school for juvenile offenders was opened in 1856; it has a farm of 225 acres. The boys receive instruc-
tion in the elements of learning and are trained to habits of industry. Two family houses have recently been erected, affording accommodations for 75 boys of the smaller and better class, where they may be free from the example of the more vicious. The number of inmates Sept. 30, 1872, was 215; received during the year, 101; released, 97; remaining Sept. 30, 1873, 222. The state public school for neglected and dependent children was established by the act of April 17, 1871, and was opened May 22, 1874. The grounds embrace 27 acres, and the buildings comprise a large central structure for school and industrial purposes and several cottages in which the pupils may be separately classified, having accommodations for 165 inmates; the number in the institution on Aug. 15, 1874, was 195. The children are kept in school 41 hours a day, and those that are old enough work three hours a day. It is estimated that there are about 300 children in the state between the ages of 4 and 16 years who come within the design of this institution. The asylum for the insane was opened in 1859. The grounds embrace 196 acres, part of which is occupied as a farm and garden. With the new building to be completed in 1876 the institution will have accommodations for 500 patients in the female and 260 in the male department. The expenses are defrayed chiefly by receipts from inmates and from counties for the support of poor patients, with appropriations by the legislature to meet deficiencies. The number of patients Dec. 1, 1870, was 305 (156 males and 149 females); received during the succeeding two years, 155 (99 males and 56 females); discharged, 155 (recovered 56, improved 32, unimproved 40, died 27); remaining Sept. 30, 1872, 305 (157 males and 148 females). The number in the institution on Aug. 14, 1874, was 405, of whom 222 were males and 233 females. The legislature in 1874 appropriated $400,000 for the erection of another insane asylum, and Pontiac has been selected as the site. The institution for the education of the deaf and dumb and the blind was organized in 1854. Workshops have recently been connected with it, in which the pupils are taught mechanical occupations. The mental training is similar to that given in other institutions of the kind. The farm and garden comprise 54 acres. The number of pupils in attendance during the two years 1871 and 1872 was 219, of whom 171 (98 boys and 73 girls) were deaf mutes and 48 (25 boys and 23 girls) blind. The number remaining Sept. 30, 1872, was 164, of whom 187 were deaf mutes and 27 blind. The Detroit house of correction is a city institution, but it receives all females sentenced to the state prison and criminals convicted of misdemeanors from all parts of the state, for whose board and payment is made by the state or counties. The prisoners are principally employed in the manufacture of chairs and cigars, under the direction of the superintendent, and the earnings exceed the expenses. Provision is made for the education of the inmates, and in the house of shelter connected with the institution a limited number of the girls are surrounded with the influences of a home. The number of prisoners Jan. 1, 1873, was 449; received during the year, 3,409; discharged, 2,921; remaining Dec. 31, 1873, 381, of whom 416 were males and 115 females. Of those received during the year, 1,804 were from the city of Detroit, 591 from other parts of the state, and 10 from other states (United States prisoners). The commissioner also have the general oversight of the county jails and poorhouses. The number of jails is about 50. They vary from cheap log structures to expensive and imposing edifices, some costing less than $100 and others $50,000 or $50,000. The estimated value of jail property is $400,000. The average number of inmates is about 300; annual cost of maintaining jails, $50,000. There are 51 poorhouses, each having a farm connected with it; but few of the buildings have been constructed especially for the purpose. The whole number of paupers received in the county poorhouses and Washitawen and Wayne county asylums for the insane, during the year ending Sept. 30, 1873, was 3,798; average number maintained, 1,482; number under 18 years of age, 577; number of persons temporarily relieved outside the poorhouses, 13,765; whole amount expended from the poor fund, $403,096 18, of which $147,722 53 was for the maintenance of poorhouses, and $158,089 25 for temporary relief outside; estimated value of farms and appurtenances, $608,547; of paupers' labor, $7,628 50; of products of the farms, $60,519 15. The whole number of insane persons received was 412, average number maintained 254; whole number of idiots 196, average number 178; whole number of blind 47, average number 39; whole number of mutes 12, average number 11. Of those received during the year, 1,551 were native-born whites, 139 colored, 16 Indians, 36 of unknown birth, and the rest foreign.- Michigan has an excellent system of nearly 6,000 free public schools. Districts having fewer than 40 children between 5 and 20 years of age are required, under a heavy penalty, to have three months' free school annually; districts with over 80 children, five months; and districts with over 800, nine months. The actual average length is a little over seven months. The state superintendent of public instruction has the general oversight and supervision of these and all other educational institutions of the state, including in some respects all the local and denominational colleges. A county superintendent of common schools is elected in each county for two years, whose duty it is among other things to examine candidates for the position of teacher and grant certificates for his county. The state superintendent of public instruction may grant certificates effectual throughout the state.
A board of township school inspectors is elected annually, the township clerk being ex officio clerk of the board, with power to divide the township into districts. Each school district has a board elected by its voters, consisting of a moderator, a director, and an assessor, one being elected annually for three years. Any district having more than 100 children of school age may by a two-thirds vote decide to have a board of six trustees, two being elected annually for three years. These boards, when directed by a vote of the people, have power to establish graded schools and high schools. For graded schools two or more contiguous districts having together more than 200 scholars may unite. The income of the primary school fund is apportioned by the superintendent of public instruction to the townships and cities in proportion to the number of youth in each between the ages of 5 and 20 years. The act of April 15, 1871, requires all children between 8 and 14 years of age to be sent to the public schools at least 12 weeks in a year (six weeks at least of which shall be consecutive), unless taught at home or in a private school. According to the report of the superintendent of public instruction for 1873, the number of school districts was 5,521; children between 5 and 20 years of age, 821,322; between 8 and 14, 181,604; whole number attending school during the year, 324,615; number in attendance under 5 or over 20 years of age, 5,554; average attendance, 162,300; average length of schools, 7 months; number of school houses, 5,572 (80 stone, 641 brick, 4,246 frame, 605 log); seats, 399,067; value of school houses and lots, $8,105,391; number of teachers employed, 11,950 (3,010 males and 8,940 females); number of township libraries, 207, with 49,291 volumes; of district libraries, 1,089, with 115,381 volumes. Of the schools 311 were graded, with a total attendance of 118,616. The amount on hand at the beginning of the year was $590,589; 587,772.48, in township tax, $845,912.84; primary school fund, $194,479.58; tuition of non-resident pupils, $31,199.81; district taxes, $2,095,220.17; other sources, $412,253.87. The expenditures were $3,143,885.52, viz.: wages of male teachers, $681,563.24; of female teachers, $1,071,309.43; construction and repairs, $597,006.68; other purposes, $788,902.96; balance on hand at the close of the year, $594,467.18; total debt of school districts, $1,707,700.16. The state normal school at Ypsilanti was established by the act of March 28, 1849, and went into full operation in the spring of 1858. This is managed by a state board of education, consisting of the superintendent of public instruction, who is ex officio secretary, and three members elected by the people for six years, one retiring biennially. There are three courses of study: one of two years, designed to prepare students to teach in the common schools; another of three years, embracing higher English studies; and the third of four years, including ancient or modern languages. A model school is connected with the institution. Applicants for admission, if females, must be not less than 16, or if males not less than 18 years of age, and are required to sign an application of intention to devote themselves to the business of teaching in the schools of the state. Two students from each representative district are exempt from the payment of tuition; others are required to pay $10 a year. The diploma of the school entitles the possessor to teach in the public schools without examination. The number of instructors in 1873-4 was 14; of students in the normal department, 564; of pupils in the model school, 122; of volumes in the library, 2,000. According to the United States Census of 1870, the number of schools was 5,395, with 2,960 male and 5,560 female teachers, 129,949 male and 187,678 female pupils, and an income of $2,550,018 ($81,775 from endowment, $2,097,122 from taxation and public funds, and $371,121 from other sources, including tuition). Of the whole number of schools, 5,414 (3 normal, 37 high, 62 grammar, 570 graded common, and 4,742 ungraded common) were public, and 181 not public, having 582 teachers, 11,799 pupils, and an income of $385,529, of which $51,775 was from endowment, $711,500 from taxation and public funds, and $225,204 from other sources, including tuition. The school funds were divided as follows: classical, 13 (9 colleges and 3 academies); professional, 3 (1 law, 1 medical, 1 theological); technical, 18 (1 agricultural, 6 commercial, 1 for the blind and the deaf and dumb, 10 of music); day and boarding, 119; parochial and charity, 29. The statistics of the colleges of Michigan for the year 1873-4 are contained in the following table:

* 1872-3. † Date of reorganization under general law.
The state agricultural college was established by the act of Feb. 12, 1855, and was opened for the reception of students in May, 1857. Subsequently the land (240,000 acres) received by the state for the endowment of a college of agriculture and the mechanic arts, under the act of congress of July 2, 1862, was bestowed upon this institution: 64,598 acres have been sold, producing a fund of $207,500 74, the interest of which is applied to the support of the college. An annual appropriation is also made by the legislature. Tuition is free to students from the state; those from other states pay $20 a year. The institution has a farm of 676 acres (300 under cultivation), valuable collections of plants, animals, and minerals, a chemical laboratory and apparatus, philosophical and mathematical apparatus, and a museum of mechanical inventions. The branches of study comprise logic and philosophy, elementary, analytical, and agricultural chemistry, chemical physics, meteorology, practical agriculture, botany, horticulture, landscape gardening, physiology, zoology, entomology, geology, mathematics, physics, civil engineering, and English language and literature, with French in the senior year. The regular course is four years, upon the completion of which the degree of bachelor of science is conferred. Candidates for admission are required to be at least 15 years old, and to pass an examination in the common English branches. The students labor three hours a day on the farm or in the garden, for which they receive remuneration. Besides those mentioned in the table, the faculty of instruction in 1872-3 embraced seven others, including farmers, gardeners, steward, &c. The students were divided as follows: resident graduates, 3; seniors, 17; juniors, 22; sophomores, 24; freshmen, 52; in special courses, 14; in chemical manipulation, 8; ladies, 3. For an account of the state university, see Michigan, University of. The other institutions in the table, except the last, admit both sexes, and have a preparatory department, besides a collegiate department embracing usually a classical and a scientific course. Adrian and Olivet colleges have normal courses, and Adrian, Hillsdale, and Hope colleges theological departments. The Detroit medical college, founded in 1808, in 1873-4 had 17 professors and 72 students. The Detroit homeopathic college was organized in 1871, and admits both sexes. In 1874 it had 8 professors.—The census of 1870 returns 26,763 libraries, containing 2,174,744 volumes, of which 23,761, with 1,596,1.18 volumes, were private. Of those not private, there were 1 state, with 31,265 volumes; 423 town, city, &c., 124,207; 49 court and law, 10,569; 246 school, college, &c., 97,724; 1,731 Sabbath school and the mission church, 81,891; and 116 circulating libraries, 53,704. The number of newspapers and periodicals was 211, issuing 10,666,978 copies annually, and having a circulation of 253,774, viz.: 16 daily, circulation 27,485; 3 tri-weekly, 5,000; 174 weekly, 192,889; 2 semi-monthly, 1,300; 16 monthly, 27,100. They were classified as follows: advertising, 2; agricultural and horticultural, 1; benevolent and secret societies, 2; commercial and financial, 3; illustrated, literary, and miscellaneous, 17; political, 107; religious, 7; technical and professional. Five are printed in Dutch and 8 or 10 in German. The statistics of churches for 1870 are contained in the following table:

The name Michigan appears to be derived from the Chippewa words mitche, great, and saxgojewn, lake, and was formerly applied to both Huron and Michigan, but is now restricted to the latter lake. The discovery and early settlement of the state are due to the French missionaries and fur traders. The site of Detroit was visited as early as 1610, and in 1641 some French Jesuits reached the falls of the St. Mary. The first European settlement within the limits of the state was the mission at Sault Ste. Marie, which was founded by Father Marquette and others in 1668. Fort Michilimackinac (now Mackinaw) was established three years later. In 1701 an expedition under Antoine de la Mothe Cadillac founded Detroit. From this period until the erection of the country into a territory of the United States, Michigan made slow progress. It came under the dominion of Great Britain with other French possessions in 1763. On the expulsion of the French the conspiracy headed by the Indian chief Pontiac, and designed for the extermination of the whites, broke out and involved the settlements in bloodshed. The garrison of Michilimackinac was butchered, and Detroit underwent a long siege. On the treaty of peace which closed the revolutionary war, Michigan was not at once surrendered,
and the Americans did not take possession of Detroit till 1796. At first it was included in the government of the territory northwest of the Ohio, and hence has always been amenable to the ordinance of 1787. Subsequently it formed part of the territory of Indiana. In 1805 the territory of Michigan was constituted, Gen. William Hull being its first governor. During the war of 1812-15 it was exposed to great suffering. Detroit was taken by the British in August, 1812, under circumstances which led to Gen. Hull, the American commander, being sentenced to death by a court martial; the sentence was remitted, and facts afterward divulged materially relieved him from blame. Michilimackinac was also captured, and at Frenchtown in January, 1813, a number of American prisoners were massacred by the Indians. The British were soon afterward driven out of the territory by Gen. Harrison; and in October, 1814, a truce was concluded with the Indians. The first land surveys entered upon were commenced in 1816, and in 1818 the lands were brought into market for public sale. From this period the prosperity of Michigan properly dates. In 1819 the territory was authorized by act of congress to send a delegate to that body, and the right of suffrage in this case extended to all taxable citizens. In 1819, 1821, and 1836 the Indians made important territorial cessions, and by this time all the lower peninsula and a part of the upper were freed from Indian title. In 1836 Wisconsin territory was formed from the W. portion of Michigan. This region had been annexed to the original territory of Michigan partly in 1818 and partly in 1834. Up to 1823 the legislative power was intrusted to the governor and judges; but in that year congress passed an act transferring it to a council, consisting of 9 persons selected by the president from 18 chosen by the citizens, and the judicial term was limited to four years. In 1825 the council was increased to 13 members selected as before, but two years later the law was so altered that the electors could choose their councillors without the further intervention of the president or congress. In May, 1835, a convention at Detroit formed a constitution by which Michigan claimed a strip of territory also claimed by Ohio. For a time a conflict seemed inevitable, but in June, 1836, congress passed an act admitting Michigan into the Union on condition that she relinquished her claim to the disputed territory, in place of which the region known as "the upper peninsula" was given to her. These conditions were rejected by one convention, but accepted by another in December, 1836; and in January, 1837, Michigan was admitted into the Union. By a legislative act of March 16, 1847, the seat of government was removed from Detroit to Lansing. In 1850 a new constitution was adopted, which with subsequent amendments continues in force. The number of men furnished by Michigan to the Union armies during the civil war was 90,747. The number of those that fell in battle or died of wounds or of disease in the service was 14,823, of whom 337 were commissioned officers. The payments by the state for bounties, premiums for recruits, and other war purposes amounted to $3,784,408; by counties, cities, and townships for the same purposes, $10,173,356 72; by counties for relief of soldiers' families, $3,591,248 12; total, $16,548,992 91.—See "Michigan Geological Survey," by Douglass Houghton (1st-4th annual reports, Detroit, 1835-41); and "Geological Survey of Michigan: Upper Peninsula, 1869-73," by T. B. Brooks, Raphael Pumpelly, and Dr. C. Rominger (2 vols., with an atlas, New York, 1873).

**MICHIGAN, Lake.** one of the five great lakes of the United States, and the only one which is entirely included in these states. It lies in a N. and S. direction, extending from the N. W. corner of Indiana and the N. part of Illinois about 320 m. to Mackinaw, where it communicates with Lake Huron by a strait 4 m. wide in its narrowest part. The lake is bounded E. by the lower peninsula of Michigan. The upper peninsula bounds it N. W. In this portion is Green bay, which extends S. into Wisconsin; this state and Illinois complete the western boundary of the lake. The following are its dimensions as given by Dr. Douglass Houghton: length, 320 m.; mean breadth, 70 m.; mean depth, 1,000 ft.; elevation above the sea level, 578 ft.; area, 22,400 sq. m., exceeding the area of Lake Huron by nearly 2,000 sq. m. The country around Lake Michigan is for the most part low and sandy; on the E. side particularly the sands thrown up by the waves are blown inland and form hills, which sometimes are 150 ft. high. The rocks are the limestones and sandstones of the sub-carboniferous groups, lying in horizontal strata, and never rising into bold cliffs. On the Michigan side they belong chiefly to the Portage and Chemung groups, and on the Illinois side to the Fieldberg limestone. Along the southern shores are post-glacial beds of clay and sand lying a few feet above the level of the lake. Containing fresh-water shells like those living in its waters. This fact and the low watershed that separates the lake from the valley of the Illinois river, together with the great capacity of this valley, which appears as if worn by a mighty river, render it probable that the waters of Lake Michigan at some period found their way by the valley of the Mississippi into the gulf of Mexico. The lake at present is believed to be moving westward, gradually encroaching on the shores of Wisconsin and leaving those of Michigan. The existence of a lunar tidal wave was determined by the observations of Lient. Col. James D. Graham at Chicago in 1858. The mean of 340 observations shows a difference of elevation of the lake surface between high and low water of 153 thousandths of a foot; and the mean of 24 semi-diurnal spring tides (i. e., one day before and two days after new or full moon) gives a difference of elevation of
245 thousandths of a foot, or a little over 3 inches. High water occurs half an hour after the meridian passage or southing of the moon.

This lake has few harbors and bays, and the only islands it contains are at its N. E. extremity. It is not therefore very safe to navigate, especially as it is subject to severe storms at different seasons. But there is a large traffic on it, between Chicago and the lower lake ports. The straits of Mackinaw, which longest retain the ice, are usually open between May 1 and Dec. 1. The fish of the lake are like those found in Lake Huron, and the fisheries are for the most part concentrated about Mackinaw. The best harbors are at Little Traverse bay, and at Grand Haven at the mouth of Grand river on the E. shore of the lake. Chicago, near the head of the lake, has but an indifferent harbor, and the same may be said of those of Milwaukee and Sheboygan on the W. side.

MICHIGAN, University of, an institution of learning at Ann Arbor, which owes its foundation to a grant of lands by congress in 1826 to the territory of Michigan, including two townships containing 72 entire sections, which on the admission of the state were conveyed to it for the support of the university. The present institution was established by a legislative act of March 18, 1837. It was first opened for students on Sept. 20, 1842. The university consists of three departments: the department of literature, science, and the arts; the department of medicine and surgery, organized in 1850; and the department of law, 1859. Each has its own faculty of instruction, while the university senate is composed of all the faculties. The department of literature, science, and the arts embraces six regular courses of four years each, and two shorter special courses. The regular courses, with the degrees that are conferred upon their completion, are as follows: classical (bachelor of arts), scientific (bachelor of science), Latin and scientific (bachelor of philosophy), Greek and scientific (bachelor of philosophy), civil engineering (civil engineer), mining engineering (mining engineer). The special courses are one in analytical chemistry and one in pharmacy. On the completion of a two years' course in pharmacy the degree of pharmaceutical chemist is conferred. Students may also pursue selected studies for any period not less than one term. Post-graduate courses are provided for graduates of the university or of any other collegiate institution who may desire to pursue advanced studies, whether for a second degree or not. The regular course in the medical department is two years. Students have the advantages of clinical instruction in a well arranged hospital on the university grounds, under the charge of the faculty. In the law department the degree of bachelor of law is conferred upon candidates 21 years old and upward, who have completed the course of two years and have passed a satisfactory examination. A year's course in another law school, or one term's practice of law under a license from the highest court of general jurisdiction in any state, is accepted as an equivalent for the first year in this institution. The degree entitles the holder to an immediate license to practise in all the courts of Michigan. Candidates for admission to the academic department must be at least 16 years of age, and to the law department 18. Both sexes are admitted to all departments, but the courses of lectures for women in the medical department are distinct from those for men. Students before entering any department are required to pay a matriculation fee of $10 if residents of Michigan, and of $25 if resident elsewhere. There is also an annual payment of $15 for residents of Michigan, and of $20 for students from other states or countries. The members of faculties and other officers of the university in 1873-4 numbered 44, viz.: president, 1; professors, 23; librarian, 1; assistant professors, 6; lecturers, 2; instructors, 8; assistants, 8. The faculty of the department of literature, science, and the arts embraced 14 professors, 6 assistant professors, and 9 other instructors; medical faculty, 8 professors, 2 lecturers, and 1 other instructor; law faculty, 4 professors. The number of students in the department of literature, science, and the arts was 484, of whom 52 were females, viz.: resident graduates, 9; seniors, 70; juniors, 96; sophomores, 90; freshmen, 118;
in selected studies, 33; in pharmacy, 68. Of those in the regular courses, 175 were pursuing the classical, 76 the Latin and scientific, 90 the scientific, and 83 the engineering course. The number of students in the medical department was 314, of whom 34 were females; in the law department, 514 (124 seniors and 190 juniors), of whom 5 were females; whole number in the university, deducting repetitions, 1,106.

The number of degrees conferred at commencement in 1873 was 329, viz.: pharmaceutical chemist, 9; civil engineer, 11; bachelor of science, 12; bachelor of philosophy, 15; bachelor of arts, 40; doctor of medicine, 91; bachelor of law, 123; master of science in course, 8; master of arts in course, 19; master of arts on examination, 1. According to the last triennial catalogue, published in 1871, the whole number of alumni was 2,900, of whom 2,758 were living. The libraries accessible to the students contain about 50,000 volumes. These are the university library, 22,000; medical library, 1,500; law library, 3,000; and the libraries of two literary societies in the department of literature, science, and the arts, and of the Christian association connected with the university. The university museum contains valuable and constantly increasing collections, illustrative of natural science, ethnology, art, history; agriculture, anatomy, and materia medica. The geological cabinet contains about 14,000 distinct entries and 41,000 specimens, including a large and complete series of lithological and palaeontological specimens obtained through the state geological surveys; the zoological cabinet, 11,500 entries and more than 45,000 specimens, including a complete series of the birds that visit Michigan, with most of the mammals of the state, a nearly complete series of the reptiles found E. of the Rocky mountains, 2,000 species of mollusca, and a considerable collection of fishes and radiata; the botanical cabinet, 9,000 entries, 5,000 species, and 45,000 specimens, including a collection of Alaskan plants, and 1,500 entries, 1,153 species, and 3,000 specimens of the plants of Michigan. The mineralogical cabinet embraces a valuable collection of the minerals of the state, and a collection of more than 6,000 specimens, chiefly European, purchased of the late Baron Lederer. The collections in the department of fine arts and history embrace a gallery of casts of the most valuable ancient statues and busts, a gallery of engravings and photographic views executed in Italy and Greece, a collection of historical medallions, &c. In the department of archaeology and relics the collections embrace among other specimens various articles of domestic and warlike use among the American Indians and the islanders of the South Pacific. The astronomical observatory, erected by citizens of Detroit, was opened in 1854. The building consists of a main part, with a movable dome and two wings. It contains a fine large meridian circle, a sidereal clock, two collimators; a chronograph, with Bond's new isodynamic escape ment, for recording observations by the electro-magnetic method; and a refracting telescope, with an object glass 18 inches in diameter. The university grounds embrace 44⅔ acres. Besides the observatory, there are a central building, called University hall, for the department of literature, science, and the arts; buildings for the departments of law and medicine; a chemical laboratory, and residences for the president and professors. The entire cost of the buildings was about $230,000. University hall has a front of 347 ft., with a depth in the centre of 140 ft. and on the wings of 40 ft.; height from the basement to the summit of the dome, 140 ft. In the front of the second story there is a well arranged auditorium, with settings for 3,000 persons. The receipts into the treasury for the year ending June 30, 1875, including $29,325 46 on hand at the beginning of the period, but not included in the proceeding year, and $1,985 52, of which $38,667 was received from the state on account of the university interest fund, $28,000 from special state appropriations, $23,005 from students' fees, and the rest from miscellaneous sources. The expenditures were $107,416 51, of which $73,392 16 was for salaries and janitors' wages, $2,250 for libraries, the rest for various purposes; balance, $17,051 71. The university fund, being the proceeds of the sale of the university lands, amounts to $543,010 24. It is held in trust by the state, which pays interest thereon at the rate of 7 per cent. per annum. The university is under the control of a board of eight regents, who are elected by the qualified voters of the state for a period of eight years, two retiring every two years. They choose the president of the university, who is ex officio a member and president of the board. Previous to 1852, under the regulations then in force, there was no president of the university. Since that time the office has been filled as follows: Henry P. Tappan, D. D., 1852-'63; Erastus O. Haven, D. D., 1863-79; Henry S. Frieze, LL. D. (acting), 1869-71; James B. Angell, LL. D., appointed in 1871 and still in office.

MICHIGAN CITY, a town of Laporte co., Indiana, on the S. shore of Lake Michigan, at the mouth of Trail creek, 140 m. N. by W. of Indianapolis, and 40 m. E. S. E. of Chicago; pop. in 1860, 3,320; in 1870, 3,985. It is the principal lake port of the state, and is at the intersection of the Michigan Central, the Louisville, New Albany, and Chicago, and the Indianapo lis, Peru, and Chicago railroads. Its trade is considerable. The Michigan Central railroad has here extensive repair and locomotive shops. The town is the seat of the northern state prison, and contains a national bank, a high school, and ten other public schools, a weekly newspaper, and seven churches.

MICHILIMACKINAC. See Mackinaw.

MICHOACAN, or Mechoacan, a maritime state of Mexico, bounded N. by Jalisco, Guanajuato, and Queretaro, E. by Mexico, S. by Guerrero,
S. W. by the Pacific, and W. by Colima and Jalisco; area, 21,609 sq. m.; pop. in 1868, 618,340. The face of the country is extremely mountainous, being traversed in every direction by the Sierra Madre and its branches; there are several peaks of considerable elevation, especially in the S. portion, where, among other volcanoes, is that of Jorullo. (See Jorullo.) The culminating point is the Cerro de Santa Rosa, in the district of Tlapujahua, about 17,000 ft. Between the ridges stretch elevated and fertile valleys, watered by several rivers, the principal of which are the Lerma and Mescala or Balsas, and a great number of mountain torrents. Of the 11 lakes, those most noteworthy are Chapala, about 60 m. long by 20 m. in width; and the Pátzcuaro, 30 m. in circumference. Along the coast line, 100 m. in extent, the only ports are those of San Telmo, Buceria, and Maratua; the first was formerly open to foreign and coasting trade, but did not prosper owing to the want of suitable shelter for shipping. Michoacan has a great variety of climates, from extreme cold to excessive heat; but it is in general very healthy. The mean annual temperature at Morelia is 71° F. The mineral productions are silver with an admixture of gold, copper, cinnabar, iron, coal, lead, emery, sulphur, coppers, lithographic stone, marble, &c. The mines, now comparatively few, yield annually $1,175,300, of which silver is about one third. The soil, wherever accessible, is extremely fertile; maize in most parts yields 400 fold. Cattle, horses, mules, asses, and hogs are extensively reared; and the lakes and rivers abound in excellent fish, the taking of which forms an important industry. Among the manufactures are rebozos, sarapes (Mexican shawls), blankets, and silver vessels of various kinds; and there are numerous flour mills, a glass factory, and in Morelia a steam weaving factory. The exports embrace gold, silver, copper, cabinet and dye woods, coffee, indigo, and silk, mostly sent to the states of Mexico, San Luis Potosi, and Durango, and to Guatemala. There are good roads in the state; and in 1873 Morelia was placed in communication with the principal telegraph lines of the republic. The value of real estate in 1869 was estimated at $18,498,351 10; and the government expenditure in the same year was $589,217 60. Michoacan has a state college, 55 schools for males and 28 for females, with an attendance of 11,426. There are several benevolent institutions. The state is divided into 17 districts. The capital is Morelia (formerly Valladolid); and the chief commercial towns are Morelia, Puruándiro, Zamora, Ario, Zacambaro, and Taréan.

MICIPSA. See JEGUERTIA.

MICKIEWICZ. Adam, a Polish poet, born in Novogrodek, Lithuania in 1798, died in Constantiâpe, Nov. 27, 1855. He studied physics and chemistry at the university of Wilna, but finally devoted himself almost exclusively to literature and poetry, and became professor of literature at Kovno. In 1822 he published at Wilna two small volumes of poetry, afterward augmented, which contained some of the finest ballads in the Polish language, a historical epic, Grafsyno, and under the title of Dziady a romantic autobiographical drama. This publication raised Mickiewicz to the highest rank in Polish poetry. He was idolized by the revolutionary youth of Poland, particularly after he was tried for participation in the secret associations of Zan, imprisoned in the Basilian convent at Wilna, and finally condemned in 1834 to perpetual banishment from his native country. He was removed to St. Petersburg, where he became familiar with the most distinguished Russian liberals, and subsequently to Odessa, whence he was allowed to make a tour through the Crimea. This he partly described in his "Sonnets," which were followed by his second epic, Wallerrod, published in 1828 at St. Petersburg, whither he had received permission to return. This poem, the theme of which is the struggle of the Lithuanians in the 14th century against their oppressors, the Teutonic knights, was favorably received in Russia, being also translated into the Russian language, and the author was even allowed to enter upon a tour through Germany and France to Italy for the restoration of his health. At Rome he received the news of the outbreak of Nov. 29, 1830; but he did not reach the confines of his native country until the struggle had ended, and he never again entered Poland. He went to Dresden, and there wrote the second part of Dziady (Paris, 1832), in which he described his imprisonment and the cruelties perpetrated by Russian tyranny on Poland. His next publication was Kréjg narodu polskie w pielgrzymce polskiej ("Boys of the Polish Nation and the Polish Pilgrimage," 1832), which was followed by another poetical work, Pan Tadeusz ("Sir Thaddeus," 1834), a picture of Lithuanian life and society in 1812 at the approach of Napoleon's invasion. He had lived for some years in Paris when in 1839 he accepted a professorship of classical literature at Lausanne; but in a year he returned to Paris to fill the chair of Slavic literature in the collège de France. He was now known as a zealous advocate of Roman Catholicism, from which he hoped for a regeneration of his country, as well as of Pan-Slavic tendencies, which were not shared by all of his fellow exiles. His "Lectures on Slavic Literature," published both in French and German, gradually developed still more surprising phases. The inspiring genius of the poet was now a fanatical Polish priest, Towlanski, who had mesmerized him. Mickiewicz in a dangerous illness in 1841, from which he recovered, and who, pretending to be enlightened by celestial visions, was followed by Mickiewicz as the Messiah of a new religion, in which the memory of Napoleon received almost divine honors. In order to gain over
PIUS IX. to his schemes of national regeneration, he went to Italy in 1848, and at Florence received a flattering ovation. In 1851 he was appointed by Louis Napoleon sub-librarian of the library of the arsenal at Paris; and on the outbreak of the war against Russia he headed a Polish deputation to the French emperor, calling upon him to turn the great movement in favor of their oppressed country. Soon after he was sent on a secret mission to Constantinople, where he ended his career. His works have passed through numerous editions, and have been partly translated into other languages. His correspondence has been published in Paris (3 vols., 1870 et seq.).

MICKLE, William Julius, a Scotch poet, born at Langholm, Dumfriesshire, Sept. 29, 1734, died at Wheatley, Oxfordshire, Oct. 25, 1788. After pursuing various occupations and becoming bankrupt, he became in 1768 corrector of the Clarendon press at Oxford, and produced "Pollio," an elegy, and "The Concubine," a moral poem, the title of which was afterward changed to "Syr Martyn." He published a translation of the first book of the "Lusiad" in 1771, and in 1775 completed the work which has passed through many editions. His most popular productions are "Cumnor Hall," which suggested "Kenilworth" to Scott, and the song "There's nae luck about the house," the authorship of which has been disputed.

MICMACS, the most easterly branch of the Algonquin family of Indians, spread over northern New Brunswick, Nova Scotia, Cape Breton, Newfoundland, Prince Edward Island, and Gaspé. They were called by the early French writers Souriquois, and by the neighboring Indians "Salt Water Indians," as they always cling to the seacoast. The Indians taken to England by Cabot in 1497, and to France by Aubert in 1508, were apparently Micmacs. From a very early period they waged fierce war with the Little Esquimaux north of the St. Lawrence. They were expert canoe men, and lived by fishing and hunting. They knew maize and tobacco, but there was no cultivation of maize among them, or indeed east of Saco. When the French under De Monts began to settle Canada, the Micmacs were estimated at 3,000 or 3,500, and their greatest chief was Membertou, who is said to have seen Cartier. Missions were soon begun, and the French secured permanently the friendship of the Micmacs. They figure in many of the border wars, and after the English established Annapolis, the Micmacs destroyed Capt. Pigeon's force at Bloody Creek in 1711. They constantly plundered English vessels on the coast, in 1722 taking several in the bay of Fundy, and 18 in the harbors. They cruised along in their prizes, and actually engaged two British armed vessels sent out against them. They attacked Annapolis in 1724 and 1744, Port Lajole in 1746, and the fort at Mines in 1749, capturing a lieutenant and 18 men; and in 1751 they took Dartmouth, opposite Halifax. Band after band made peace, but it was not till 1760 that the Richibucto Micmacs, the most warlike and formidable, laid down their arms. A series of treaties followed, and the Micmacs submitted to English rule. From 1783 to 1841 reservations were allotted to them in New Brunswick, and in other colonies attempts were made to induce them to become agricultural; but they were strongly averse to it, and in 1844 New Brunswick began a series of acts for selling the land. Nova Scotia and Cape Breton did the same, investing the proceeds for the benefit of the Indians. Catholic missions have existed among them from early times, and Protestant missions have been actively maintained for several years past. In 1873 the Micmacs were estimated at 1,765 in Nova Scotia, and 1,386 in New Brunswick; there were 400 on Cape Breton in 1881, and 70 in Newfoundland; so that they are about as numerous as they were 270 years ago. The Micmacs worshipped the sun. Papkootaparout, the governor and ruler of the land of souls, was their great benefactor, having given them corn and tobacco. Gloscape is another great mythical character. Le Clerq, toward the close of the 17th century, found at Gaspé great reverence for the cross, and many theories were based on the fact; but Lescarbot many years before mentions their setting up crosses in imitation of the French. They made no pottery, had no hemp like neighboring tribes, made breech cloths and mantles of skins, strings for bows and fishing lines of intestines, and lodges of bark or skins. They had a system of hieroglyphics more comprehensive than has been found in other northern tribes. Le Clerq, seeing boys take down the prayers he was teaching them, adopted and improved these hieroglyphics, and as finally established they are still employed. Three books in this character have long been in use among them in manuscript, and one was recently printed at Vienna. A grammar of the Micmac language, by the abbé Maillard, revised by Bellenger, was printed at New York in 1864; and portions of Scripture, tracts, and books of devotion have been printed in the language, some in phonetic characters and some in ordinary type.
MICROMETER (Gr. μίκρος, small, and μέτρον, measure), an instrument applied to telescopes and microscopes for measuring minute spaces and objects.—Telescope Microscopes. A paper by Mr. Townley in the "Philosophical Transactions" for 1667 describes a micrometer with a movable wire which was constructed by a Mr. Gascoigne in England about 1640, and used by him in measuring the diameter of the moon and some of the planets. Gascoigne was killed in the civil wars in 1644, and as he left no account of his invention, it only became known through Mr. Townley, into whose possession one of the telescopes had fallen. This instrument was afterward improved by the celebrated Dr. Hooke, who is said to have added parallel hairs. A similar micrometer was afterward made by Azout, and another by the marquis of Malvasia. The instrument now in use under the name of the filar micrometer is constructed upon the same principles as either of the above, and may be understood by referring to figs. 1 and 2, drawn from instruments by Troughton of London. Fig. 1 represents a section transverse to the axis of the telescope. Two forks, k and l, are moved in a plane perpendicular to the axis of the telescope by means of the fine micrometer screws o and p. Each of these forks has stretched across it a spider’s web which is placed in the focus of the objective. These webs are parallel, and being made to embrace any object, as the disk of a planet or the distance between two stars, the number of turns of the screws, which may be read by the graduated circles u u, will indicate the space measured, the value of a revolution of the screws having been ascertained by the time occupied by a known star in passing from one line to the other when placed at the distance of a certain number of revolutions, or by the measurement of some known space. Another web is stretched across the centre of the field, perpendicular to the other two. The position of these lines may be revolved about the axis of the telescope by means of the endless screw attached to the box holding the spider webs, turns by means of the fixed toothed circle g h. The instrument is used as follows. Suppose it is desired to measure the angles of position and distance of two stars. The telescope is set on the objects, and the screw sx is turned until the line s t bisects the two stars. The milled heads m m are then turned until the webs carried by the forks bisect each a star. The distance is indicated by the number of revolutions and parts of revolutions of the screws which separate the movable lines. The position is ascertained by a comparison of the reading of the position circle, g h, with its reading of the zero of position, which is when the lines are so placed that the image of a star will traverse the field from side to side, bisected by one of the lines, the telescope being at rest and the star passing by the diurnal motion of the earth. A modification of the filar micrometer is the most useful and accurate adaptation for reading the divisions on the limbs of large astronomical and geodetic circles. Huygens used a micrometer which employed a circular diaphragm in the focus of the eye glass, and whose angular value was ascertained by the time it took a star to pass across it. By using wedge-shaped plates of brass, some part of which exactly covered the disk of the planet, its diameter was found by a comparison with the size of the aperture. Fraunhofer’s suspended annular micrometer is an ingenious, accurate, and convenient instrument, much used for objects, such as comets, faint stars, and asteroids, which will not bear the illumination necessary to render visible the lines in a filar micrometer. It is shown in fig. 3, and consists of a disk of plate glass having in its centre a round hole about half an inch in diameter, to the edges of which a ring of steel is cemented, and afterward turned true in a lathe. When the disk is mounted in a brass tube and adjusted in the focus of the eyepiece of the telescope, the steel ring is alone visible, and appears as if suspended in the atmosphere. It is used to establish the position of an unknown object by comparison with one whose place is known, the transits of each being taken by turns, as it passes across the ring.—There are several other forms of micrometers, constructed upon various principles, and with reference to particular uses. The more important of these are the double-image micrometers, in which two single refracting lenses or semi-lenses are made to produce double images. When the centres of two images of the sun, moon, or any of the planets are superposed so that the disks touch each other, the separation of the lenses will indicate the diameter of the object. Roemer is said to have been the first to suggest such an instrument, which had two whole lenses.

FIG. 3.
Dollond's improvement consists in placing two half lenses side by side upon a sliding frame, and was called the divided object-glass micrometer. Other double-image micrometers are made of double-refracting crystals. This invention is ascribed to the abbé Rochon, rock crystal being the substance preferred by him on account of its transparency and hardness. Arago employed Rochon's micrometer in taking more than 3,000 of the diameters of the planets. A micrometer with double images was devised by Porro of Paris in 1842, which consists of a parallel plate of glass placed within the telescope so that part of the rays from the object pass through it and another part beyond it. An inclination of the plate will produce two images of the object, whose diameter may be measured by the amount of rotation given to the glass to produce certain alterations in the position of the image. A recent method for taking the positions and distances of stars, double or in clusters, is to photograph the telescopic field in collodion on glass, and then to measure the impression on the stage of an independent micrometer constructed for the purpose. The great advantages of this method are that all the careful micrometer work can be done by an assistant who is not a professional astronomer; that it can be done during day or night, and repeated at will, the photographs being imperishable; and that when done it is most accurate. An instrument of this kind, which has undergone several stages of improvement, was designed and constructed by Lewis M. Rutherfurd of New York several years ago. A sketch of the instrument as now in use at his private observatory is given in fig. 4. It stands upon a tripod, which may be accurately levelled by the milled head screws attached to the feet. The photographic plate, p, to be measured (five inches square), is clamped upon the circular glass stage e, which is supported by and revolves with the graduated position circle q, the verniers being read by the reading glasses h h. The compound microscope a is directed perpendicularly to the plate, and can be moved in two directions at right angles to each other and parallel to the plate, on the slides e and d. The quantity of such movement is read by the microscopes e and b upon glass scales of equal parts, m. (The scale read by b is not seen in the figure.) The fractions of a division are read by the filar micrometer seen at the eye piece of a. The eye piece of the microscope a contains a cross of spider lines by which it is centred upon the image of any star to be measured.—Microscope Micrometers. Most telescope micrometers may be used for microscopes when the eye glass has considerable focal length. Objects of known diameter are used, as lycopodium seed, or wire whose diameter has been measured by winding it many times around a cylinder, and dividing the length of the cylinder by the number of turns. A convenient micrometer was constructed by Dr. Wollaston, consisting of a scale, fig. 5, made of wires \( \frac{1}{4} \) in. diameter, which occupies the place of the object, and a lens of about \( \frac{1}{4} \) in. focal length in the cap of the instrument. The object, placed beneath this between two glass slides, is moved laterally across the field by means of the milled head a. (See Microscope.)

**MICRONESIA AND MELANESIA**

(Gr. \( \mu \)ικραν, small, \( \mu \)ι\( \lambda \)ας, black, and νη\( \phi \)ς, island), terms derived from the size and complexion of the inhabitants, and applied by some geographers to arbitrary divisions of the islands of the Pacific ocean. These divisions are both comprehended in the better defined, more convenient, and better understood terms Australasia.
and Polynesia. Micronesia and Melanesia occupy the western portion of the Pacific. The former extends from the westernmost island of the Hawaiian group to near Japan and the Philippines, and reaches S. of the equator, comprehending the Marshall and Gilbert groups, the Ladrones, and the Carolines. Melanesia embraces the Feejee islands, the New Hebrides, Solomon’s islands, New Caledonia, New Britain, New Ireland, and Papua.

MICROSCOPE (Gr. μικρός, small, and σκοτεινός, to see), an optical instrument for the examination of minute objects. Microscopes are of two kinds, simple and compound. With the former, the object is viewed directly, either by means of a single lens or a set of lenses employed in the same manner as a single lens. With the latter, an enlarged image of the object is formed by a single lens or a set of lenses, termed the object glass or objective; this image is viewed and further amplified by means of an eye piece or “ocular.” Each form is valuable in its place, but as a general instrument of research the compound form, with all the modern improvements, is greatly superior. The invention of the simple microscope is not claimed by any one, but that of the compound has been warmly disputed; it is claimed by the Italians and the Dutch. The compound microscope of the present day, however, is a very different instrument from the disputed invention, and to this last and best form we purpose to devote the most of our attention. The earliest magnifying lens known, if indeed it was used for this purpose, is the rude one found by Mr. Layard in the palace of Nimrud; it is made of rock crystal, and is far from perfect. Seneca (Quaestiones Naturales, lib. i., cap. vi.) alludes to the magnifying power of a glass globe filled with water; he ascribes the effect to the water, and appears to refer to objects immersed in the water; this was about the middle of the 1st century. “Burning spheres,” as they are termed by Aristophanes, were sold in the shops of Athens in his day, about 400 B.C. There is no evidence that lenses were employed at this early date for magnifying, at least otherwise than as reading glasses. It is not until the 17th century that we find powerful magnifiers of glass actually employed for scientific investigation. The names of Malpighi, Lieberkühn, Hooke, Leuwenhoek, Swammerdam, Lyenetz, and Ellis are closely connected with the history of the simple microscope; and their important discoveries attest the value of even this form of the instrument. Most of the magnifiers employed by the early observers were minute single lenses of glass; often small spheres formed by melting threads of glass in the flame of a spirit lamp. The small single lenses of high power are usually plano-convex, the plane side toward the object; when carefully made, having a focal length of from \( \frac{1}{3} \) to \( \frac{1}{2} \) of an inch, and well set in shallow blackened cells, with the proper aperture, they perform on ordinary objects tolerably well; much better than the minute glass spheres, as the latter are difficult to obtain free from bubbles. The writer has succeeded better by melting a fragment of plate glass in a small hole in a German silver cup, by means of the blowpipe, and has formed lenses in this way, ready mounted for use, quite equal to those ground and polished by hand. The German silver is blackened by the heat. In order to diminish the spherical aberration in the high magnifier of a single refracting substance, Sir David Brewster suggested the employment of gems; and Mr. Fritchard of London, under the patronage of Dr. Goring, ground lenses of garnet, sapphire, and diamond, all of which proved superior to glass lenses of equivalent focus. The diamond lenses upon the whole were inferior to the sapphire; the latter, though not as highly refractive, were free from the veins which rendered several of the diamond lenses useless, though still affected, in common with the diamond, by double refraction. The garnet lenses are free from this latter defect, and when very minute are much superior to glass; the color is not objectionable when the lenses are very small. All the magnifiers composed of single lenses, glass or gems, are surpassed by the doublets and triplets. The invention of the doublet in its best form is due to Dr. Wollaston; it appears, however, to have been a chance discovery. It consists of two plano-convex lenses, having their plane sides toward the object; the posterior lens (that nearest the eye) is three times the focal length of the anterior, and the distance between them is twice the focal length of the shorter. It is evident that the front lens of the doublet must be approached much nearer to the object than if it had been used alone, and the amplification is also less than that of the front lens alone; hence the working distance is much less than that of an equivalent single lens. The great and surpassing advantage of the doublet is the enlarged angle of aperture and diminution of spherical aberration. By “angle of aperture” is meant the angular breadth of the cone of rays proceeding from the object, and refracted through the lens or set of lenses. Evidently, with a single lens, having an aperture equal to its focal length, the angle will be about 55°; in other words, the lines drawn in the same plane from a point to the margin of the lens, this point being in the axis of the lens, and at a distance from its convex surface equal to the diameter of the lens, will be 55°; no single lens, however, will admit anything like this aperture. In the doublet the front lens is approximated much closer to the object than it possibly could be if employed alone, and hence it admits a wider angle; the reduction of magnifying power, at the same time, diminishes spherical aberration, which is still further reduced by the peculiar relations of the curvatures. The doublet thus becomes a very superior instrument, and, when well made and
Microscope
carefully used, surpasses all but the most improved forms of the compound instrument. Doublets of gems are far superior to those of glass. Triplets are superior to the doublets; and for a simple microscope the achromatic triplets now furnished by the French and German opticians, as objectives for the compound microscope, will be found very effective. Essentially, the English and American achromatic objectives are triplets, but the peculiar mounting of these instruments prevents their use as simple microscopes. So great has been the improvement, that the best modern objectives will transmit angular pencils of 170° to 178°. We may notice here the so-called "Coddington lens," or grooved sphere. It is an invention of Sir David Brewster, and when properly made is almost free from spherical aberration, and the chromatic aberration is almost insensible. "It consists of a spherical lens, or sphere with a deep concave groove cut round it, so as to cut off the marginal pencils, and thus give a wider field and more perfect image." The lenses usually sold under this name are simply cylinders of glass having spherical ends, and of course have none of the advantages of large field and freedom from spherical aberration proposed by Dr. Brewster. When the curvatures of this cylindrical lens are unequal, and such that, the most convex being turned toward the eye, an object placed on the other convex surface is in the proper focus of the lens, it is called a "Stanhope lens:" its use is limited to such objects as can be directly applied to the surface. When of considerable power it may be advantageously employed in searching for diatomaceae; the drop of water supposed to contain them may be examined by applying it to the less convex surface.—All the simple microscopes, and especially the higher powers, require some kind of a stand or carrier. The lower powers and single lenses are usually attached to the end of a jointed rod, which can be moved up and down a stem inserted into a solid base. The most convenient mounting for an inch or half-inch lens, for preliminary examinations or botanical dissections, is that of Messrs. Powell and Lealand of London, and is employed as the mounting of the small condenser for their compound instrument. The movements are complete, and one can place the lens, whatever may be the position of the object, in such a relation to it as will insure the best view. For the higher powers, $\frac{1}{4}$ to $\frac{1}{2}$ of an inch, a steady well made stand will be required, and some means of adjusting the focus delicately, either by rackwork or screw. Various forms have been devised; perhaps, upon the whole, that known as the "Raspail" is most simple, and at the same time of great excellence. It consists of a brass pillar, up and down which a large circular stage is moved by rackwork; a large mirror, one side plane, the other concave, swings freely below, and serves to direct the light upon the object; at the top of the brass pillar is placed the lens holder, movable forward by means of a screw, and laterally by swinging round a pin inserted in the top of a pillar; into the opening of the stage is fitted a glass plate, or it may be made to hold dissecting troughs with glass bottoms. It is often convenient, or absolutely necessary, for the examination and dissection of opaque objects, to have the lens inserted in a silver cup or Lieberkuhn, which, receiving the light from the mirror below, reflects it back, condensed, upon the object. These Lieberkuhns are usually made of silver. The very simple microscope employed by Ellis in his research on coralline, in which all the adjustments were effected by sliding by the hand, was fitted with these silver cups. Although the Lieberkuhn is very commonly applied to the low power achromatic objectives, it is now seldom to be obtained with any form of simple instrument, unless by special order; it will be found of the greatest service in minute dissection.—In using lenses of moderate focus, three fourths to one eighth inch, the most extended distinct field is obtained when the convex side is presented to the object; but the sharpest vision of a minute point or small object, in the centre of the field, is when the flat side is presented to the object. In estimating the magnifying power of single lenses, an arbitrary standard of the nearest distance at which the healthy unassisted eye can view distinctly minute objects is assumed; this distance has been placed at from 5 to 10 in. The latter is the standard adopted by most opticians and authors; Sir David Brewster alone adopts 5 in. The magnifying power is obtained by dividing 10 in. by the solar focal length of the lens, and is usually expressed linearly, or as "so many diameters." Thus, when the magnifying power is stated to be 40, it is meant that the diameter is increased 40 times, but the area would be increased 1,600 times. The following table exhibits the linear and superficial magnifying power, adopting the standard of 10 in.:
The proportion between the two images so seen will be the focal length required. The panes of glass in a window, or courses of bricks in a wall, are convenient objects for this purpose. The comparative force of two lenses, or sets of lenses, may be determined by holding them at the same distance from the eye and estimating the size of the image formed by each of the same object; thus, if one lens forms the image half the size of the other, linear measure, its focal length is half that of the other. The same method applies to eye pieces.—For a history of the earlier forms of the compound microscope, the reader may consult the elaborate works of Quekett and Harting and the older works of Adams and Baker. Essentially it consists of two parts, the object glass and the eye piece. The former is now made by a combination, usually, of three sets of achromatic doublets, arranged to give the greatest freedom from spherical and chromatic aberration; the latter, of two plano-convex lenses, with the plane sides to the eye, the lens nearest to the object, or "field lens," being almost exactly double the focal length of the eye lens, and the distance between them a little more than the focal length of the field lens; the ratio is varied somewhat by different makers. In fig. 1, the object placed at P, on the stage T, is illuminated by converging rays, b, b, b, b, reflected from the mirror S. At L is the compound achromatic object glass. C is the field lens, and A the eye lens of the eye piece. With the eye lens one views the image of the object, P, formed by the object glass. The eye piece thus formed is termed a "negative eye piece," or the "Hygogenean." The eye piece of Kellner is a decided improvement; it is termed "orthoscopic," and the eye lens is achromatic or nearly so; these eye pieces are supplied by the Messrs. Grunow of New York, with their best instruments; the field of view is large, free from distortion, and well defined throughout the whole extent. The orthoscopic eye piece supplied by Mr. Charles A. Spencer of Canastota, N. Y., and more recently as improved by R. B. Tolles of Boston, has both eye and field lens achromatic, and is exceedingly perfect; it is, however, more expensive than the Kellner eye piece. Mr. Tolles has introduced a 'solid, orthoscopic, negative eye piece, of remarkable clearness and definition throughout, especially fitted for micrometric use, the engraved scale being cemented in the body of the solid eye piece, and perfectly protected from all dust or interference with definition, so noticeable in the use of the eye-piece micrometer in the ordinary way. Mr. Tolles has also introduced what is termed an amplifier, being an achromatic concave of peculiar construction, which is introduced within the body of the microscope by means of an adapter. The corrections of the objective are not in the least disturbed by this arrangement, but the power is doubled. A low eye piece thus gives as much amplification as a higher one, and with the great advantage of almost perfect flatness of field. The object glasses, or "objectives" as they are now very commonly termed, derive their denominations, 1 inch, ¾ inch, ⅔ inch, &c., from the fact that the combined sets of lenses give a magnifying power the same as a single lens of the same name. Thus, a ½ object glass should give the same amplification as though a single lens of ⅔ inch was used in its place. This term does not refer at all to the working distance, for, as is the case with doublets, the working distance with all powers higher than ⅔ inch is considerably less than that of the equivalent single lens; it will be apparent that for any given focus the working distance will, in general, be diminished by an increased angle of aperture; a ½ of 90° will have in this respect a very great advantage over a ¼ of 140°. As regards the merits of the large angle objectives, there are various opinions. Dr. Carpenter is decided in his condemnation, considering that depth of penetration cannot be had at the same time with enlarged angle. The skill of the first opticians, Spencer, Tolles, and Wales in America, Ross, Powell and Leeland, and Smith, Beck, and Beck in England, have proved the contrary. Nor is Sir David Brewster's assertion true of large angle objectives, that they give a distorted view. The definition, clearness, and perfectness of vision with Powell and Leeland's ¾, having an angle of 176°, when employed with a low eye piece so as to give the same amplification as a ¼ with a higher, is greatly superior to that of the ½. The chief advantage of the small angle has been considered to be the sort of general view it would give of the whole of a minute object; the working distance being so great that the minute elevations and depressions in the object itself, being but a very small fraction of the whole distance, would not perceptibly affect the focus. In many respects this might be a desirable quality; but the microscopist would quite as often find it a source of error in his interpretation of what he might observe, and he will find it safer to decide as to the elevations and depressions of an object by the removal and approach required to be given to the object glass.
in order to bring successively these elevations and depressions into distinct view. In minute and elaborate investigations the high angle objectives are the most trustworthy. Moreover, the skill of the opticians named has enabled them to increase the angle without diminishing so very much the working distance. The \( \frac{r}{g} \) of Mr. Ross, and we believe the \( \frac{r}{g} \) of Powell and Lealand, will work through glass \( \frac{r}{g} \) of an inch thick.—In speaking of the objectives of the prominent makers, we do not desire to indicate any order of precedence; they are all excellent, and all have peculiarities of their own. We must, however, be permitted to notice a little more fully the American artists. The oldest optician, and the one who has been most known in connection with the microscope in the United States, is Mr. Charles A. Spencer of Canastota, N. Y. The object glasses furnished by him, particularly the later ones, are of the highest order; they range from 3 in. to \( \frac{1}{2} \) in. By many of our most experienced microscopists they are considered superior to the best objectives of the London opticians; they are certainly equal to them. Mr. Spencer, in the earlier days of high angle objectives, no doubt surpassed in this respect all the English opticians; his rare skill and nice manipulation enabled him to perform wonderful feats in this direction, far in advance of anything before accomplished. Mr. Robert B. Tolles, for some time connected with Spencer, but now by himself at Boston, has devoted himself to the perfection of the achromatic objectives with enthusiastic zeal and unparalleled success. His recent objectives are quite equal in defining and penetrating power to the very best of the London opticians, both with central and oblique illumination, and greatly superior to them in the latter case, as regards chromatic aberration; this is true also of Mr. Spencer’s objectives. Mr. Tolles’s objectives range from 3 in. to \( \frac{1}{2} \) inch; the latter objective is a marvel of optical art. Messrs. J. and W. Grunow of New York have sent out some very fine objectives, ranging from 2 in. to \( \frac{1}{2} \) in. They have not attempted generally so high angles as Spencer and Tolles, but have devoted great attention to the mechanical arrangement and efficiency of their stands, and the accessory apparatus. Mr. William Wales came to this country in 1863, and settled at Fort Lee, N. J. His objectives are known the world over for their excellence; and among Tolles, Wales, and Powell and Lealand it is now impossible to assign any superiority in the performance of their lenses. The superior workmanship and elegant form of the stands made by Mr. Joseph Zentmayer of Philadelphia are perhaps not equalled, certainly not surpassed, by the production of any other maker. (See fig. 2.) Among other improvements given by this artist to the working microscope we would specially mention the remarkably thin and steady stage of his “grand American microscope,” his invaluable glass stage, and his mechanical finger for picking up and arranging diatoms. The latter invention, described in the “American Journal of Science” for May, 1870, is an improvement on the invention of the distinguished American microscopist Prof. H. L. Smith, described in the same journal for May, 1866. Of English opticians, the name of Andrew Ross has always been placed foremost, being connected with the greatest improvement of the objective, without which the higher powers of large angle would be almost valueless; we allude to the adjustment for cover. First of all the
the American and English opticians, and more recently by the French and German. The English uniformly, if we except the amateur efforts of Mr. Wenham, make the front set immovable; the American opticians generally move the two posterior sets, the front being immovable; the latter method is better, the object being kept easier in view during the adjustment, and there being no danger of bringing the front lens in contact with the object. The objectives of Mr. Ross have always maintained a high character, and have been more expensive than those of Powell and Lealand, or Smith, Beck, and Beck, though they probably do not surpass them. The business is now conducted by Mr. Thomas Ross and Mr. Wenham. Mr. Ross’s objectives range from 3 in. to \( \frac{1}{3} \) inch. Messrs. Powell and Lealand, so far as the objectives and accessories are concerned, are quite equal to any living opticians. Both the low and high powers of this firm are of the finest character. While the general plan is the same, there are some peculiarities in their high power objectives worthy of notice. The front set is triple, and the front lens, being of crown glass, is less liable to injury from wiping, or accidental contact with the object, than the soft flint of other opticians; but as it is a very thin plano-convex, merely cemented to the concave, and not burnished in, it is liable to injury by parting the cement. Messrs. Smith, Beck, and Beck (now R. and J. Beck) are more widely known in this country than the other firms. Their “students” and “educational microscopes” are the forms usually sold by the dealers. As opticians, for the lower power objectives, they stand side by side with the others named. They did not until lately furnish objectives higher than \( \frac{1}{3} \) of 125° angle. We can only mention the names of Nachet, Oberhauer, and Kellner, whose objectives are excellent, but inferior to the American or English; they are, however, much cheaper, and the mechanical work upon their instruments is very excellent. The name of Prof. Amici of Modena was long associated with the microscope. The objectives made by him consisted of six series, with angles varying from 36° to 160°; the higher powers had no adjustment for cover, but the front lens was slightly concave, and a drop of water introduced between the cover and the objective, thus in a measure rendering the adjustment unnecessary. The marked advantage in the plan of Prof. Amici, of introducing a stratum of water between the front lens of the objective lens and the thin glass covering the object, was fully shown by its originator 12 or 14 years ago; but it was only after Nachet of Paris adopted the idea and thereby greatly improved the working of his objectives, that opticians viewed Amici’s principle with favor. E. F. Hartnack of Paris, the successor of Oberhauer, at once adopted the “immersion” system, as it is called, and soon came to the very front of all objective makers. The advantage of this system is well stated by Harting: “As the water is a stronger light-refracting medium than air, the reflection of the rays of light is much diminished at the under surface of the objective; indeed it almost entirely ceases. Hence more rays of light pass into the microscope, and the thin stratum of water has nearly the same effect as an enlargement of the angle of aperture. This favorable modification influences chiefly the peripheral rays, which fall most obliquely. The peripheral rays have most influence on the formation of the image, which takes place in front of the eye piece; and as, by their passing through a transparent object, they are for the most part deflected from their course, and the slight deviations thus caused become visible in the image, the defining power of the microscope must necessarily be increased by the stratum of water.” The magnifying power as well as the angle of aperture is increased by the stratum of water in which the objective is immersed, for the water acts like the cover glass, and the lenses must approach each other in proportion to its thickness. The advantage of an immersion lens over the ordinary dry objectives cannot be better shown than by the following experience of Dr. J. J. Woodward, United States army. He had three superior lenses, all made by Powell and Lealand: a \( \frac{1}{3} \) and a \( \frac{1}{2} \) dry lenses, and a \( \frac{1}{4} \) immersion lens. The former lenses could resolve only the 15th band on Nobert’s 19-band test plate, but the \( \frac{1}{3} \) immersion lens not only resolved into lines this 15th band, but also the 16th, 17th, 18th, and 19th bands. Finally, we must not omit to name Mr. Lister, who first pointed out the peculiarities possessed by a combination of three achromatics with their plane sides toward the object, the crown and flint being cemented together, and which were the basis of subsequent improvements. The peculiar form adopted by Lister has long since been abandoned; but the principles are the same.—The stands furnished by the principal makers exhibit a great variety of patterns, and combine various excellences. The most desirable points, viz., freedom from tremor, ease of illumination, particularly oblique illumination, facility in the application of the accessory apparatus, and delicacy of adjustment, are nearly equal in the first-class stands of the principal opticians; but perhaps, on the whole, the best are those of Mr. Zentmayer and of R. and J. Beck. Their large stands mounted on two pillars are remarkably steady. The stage, thin but substantial, is large, and its movements are very smooth and delicate. The illuminating and accessory means is carried by a sub-stage below, and most easily applied. The illuminating mirror is large, and so mounted as to give very oblique illumination. The rackwork of the quick adjustment is always of the smoothest and best character in all of the instruments made by these firms, and the slow adjustment very delicate. The greatest fault
in their stands is the attachment of the slow movement at the lower part of the tube of the microscope itself. In this respect the stands of Ross, Powell and Leeland, Spencer, Tolles, and the Messrs. Grunow are superior. With the high powers, the springing of the tube when the finger is applied, and the shaking when the adjustment for cover is attempted, are disagreeable. The larger students' microscope made by Beck is a very fine instrument; the stage movements and adjustments are very complete. The stands furnished by Ross are heavy and cumbersome; they are, however, exceedingly steady, and finished with extreme care. Those supplied by Powell and Leeland are much lighter, and have some peculiar advantages. The accessories supplied by this firm are more complete than those of any other; the stage of their new and largest instrument is very thin, and allows greater obliquity of illumination than that of Beck. Their achromatic condenser is beautifully finished; it has an angle of 17°. The stand itself is not as steady as that of Beck, but the fine adjustment is more conveniently placed. The stands furnished by Messrs. Grunow are of different patterns, but all excellent in beauty of finish, smoothness of adjustment, and steadiness, comparing most favorably with the English work. The stands furnished by Spencer and Tolles have many excellences, and are very steady. —All good instruments should have a graduated draw-tube within the main tube, and the latter should be not less than 1-4 inch in diameter. The draw-tube is absolutely necessary for micrometry, and is very convenient to receive the analyzing prism, erector, or Tolles's amplifier. Two adjustments for focus are also necessary, one quick by rack-work and pinion, the other very delicate by screw. The pinion heads should be large, to allow of most delicate movement, and Messrs. Beck and Zentmayer graduate the head of the screw of the fine adjustment, so that the thickness of covering glass may be measured. A skilful observer may dispense with the rack movement, and produce the approximate adjustment by sliding the tube. This is the method adopted in most of the French instruments, and in the "educational" of Beck. The stage movements should be smooth, and but slightly disturb the adjustment when in focus. The adjustment for wear in the English instruments is by spring, in the American by screws; the former involves more work for the maker, but is better. The lever stage, though performing finely when first from the hands of the maker, is much more liable to derangement than that in which the motions are produced by rack and screw. In the Beck instruments the rack and screw are both so low that the latter passes entirely under the bottom of the stage, which is consequently much thinner than it can be made when the screw is introduced between the movable plates; the milled heads themselves are thus dropped below the level of the stage, and this is deemed of great importance; this is also the case with Powell and Leeland's large microscope.—One of the most important of recent improvements in the microscope has been the adaptation of the instrument to stereoscopic binocular vision. The binocular microscope, as we now have it, is the result of gradual progress in the application of Prof. Wheatstone's discovery of the stereoscope, from the year 1851, when Prof. Riddell of New Orleans first attempted the production of micro-stereoscopic relief, to the recent simple and universally used invention of Mr. Wenham. M. Nachet, Prof. H. L. Smith, Messrs. Powell and Leeland, Mr. Tolles, and Dr. Barnard have also devised special plans to obtain the same effects. Some of them have their own special advantages, but Mr. Wenham's recent invention is so simple that it has been almost universally adopted by American and English makers. We will therefore only describe here his invention, and refer the reader who desires information of the plans of the above named gentleman to Beade's "How to Work with the Microscope" (London, 1868); to Carpenter "On the Microscope" (London, 1868); and to the report of Dr. F. A. P. Barnard "On Machinery and Processes of the Industrial Arts, and Apparatus of Precision," exhibited at the Paris exposition of 1867. The pencil of rays which has passed through the objective is cut in half by the interposition of a trapezoidal prism $a$, as shown in fig. 3, $A$; half of the rays of the pencil pass up the tube as usual, and the other half enter the anterior face of the prism and are reflected from the lateral surfaces $b$ and $c$, and emerge at $d$ to
proceed up the secondary tube 2, as shown in fig. 8, B. To obtain stereoscopic effect it is absolutely necessary, on account of the crossing of the rays of the pencils in the objective, that those rays which have emanated from the right-hand half of the cut pencil should enter the left eye, and vice versa. If this does not take place, we shall have, instead of stereoscopic relief, a pseudoscopic effect; that is, elevations will appear as depressions and depressions as elevations. This was the case with Prof. Riddell's invention and with the first plan adopted by Mr. Wenham. In Mr. Wenham's recent invention, which we have just described, this is avoided by causing the rays reflected from the face e of the prism to cross those going directly up the tube, so that the right eye receives the left half of the pencil, and the left eye the right half. The distance between these best 1 and 2, fig. 8, A, is adapted to different eyes by means of racks and a pinion, by which they are moved inward or outward. There are two great advantages in using the binocular microscope: first, the eyes are subjected to equal work, and thereby are not so liable to fatigue and injury; secondly, with low powers we obtain an insight into the three dimensions of a body, for in the stereoscopic binocular we see into the depth of a body as well as view its length and breadth. This is very important in the study of tissues, as we see how they are arranged in order of distance from the surface of the body.—The usual accessories accompanying the microscope are: an achromatic condenser, a bull's-eye condenser, small condenser, stage and eye-piece micrometers, polarizing apparatus, camera lucida, animalcule cage, stage forceps, glass parabol, erector, Lieberkühns and dark wells, frog plate, &c. The name of achromatic condenser has been given to an illuminating apparatus consisting of an achromatic objective of large angle, furnished with a diaphragm, and central stops; when the latter are used, oblique illumination is obtained. This condenser is exceedingly useful in the ordinary studies by the microscope. With the proper adjustment it affords a fine achromatic illumination, revealing the structure of the object with great beauty and clearness; but in unskilful hands it will be of little service. So far as oblique illumination is concerned, we prefer unilateral light, though some particulars of strength may be arranged by aid of the achromatic condenser. The condenser is placed below the main stage, and can be adjusted by independent rackwork, so as to give the best illumination. The condenser of 170° angle, introduced by Powell and Lealand, is spoken of very highly by the English microscopists; the delicate markings of *narcicula rhomboidea*, when viewed with their *rr* objective, are said to be well defined as those of *pleuroslgma hippocampiforme*, viewed with a 4. The achromatic condenser of Beck has an angle of about 100°. When used with the central stops, the proper point for adjustment may be determined by removing the eye piece, after the objective has been brought into focus, looking down the tube, and moving the condenser by means of its own rack and pinion, until the black stop appears sharply defined in the centre of the field, and a bright illuminated ring around it. If the stop is removed, the whole field will appear brightly illuminated, unless the objective be of much greater angle than the condenser. A condenser of greater angle than 100° cannot be used unless the object be placed upon very thin glass; all difficult test objects should be mounted in this manner on a slip of mahogany, or on a perforated glass slide. The condenser itself, or the carrier, should have some means of adjustment to make its axis coincide with that of the objective; the front set of lenses is generally made to be removed, thus affording an illuminator of lower angle, to use with thicker glass and objectives of low power. In using the achromatic condenser by lamp light, the bull's-eye condenser is employed to render the rays parallel, and the plane side of the mirror is used. The bull's-eye condenser consists of a thick plano-convex lens, of short focus, mounted upon a stand so that it can be used for the illumination of opaque objects. Very excellent oblique illumination may be obtained by condensing the flame of a candle or lamp, placed about two feet from the stage, upon the under surface of the slide, the light being placed in front, and the stage slightly turned up to receive it; or, the microscope being placed horizontal, the light may be off at one side, according to the obliquity desired. As the thickness of the stage will not ordinarily allow illumination at a much greater distance than 60° from the axis, a sub-stage, attached to the upper plate of the main stage, but carrying the slide entirely below it, is furnished by Messrs. Gra-now and by Powell and Lealand, and may be readily attached to any microscope; this allows illumination of any obliquity. In using the bull's-eye condenser for this purpose with a lamp, the plane side must be presented toward the object; and if the flame be flat, its edge must be presented. The small condenser is used in the same way as the bull's-eye. Where very intense illumination is desired, the bull's-eye is placed near the source of illumination, with the plane side toward it, so as to render the rays nearly parallel, and then this beam of light is further condensed by the small condenser. An achromatic lenticular prism of short focus is very valuable for illumination. The prism should be so mounted that it can be placed to reflect converging rays on the object at any angle, and in any position, both below and above the stage. Experience in its use will to a great extent supply the need of an achromatic condenser.—The stage micrometer is a slip of glass ruled into '01' and '001' of an inch; it is used in conjunction with the camera lucida, or to determine the value of the
divisions of the eye-piece micrometer. The French scale is the millimètre divided into 100 or 200 parts. The eye-piece micrometer, known as Jackson's micrometer, is a finely ruled glass scale, introduced by means of an opening between the field and eye-lens of the eye piece, so as to be in the focus of the eye lens. The value of the scale is determined by placing the stage micrometer on the stage, and viewing the divisions with the given objective and eye piece; thus, if 10 divisions of the eye micrometer corresponded with one (0'1') of the stage micrometer, then the value of one division of the eye-piece micrometer would be '001' with that particular object glass and eye piece. The stage micrometer being replaced by any object, its dimensions may be readily ascertained by noticing how many divisions of the scale are subtended by it. The micrometers of this description are very convenient, and, when carefully used, accurate. The definition is slightly injured, however; this objection is obviated by Mr. Tolles's solid micrometer eye piece. If the observer has only a stage micrometer, the divisions may be projected on paper by means of the camera lucida; then, with the same objective and eye piece, the image of any object being projected on the paper, its dimensions are at once ascertained. Messrs. Powell and Lealand furnish a cobweb micrometer susceptible of great accuracy; it is similar to that used for astronomical purposes. Messrs. Grunow have somewhat improved upon Powell and Lealand, and their cobweb micrometer with orthoscopic eye piece is very delicate. They also furnish Fraunhofer's stage micrometer, which has the advantage of giving the absolute dimensions of the object, without reference to the power of the objective or eye piece. With careful use the eye-piece micrometer is as accurate as any of these, and much less expensive. —The polarizing apparatus consists of two Nicol's prisms of calc spar with revolving fittings, one (called the polarizer) designed to be placed below the object, the other (termed the analyzer) above, either directly over the eye piece, where it generally cuts off part of the field, or at the lower end of the draw-tube; here, if the prism be good and not too long, it will not much affect the definition, and will allow the whole field to be visible. Very much depends upon these prisms. Those supplied by the Messrs. Grunow are very large and fine, and the analyzer is placed by them directly above the objective; it is too large, however, to be placed so low down without injury to the definition. Beck's analyzer is much shorter than Grunow's, and may be used either over the eye piece or placed in the end of the draw-tube. There is much difference in these prisms; some scarcely injure the definition at all, and others are very poor. The polarizer is usually somewhat larger than the analyzer. The calc spar is very soft, and, if not protected by thin glass covers, liable to injury. A set of revolving selenites, to go below the object, between it and the polarizer, accompanies the prisms. There is not much choice in the method of mounting and revolving these prisms; perhaps Grunow's is the most elaborate, but, when the revolving selenites are included, we think Beck's arrangement the most complete. A "selenite stage" is often employed, simply placed under the object, on the stage of the microscope. Mr. Darker has contrived a stage of this kind, in which the selenites rotate. A complete polarizing apparatus is very important, and should be attached to every good instrument. Sometimes tourmalines are used instead of the prisms of calc spar; they are objectionable on account of their color, but placed over the eye piece do not at all obstruct the field of view. —The camera lucida furnishes the means of drawing or sketching outlines of objects viewed in the microscope, some provision for which is absolutely necessary. Often this is merely a plate of neutral tint glass, which, placed in front of the eye piece, at an angle of 45°, when the microscope is turned horizontal, reflects the image to the eye, and at the same time pencil and paper upon the table may be viewed through the glass. A better contrivance than this is the steel disk of Sömmerring, made slightly smaller than the pupil of the eye; this, when placed in front of the eye piece, enables one to view the object at the same time. In these contrivances, and also in the Nachat drawing prism, the object, being viewed after but one reflection, is reversed right and left. Where it is necessary to finish a drawing by the eye, this is a serious difficulty; it is therefore preferable in all cases to use the Wollaston prism, which is applied so as to give an unobstructed view of the whole field, and with which the drawing is precisely as it appears in the microscope without the prism. A little practice is required to use it well, but if the observer will take care to have the paper strongly illuminated, while the object is only enough illuminated to be seen distinctly, no great difficulty will be found. But whoever does much original work with the microscope should not depend on drawings made with the camera lucida, but should learn to photograph the objects he has discovered, or the histological preparations he has made. The eminently successful work of Drs. Edward Curtis and J. J. Woodward, at the army medical museum in Washington, should encourage all who have the means to adopt this accurate method of permanently securing the results of their labors. —The animalcule cage is a simple contrivance by means of which a drop of water may be retained between two glass plates, which may be approximated so as to just confine the object, without allowing, if it be living, too much freedom of movement; it is often made to serve the purpose of a compressor, for crushing soft bodies more or less during the examination. —The stage forceps is exceedingly useful for the examination of small insects. At one end is usually placed a bit of
cork, enclosed in a brass cylinder pierced with holes, to receive an insect pin, in case it be desirable to examine cabinet specimens. The forceps should have free movement in all directions and distinct ones supplied by having a ball and socket movement; they are attached to the upper stage plate, and thus are moved by the rack and screw of the stage. — The parabola was originally contrived by Mr. Wren- ham, and was composed of a silver reflector; it is now made of glass, the outer surface having the form of a parabola. The rays of light, entering the glass through a plane surface below, suffer total reflection, and emerge without refraction, the upper surface of the truncated parabola being concave, so that each reflected ray strikes upon the surface perpendicularly. The glass parabola has a small hole in the axis, carrying a sliding rod, with a small disk, which may be elevated or depressed according to the angle of aperture of the objective, until the direct light is excluded; the object is then exhibited entirely by oblique light on a dark field. The *polycyathina* are beautifully shown by this illumination, and also parts of insects with the lower powers. — The erecting prism of the compound microscope, one should acquire the habit of keeping both eyes open. If the eyes are allowed to rest easy, and then the focus carefully adjusted to suit while resting, no great fatigue will be experienced in using the microscope; if, however, the focus is only approximated, and then distinct vision obtained by forcing the eye, severe pain and headache will ensue. The writer has worked with a bright light for six or eight hours, with but slight intermission, without fatigue. Long experience and great caution are requisite in interpreting the phenomena revealed by the microscope, and one soon learns that things are not always what they seem. This, however, cannot be justly urged against its use. When directed by skilful hands, and guided by experience, its revelations are of the most exalted and truthful character. No one can hope to succeed in the department of natural history who is not a skilful microscopist. A north light, coming from the left hand, the stage movements being at the right hand, is the best light for day. At night, the naphtha or coal oil lamp, as now made by Beck, gives the most intense and steady flame. The gas jet is difficult to manage for delicate work. — A simple and very effective arrangement for illumination is that used by Dr. Edward Curtis of New York: "A small petroleum lamp is placed in a cigar box, which stands on one of its ends. On one side of the box is cut a small aperture, in which is placed a piece of blue glass, to soften the light as it passes to the microscope mirror. Another larger opening is made in the front of the box, and is occupied by three different glasses. The one nearest the lamp is a square piece of ground glass; the next one is also square and flat, but colored blue. Finally, a plano-convex lens of long focus is placed at such an inclination as to condense the rays of light, thus softened, on to the work-table for use in dissecting or in arranging preparations." — Many of the "test objects" have been so long known that it seems almost unnecessary to mention them. The markings on the silicious shells of diatoms have been highly recommended. As general tests, they are no doubt very serviceable, but they are not en-
tirely to be relied upon unless the same specimen is used in comparisons, on the same stand, and with the same illumination. In the following tables the usual tests, both for direct and oblique illumination, are given:

<table>

J. D. Möller of Wedel, in Holstein, who is well known for his beautiful mountings, furnishes a plate on which are mounted, in a line, the following 20 diatoms, in the order designated by Dr. Grunow: 1. triceratium furus; 2. pinseudaria nobilis; 3. navicula lyra, var.; 4. navicula lyra; 5. pinseudaria interrupta, var.; 6. Staurodes phanericoten; 7. grammatophora marina (more coarsely marked than Bourgoynes variety); 8. pleurosigma balticum; 9. pleurosigma acuminatum; 10. Nitzschia amphigrya; 11. pleurosigma angulatum; 12. grammatophora oceanica subtilissima (marina); 13. suvirella gemma; 14. Nitzschia sigmoidea; 15. pleurosigma fasciolata, var.; 16. suvirella gemma (longitudinal lines and beads); 17. cymatopleura elliptica; 18. navicula grossneri, frustulita Sazonica; 19. Nitzschia eurelia; 20. amphipleura pellicula. Dr. Woodward has photographed suvirella gemma, and has obtained the longitudinal striae as rows of minute hemispherical bosses. The fine transversal striae counted longitudinally are at the rate of 72 to the \( \frac{1}{100} \) of an inch. Transversely these lines were resolved into beaded appearances, which counted laterally 64 to the \( \frac{1}{100} \) of an inch.” ("American Journal of Science, May, 1871.") But all organic markings are variable as to dimensions and visibility, and hence are not comparable except when one and the same object is used in the comparison of the efficiency of two lenses. Mr. Nobert has succeeded in giving comparable test objects to microscopists by ruling on glass plates bands of parallel lines, the distances between the lines of successive bands constantly decreasing. His most recent plate contains 19 bands. The distance between the lines in the first band is \( \frac{1}{50} \) of a Paris line, and increases by \( \frac{1}{50} \) in each to the 19th, in which it is \( \frac{1}{50} \). The lines in the higher orders of bands are as close together as those of the diatoms whose markings are difficult to resolve. M. Schultz resolved the 15th band, and subsequently Dr. H. Fayah resolved the 17th, with a Hartnack immersion No. 11. In 1869 Dr. Woodward resolved the 18th and 19th bands with an immersion \( \frac{1}{50} \) of Powell and Lealand, and Dr. Edward Curtis photographed them. Dr. Woodward says ("American Journal of Science," September, 1869): "The photograph of Dr. Curtis was taken without an eye piece and with such a distance that the impression gave 1,000 diameters. The illumination was by sunlight passed through the ammonio-sulphate of copper, a \( \frac{1}{50} \) objective of 145° angle of aperture being used as the condenser, without diaphragm or stop, and obliquity of light obtained by means of the centring screws of the secondary stage. . . . Returning now to this immersion \( \frac{1}{50} \), it may be remarked that the work just done with it has an important bearing on the question of the real limits of microscopic vision. Nobert, in sending me the plate above described, was aware that in his opinion the 15th band was the limit of possible microscopic vision. He based his opinion upon Fraunhofer's formula with regard to the spectra of gratings, and upon the known wave length of light undulations. Dr. Barnard of Columbia College, New York, after reading Nobert's letter, writes me that in his opinion Fraunhofer's formula does not apply to the visibility of fine lines when observed with a modern microscope of high power, since the great angle of aperture of the objective permits oblique rays to reach the eye, and Fraunhofer's formula applies only when the eye is perpendicular to the grating. Dr. Barnard is therefore of the opinion that the limit suggested by Nobert has no real existence. In his letter, which I should mention was written before he was aware that I had satisfactorily resolved any of the bands beyond the 15th, he proposed that a trial should be made, to resolve the test plate with monochromatic light, of colors longer than the violet which I had been using. Accordingly, obtaining monochromatic light by a prism on which a ray of sunlight was thrown, I succeeded after some trials in satisfactorily resolving the 19th.
band with each of the colors of the spectrum, from the violet to the red. It may therefore be concluded that the present limit to microscopic vision is simply the goodness of the objective; and the rapidity of recent improvements may well lead us to hope for a still further advance." Subsequently Nobert ruled, for the scrutiny of Drs. Barnard and Woodward, lines approximated even closer than the 19th band, but the test has exceeded as yet the resolving power of their lenses. In judging of the merits of an objective, it appears to us that oblique illumination has had too much dwelt upon. The angle of aperture having been ascertained, the general merits will be much more apparent by use of tests, Nobert's lines for example, with the best central illumination. If the scale of podura plumbea is employed, select a medium-sized rather than a large one. The wedge-shaped dots should be sharply defined, without fog or mist. The scales of the American podura are not dotted but lined, and are not so suitable.—C. Quckett "On the Use of the Microscope" (London, 1848; last ed., 1865); Robin, Du microscope (Paris, 1849); Harting, Het Mikroskoop (Utrecht, 1862; translated into German by Dr. Theile, Brunswick, 1859); Wynthe, "The Microscopist" (Philadelphia, 1853); Schacht, "The Microscope," edited by Currey (London, 1855); Griffith and Henfrey, "Micrographic Dictionary: Introduction" (London, 1856); Gosse, "Evenings at the Microscope" (London and New York, 1859); West, "Half Hours at the Microscope" (London, 1859); Beale, "Application of the Microscope to Clinical Medicine" (2d ed., London, 1859); Clarke, "Objects for the Microscope" (London, 1859); Hogg, "The Microscope" (London, 1867); Beale, "How to work with the Microscope" (London, 1868); Carpenter, "On the Microscope, its Revelations, and its Uses" (London and Philadelphia, 1869); Woodward, "Photo-micrography," in the "American Journal of Science," vols. xii. and 1.; F. (New York, 1872); "Transactions of the Microscopical Society of London;" and "Quarterly Journal of Microscopical Science" (London).

MICROSCOPIC ANIMALS. See ANIMALCULES. MICROSTHENES. See MEGASTHENES. MIDAS, the name of several mythical kings of Phrygia. Rawlinson remarks in a note to Herodotus: "In the royal house of Phrygia, the names Midas and Gordius seem to have alternated perpetually, as in that of Cyrene the names Battus and Arceolans. Every Phrygian king mentioned in ancient history is either Midas, son of Gordius, or Gordius, son of Midas. Bouhier reckons four kings of Phrygia named Midas, each the son of a Gordion. Three of these are mentioned in Herodotus." Duncker, in Geschichte des Alterthums (4th ed., Leipsic, 1874), places the reign of the first Midas in the middle of the 8th century B.C., and supposes the dynasty to have become extinct in the 6th, with the successors of the third Midas, King Gordius and his son Adrastus. The following is the principal myth connected with the name of Midas. Midas conferred a favor on Bacchus, and the god desired him to ask whatsoever he pleased. Midas requested that everything touched by him might become gold. The request was granted, but as his food underwent the metamorphosis as well as all things else, he was reduced to a state of starvation, and implored the god to recall his grant. Bacchus bade him bathe in the Pactolus; and Midas having done so, instantly his touch lost its auriferous power in the case of all things essential to life, while the sands of the river were converted into gold. Midas was once chosen umpire in a musical contest between Pan and Apollo; he awarded the palm to Pan, in revenge for which Apollo changed his ears into those of an ass. Midas to hide this deformity, used to wear a lobed cap; but the slave whose business it was to cut his hair became privy to the secret, which so troubled him that, to afford him to a fellow mortal, and unable to keep it to himself, he dug a hole in the earth, and whispered into it: "King Midas has asses' ears." He then filled up the hole, but a reed sprung up on the spot, which, as often as the wind blew, whispered his words to the world. Midas is said to have killed himself by drinking the blood of an ox.

MIDDENBURG, a town of Holland, capital of the province of Zeeland, situated near the centre of the island of Walcheren, 82 m. S. W. of Amsterdam; pop. in 1871, 16,580. The town is circular, and surrounded by a ditch and a bastioned mound, the top of which forms a favorite public promenade. It has a gymnasium, an academy of design, a clinical school, a theatre, and various manufactures. The town hall was built by Charles the Bold in 1485, and is ornamented with 25 colossal statues of counts and countesses of Flanders. The town was founded in 1132, belonged for some time to the Hansa, and was taken by the Dutch from the Spaniards in 1574. The British lost 7,000 men here from the effects of the climate during the famous Walcheren expedition in 1809.

MIDDLE AGES. See Ages.

MIDDLETOWN, a town and the capital of Addison co., Vermont, on Otter creek at Middlebury falls, and on the Rutland division of the Central Vermont railroad, 35 m. S. of Burlington, and 33 m. S. W. of Montpelier; pop. in 1870, 8,080. It is surrounded by attractive mountain scenery. Fine white and variegated marble is found here, and large quantities are quarried and exported. The town contains a cotton factory, a woollen factory, an iron foundery, a national bank, a weekly newspaper, 14 public schools, including a high school, and five churches. It is the seat of Middle-
bury college, under the control of the Congregationalists, opened in 1800. It occupies three large buildings, and in 1873–4 had 8 professors, 52 students, a cabinet of zoology, botany, and mineralogy, and a library of 11,000 volumes.

**MIDDLESBOROUGH**, a town of Yorkshire, England, in the North riding, on the Tees, 34 m. from its mouth and 29 m. S. S. E. of Newcastle-on-Tyne; pop. in 1871, 39,585. The population of the township in 1821 was only 40; in 1831, 154; in 1841, 4,500; in 1851, 7,431. The rapid increase is attributable to the rise of the coal trade, consequent on the opening of the Stockton and Darlington railway, from the collieries of south Durham. The town was regularly and substantially built by a joint-stock company, as a port for loading colliers. In 1878 it had 21 places of worship. There is also a national school, and an observatory. The number of vessels entering the port in 1871 was 1,278, tonnage 247,937; cleared 1,407, tonnage 268,952. There are important manufactories of sail cloth and rope, an extensive pottery, iron works, and ship yards.

**MIDDLESEX.** 1. A N. E. county of Massachusetts, bordering on New Hampshire, bounded S. E. by the Charles river and drained by the Merrimack, Nashua, and Concord rivers, and other streams; area, 888 sq. m.; pop. in 1870, 274,933. The immense water power supplied by a number of streams is largely employed in manufactures. Several railroads intersect the county. The chief productions in 1870 were 20,350 bushels of rye, 190,965 of Indian corn, 56,302 of oats, 14,580 of barley, 443,090 of potatoes, 520,136 lbs. of butter, and 74,678 tons of hay. There were on farms 5,836 horses, 16,887 milch cows, 2,107 working oxen, 7,260 other cattle, 983 sheep, and 8,104 swine. The total number of manufacturing establishments was 1,878, employing $43,528,466 capital, and having an annual product of $115,147,270. The chief establishments were 7 for bleaching and dyeing, 40 paper, 12 chemical, 3 glass, 15,967 of oats, 428,848 of Indian corn, 271,353 of oats, 246,830 of Irish and 12,391 of sweet potatoes, 418,434 lbs. of butter, and 37,160 tons of hay. There were 4,888 horses, 6,135 milch cows, 3,728 other cattle, 3,449 sheep, and 6,453 swine; 32 manufactories of brick, 1 of freight and passenger cars, 1 of drugs and chemicals, 3 of India-rubber and elastic goods, 2 of iron castings, 1 of paper hangings, 3 of sash, doors, and blinds, 2 of stone and earthen ware, 12 flour mills, 4 saw mills, 5 tanneries, 8 distilleries, 4 ship yards, and 1 cork-cutting establishment. Capital, New Brunswick.

2. A county of Canada, near the 39th parallel, bordering on Chesapeake bay, at the mouth of the Rappahannock river, which forms its N. E. boundary, and bounded S. W. by the Pianek-tank river; area, 170 sq. m.; pop. in 1870, 4,981, of whom 2,552 were colored. The chief productions in 1870 were 19,650 bushels of wheat, 86,967 of Indian corn, 11,429 of oats, and 13,754 lbs. of butter. There were 426 horses, 777 milch cows, 1,189 other cattle, 1,269 sheep, and 2,810 swine. Capital, Saluda.

**MIDDLESEX**, a S. W. county of Ontario, Canada, watered by the Thames, Aux Sables, and Sydenham rivers; area, 1,282 sq. m.; pop. in 1871, 82,595, of whom 58,464 were of English, 26,569 of Irish, 20,854 of Scotch, 2,888 of German, and 1,075 of Dutch origin, and 1,278 were Indians. It is traversed by the Grand Trunk, the Great Western, and the London and Port Stanley railroads. Capital, London.

**MIDDLESEX,** a S. E. county of England, bordering on Hertfordshire, Essex, Kent, Surrey, and Buckinghamshire; area, 283 sq. m.;
pop. in 1871, 2,598,882. It is the smallest county in the kingdom except Rutland, but the greatest in population. Much of its land is devoted to market gardening, though more of it is in meadow and pasture. The chief towns, besides London, are Brentford, the capital, Hounslow, and Uxbridge.

MIDDLETHIBET. See Ladakh.

MIDDLETON, the name of a family noted in the history of South Carolina. I. Edward, its founder, was a native of Twickenham, England, where he inherited a large property. He removed to South Carolina, and was a member of the council under the lords proprietors in 1680, 10 years after its settlement. He evinced decided republican tendencies, and maintained popular rights in opposition to the government. II. Arthur, son of the preceding, was a member of the council in 1712. His influence was exerted in favor of popular claims, opposing the close borough system of the lords proprietors, and finally he headed the revolution which threw off the proprietary government and placed the colony under the immediate protection of the crown (1719). He was governor of the colony from 1725 to 1731, after which he remained in the royal council.

III. Henry, son of the preceding, was an aged man at the outbreak of the revolution, but was sent as a delegate from South Carolina to congress, of which body he was president in 1775. IV. Arthur, son of the preceding, born at the family seat on Ashley river in 1748, died Jan. 1, 1787. He was educated at Harrow and Westminster schools, and the university of Cambridge, and became a revolutionary leader. He was one of the most efficient members of the first council of safety. In 1776 he was sent as a delegate of the state to congress, and as such affixed his signature to the Declaration of Independence. He held his seat in congress till 1777, declined the governorship of South Carolina in 1778, took the field for the defence of Charleston in 1779, saw his plantation devastated by the British, was made a prisoner after the fall of Charleston in 1780, and was one of the leading citizens who were confined as hostages. His estate was sequestered, and he was confined in the castle of St. Augustine, and afterward in the Jersey prison ship. Exchanged in the latter part of 1780, he served till the close of the war as a delegate in congress, and was afterward elected to the state senate. He was a stenographer, and took down many of the debates in which he participated. He wrote effective political essays under the signature of "Andrew Marvell."

V. Henry, son of the preceding, born in 1771, died in Charleston, June 14, 1846. He was a member of the state legislature from 1801 to 1810; was governor of the state in 1810-12; a representative in congress from 1815 to 1819; and in 1820 was appointed minister to Russia, which post he held till 1831.

MIDDLETON, Couys, an English clergyman, born in Richmond, Yorkshire, Dec. 27, 1683, died at Hildersham, Cambridgeshire, July 28, 1750. He graduated at Trinity college, Cambridge, in 1702, was ordained deacon, was elected a fellow of his college in 1706, and in 1708 signed the petition against Bentley, the master. This was the beginning of a controversy between them, long continued in the university and in the courts, Middleton being twice convicted of libel. The office of principal librarian of the university was created for him. In 1726 Middleton published an attack upon the medical profession, entitled De Medicorum apud Veteres Romanos evidentiarum, entitatum et revocandam. In 1729 appeared his "Letter from Rome" (which he had visited in 1724), in which he attempted to show that "the religion of the present Romans was derived from their heathen ancestors." He also attacked the miracles of the Roman Catholic church in a way which awakened a suspicion of his disbelief in the miracles of the New Testament. A letter to Dr. Waterland published in 1731 gave still more serious offence to the clergy, and Middleton found it necessary to publicly avow his belief in Christianity. In 1735 he published "A Dissertation concerning the Origin of Printing in England," and in 1741 his most popular work, "The History of the Life of M. Tullius Cicero" (2 vols., London), from the profits of which he purchased a small estate at Hildersham, 6 m. from Cambridge, where he passed the rest of his days. The "History" was followed by a translation of the correspondence of Cicero and Brutus, together with a defence of its authenticity (1748), and a "Free Inquiry into the Miraculous Powers which are supposed to have subsisted in the Christian Church from the Earliest Ages" (1749), which exposed him again to the charge of infidelity. In 1750 appeared his "Examination of the Bishop of London's [D. Sherlock's] Discourses concerning the Use and Intent of Prophecy." His works, with the exception of the "Life of Cicero," were collected and published in 1762, in 4 vols, 4to, and subsequently in 5 vols. 8vo.

MIDDLETON, Thomas, an English dramatist, born in the latter part of the 16th century, died in July, 1627. In 1620 he was appointed chronicler or city poet of London. He was associated with Jonson, Fletcher, Massinger, and Rowley in the composition of several plays. "A Mad World, my Masters," "The Mayor of Queenborough," and "The Roaring Girl," are in Dodsley's collection. His "Game at Chess," performed in 1624, gave umbrage to the court on account of its allusions to the king and ambassador of Spain, and Middleton and the players were brought before the privy council and censured for their audacity in "bringing modern Christian kings upon the stage." From his play called "The Witch," Shakespeare has been supposed to have borrowed the witch incantations in "Macbeth."
MIDDLETON, Thomas Fushave, an English scholar, born at Kedleston, Derbyshire, Jan. 26, 1769, died in Calcutta, July 8, 1822. He was educated at Christ's hospital, London, and Pembroke hall, Cambridge, took orders, and while curate of Gainsborough in 1792 he edited a periodical called the "Country Spectator." His principal work is "The Doctrine of the Greek Article applied to the Criticism and Illustration of the New Testament" (London, 1808). He was prebendary of Lincoln in 1809, archdeacon of Huntingdon in 1812, and consecrated as first bishop of Calcutta, May 8, 1814. His sermons, charges, and tracts were collected and published with a life by Dr. Henry Kaye Bonney (London, 1824), and his life was also written by the Rev. Charles Webb Le Bas (2 vols. 8vo, London, 1830).

MIDDLETOWN, a city, port of entry, and one of the shire towns of Middlesex co., Connecticut, on the right bank of the Connecticut river, 30 m. above its mouth, 24 m. N. E. of New Haven, and 15 m. S. of Hartford; pop. of the city in 1870, 6,923, exclusive of 4,203 in the town. It is situated at the intersection of a branch of the New York, New Haven, and Hartford railroad with the Connecticut valley and the New Haven, Middletown, and Willimantic lines. The city has a gradual ascent from the river, with which the principal streets run parallel, crossed at right angles by others; it is well built, chiefly of brick, and has many fine situations and elegant mansions in the environs. It has a custom house built of Portland freestone, and a court house. The wharves have 10 ft. of water, and can accommodate such vessels as can cross the bar. During the year ending June 30, 1873, there were 229 entries, 5,071 bbls., and 665 tons, tonnage 720, all coastwise. There were belonging in the district 115 sailing vessels of 11,008 tons, 25 steamers of 5,815 tons, and 7 barges of 1,234 tons. There are four national banks, with an aggregate capital of $969,300, two savings banks with more than $8,000,000 of deposits, and important manufactures, embracing cottons, foundery products, britannia ware, hardware, silver-plated ware, rules, chisels, sewing machines, pumps, webbing, tape, guns, screws, leather, &c. The city has a daily and two weekly newspapers, and a bi-weekly, a high school and six other public schools, and 15 churches. It is the seat of the insane asylum, the state industrial school for girls, Wesleyan university (see WESLEYAN UNIVERSITY), and Berkeley divinity school (Episcopalian). The last named institution was established in 1854, and in 1873—4 had 5 professors, 34 students, and a library of 14,000 volumes.

MIDDLETOWN, a village of Orange co., New York, at the intersection of the Erie, the New York and Oswego Midland, and the New Jersey Midland railroads, 21 m. W. by S. of Newburgh, and 53 m. N. W. of New York; pop. in 1870, 6,049. It is in the midst of a wide undulating plain, partly between and partly upon several gradually sloping hills. The view to the north and south is unbroken, while on the west it is bounded by the Shawangunk mountains and on the east by the Highlands along the Hudson and the mountains beyond. In the S. W. part of the village is Hillside cemetery, containing 50 acres, handsomely laid out and adorned. The streets are broad, clean, well shaded, sewered, lighted with gas, and bordered with flagged sidewalks. Water is supplied from a reservoir of 80 acres, 2 m. from the village, elevated from 100 to 200 ft. above its level. It has a fire department, a police force, and a board of health. There are many substantial business blocks, a fine masonic hall, neat cottages, and handsome residences. The state homoeopathic asylum for the insane occupies a building capable of accommodating from 80 to 100 patients, with a wing in course of construction (1874) designed to accommodate 175 more. Middletown is surrounded by a rich dairy and stock-raising district, from which it derives a large and profitable trade. It has manufactories of saws, files, hats, furnaces, carpet bags, agricultural implements, lawn mowers, gloves, blankets, patent medicines, flavoring extracts, &c. There are several hotels, an opera house seating 1,000 persons, public halls, two national banks, a savings bank, five brick school houses with a system of graded schools, a female seminary, several private schools, a library and reading room, a daily and three weekly newspapers, and nine churches.

MIDGE, a small fly. See DIPTERA.

MIDIANITES, a nomad or half-nomad people of northern Arabia, who in the time of the early history of the Hebrews dwelt in the vicinity of the Arabian gulf and Dead sea, especially between Mt. Sinai and Moab. They are derived in Scripture from Midian, the son of Abraham by Keturah, and appear occasionally as merchants, and more frequently, like Bedouins, making raids into the neighboring territories of the Hebrews. Moses, who was himself the son-in-law of a Midianite priest, Jethro, waged a war of extermination against those of their tribes who in conjunction with the Moabites had enticed the Hebrews to idolatry when they were approaching Canaan. Gideon seems to have broken their power by his great victory over them and their allies the Amalekites. Some critics, to remove difficulties arising from apparently contradictory Scriptural statements, distinguish between Abrahamic and Cushite tribes of the same name, the former of whom, descendants of the same Semitic stock, lived in hostility to the Hebrews, while the daughter of Jethro is identified with the Cushite wife of Moses, mentioned in another part of his history (Num. xii. 1).

MIDLAND, an E. central county of the southern peninsula of Michigan, intersected by Tittibawassee river and drained by its branches, the Chippewa, Salt, and Pine rivers; area, 550 sq. m.; pop. in 1870, 3,285. The surface is
level and the soil fertile. The Flint and Père Marquette railroad passes through it. The chief productions in 1870 were 3,640 bushels of wheat, 6,838 of rye, 11,524 of oats, 23,408 of potatoes, 31,175 lbs. of butter, and 2,498 tons of hay. There were 257 horses, 315 milch cows, 409 other cattle, 298 sheep, and 254 swine. Capital, Midland.

MIDLOTHIAN. See Edinburghshire.

MIDSHIPMAN. The lowest grade of officers in the line of promotion in the naval service. The number of midshipmen in the United States navy in 1874 was about 100, and no one can be appointed unless he is a graduate of the naval academy at Annapolis. The members of this institution are denominated "cadet midshipmen," and the appointments are distributed by law among the states and territories which have not their relative proportion on the navy list; and it is further required that the appointments from each state shall be apportioned as nearly as practicable equally among the several congressional districts therein; that the person appointed shall be an actual resident of the congressional district from which he is appointed, and be recommended by the member of congress for that district. Since the revival of the apprentice system in 1864, 10 apprentices from the school ships are annually eligible by competitive examination to appointments in the naval academy, and of late several of the congressional appointments have been made from the apprentices. Candidates must be over 15 and under 18 years of age at the time of the examination for admission; must be free from deformity, disease, or imperfection of the senses; must be of good moral character, able to read and write well, writing from dictation and spelling with correctness, and to perform with accuracy the various operations of the ground rules of arithmetic. The examinations to which they are subjected are, first, by a board of three surgeons, and then by one of professors. If found qualified, they become members of the institution, their usual traveling expenses from their place of residence to the institution are paid by the government, and they are placed upon a pay of $500 per annum. The course of instruction at the naval academy, which now embraces a period of six years, includes mathematics, astronomy, navigation and surveying, ethics and English studies, natural and experimental philosophy, French and Spanish, drawing, artillery and infantry tactics, practical seamanship, naval gunnery both theoretical and practical, the steam engine, etc. During the academic course two cruises of about three months each are made in a ship of war for instruction. Warrants as midshipmen are conferred upon the graduates of the academy, who take rank in the order of merit. By the act of March 3, 1865, when on sea duty they receive pay at the rate of $800 a year. After two years of actual sea service, midshipmen, if they produce a favorable testimonial from their commands, are entitled to a final examination for promotion, which is made by a board composed of three captains and two commanders. This examination is on the practical branches of the profession, and includes seamanship and naval tactics, practical navigation, gunnery, and the steam engine. Having passed this, they receive new warrants as ensigns, with increased pay; and promotion to the higher grades of the service is open to them. In the British navy, young gentlemen intended for commissioned officers are educated, in the first instance, at the royal naval college; afterward, while serving at sea, and until their promotion to a higher grade than midshipman, they are obliged to devote a portion of their time to study under a competent instructor. They begin actual service as naval cadets, proceed as midshipman, and after 54 years of service, if they pass a proper examination in seamanship and navigation, and are 19 years of age, they are promoted to lieutenants. They are considered as the principal petty officers, rank comparatively with ensigns in the army, and their pay is £24 4s. a year. In smaller vessels some of the senior midshipmen are instructed with the watch; they take charge of boats and small parties of men going ashore, pass the word of command, and see that the orders of their superiors are carried into effect. A midshipman's share of prize money is the same as that of a petty officer, a cadet's equal to that of the captains of the tops; and both receive the rations of seamen, but may provide for themselves at their own expense. The French aspirants de marine perform similar duties to those of midshipmen. They are of two classes, are especially educated for their profession at the naval academy in Brest, and undergo a strict examination before receiving their appointment afloat, where they serve from the age of 12 to 20 years. They are not entitled to command a ship till they have attained the age of 21.

MIDWIFERY. See Obstetrics.

MIEL, or Miel, Jan, called by the Italians Giovanni della Villa, a Flemish artist, born near Antwerp in 1599, died in Turin in 1664. He was employed in decorating the Vatican, became a member of the Roman academy, and was appointed first painter to the court of Savoy. His easel pictures of fairs, carnivals, hunting parties, market scenes, gypsies, etc., are his best works. He etched several plates from his own designs. Some of his best pictures are in the imperial gallery in Vienna.

MIERS. J. Eras, the elder, a Dutch painter, born in 1635, died in Leyden in 1681. He was a pupil of Gerard Dou, and painted genre pictures and occasionally portraits, all remarkable for delicacy of finish, accuracy of drawing, and correctness of design. His pictures are not numerous, and bring very large sums. He died a prisoner for debt, on consequence of a devout course of life. H. Willem, son of the preceding, born in Leyden in 1602, died there, Jan. 24, 1747. He was the pupil of his
father, and equalled him perhaps in delicacy of finish, though he was inferior in color, drawing, and design. He attempted historical subjects in combination with landscape, and his picture of "Rinaldo asleep on the lap of Armida" was repeated by him in several copies. His domestic subjects are held in high estimation.

III. Frans, the younger, son of the preceding, born in Leyden, Dec. 24, 1689, died there, Oct. 22, 1763. He studied painting with his father, and executed similar subjects, although in a much inferior manner. He also made numerous copies of the works of his father and grandfather, which frequently pass for originals with inexperienced purchasers. He was an industrious student of history, and wrote several works relating to the Low Countries, including Historie der nederlande vorsten (3 vols. fol., the Hague, 1732–5), and Groot charterboek der graven van Holland, Zeeland en Vriesland (4 vols., Leipsic, 1753–6). He was engaged upon a history of Leyden at his death.

MIEKOSLAWSKI, Ludwik, a Polish revolutionist, born at Nemours, France, in 1814. He is the son of a Polish officer in the French service, and was educated at the military school in Kalisz. He joined the revolutionists in 1830, served with distinction in the campaigns of the following year, and after the fall of Warsaw removed to Paris. He published various books in Polish and French, and among others a critical military history of the Polish revolution. He was selected by the democratic organization of the Poles at Paris as principal leader for the next rising of Poland. This failed, however (1846), and Mieroslawski was arrested, tried at Berlin, and imprisoned under sentence of death. The Berlin revolution of March, 1848, opened his prison, and he immediately hastened to the duchy of Posen, and armed for another Polish rising. A bloody conflict was the result. The Poles gained a signal victory at Miloslau; but after some reverses Mieroslawski resigned his command, and the insurgents were disarmed (May). Early in 1849 he was summoned to Sicily to take command of the revolutionary forces; but after being wounded in the defence of Catania (March), he resigned his post. Once more he took command of a revolutionary army in Baden, but after a few encounters with the Prussians he was obliged to retire to the fortress of Rastadt, which surrendered soon after (July), and he returned to Paris. He took a brief part in the Polish insurrection of 1863, his command being disastrously defeated at Raziejewo on Feb. 22. He again returned to France, where he has since published several works on the political dissensions among the Polish emigrants.

MIFLIN, a central county of Pennsylvania, intersected by the Juniata river; area, 375 sq. m.; pop. in 1870, 17,508. It is traversed by several large mountain ranges; the chief subject for tile. The Pennsylvania canal and the Pennsylvania railroad, with its Lewistown division and Mifflin and Centre county branch, pass through it. The chief productions in 1870 were 322,385 bushels of wheat, 365,806 of Indian corn, 322,487 of oats, 73,211 of potatoes, 20,457 lbs. of wool, 415,115 of butter, and 15,005 tons of hay. There were 4,373 horses, 3,908 milch cows, 4,944 other cattle, 7,552 sheep, and 8,449 swine; 10 manufactories of clothing, 1 of edge tools and axes, 2 of pig iron, 3 of iron castings, 1 of engines and boilers, 9 of saddlery and harness, 4 of woolen goods, 6 flour mills, 4 saw mills, and 11 tanneries. Capital, Lewistown.

MIFLIN, Thomas, an American revolutionary general, born in Philadelphia in 1744, died in Lancaster, Pa., Jan. 20, 1800. He was by birth and education a Quaker, entered public life in 1772 as a representative from Philadelphia in the colonial assembly, and in 1774 was a delegate to the first continental congress. In June, 1775, he accompanied Washington to Cambridge as his first aide-de-camp, with the rank of colonel. Subsequently he was adjutant general, and in the spring of 1776 was commissioned as a brigadier general. He distinguished himself in the battle of Long Island, and in the latter part of 1776 raised considerable reinforcements in Pennsylvania for Washington's army. In 1777 he was made a major general, and became an active member of the "Conway cabal." The project of making Gates commander-in-chief failing, he resigned his commission, and in 1783 was elected to congress, of which he became president at the close of the year. In 1785 he was speaker of the Pennsylvania legislature, and in 1787 a member of the convention which framed the federal constitution. In October, 1788, he succeeded Franklin as president of the supreme executive council of Pennsylvania; and in 1790 he was chosen governor of Pennsylvania, which office he held till shortly before his death.

MIGNE, Jacques Paul, a French editor, born at Saint-Flour, Cantal, in 1800. He was ordained priest in 1824, and in 1833 founded in Paris the journal L'Univers religieux. This he sold in 1836, and conceived the design of publishing a collection in 2,000 volumes of the best ecclesiastical authors ancient and modern, at low prices, and to be called Bibliothèque du clergé. From 1840 to 1845 he issued simultaneously, in 28 volumes each, the Scriptura Sacra, Curser Completus and the Theologica Cursus Completus. He next founded at Petit Montarouge an immense establishment uniting all the branches connected with printing, and employing hundreds of workmen, besides a large staff of clergymen as assistant editors. From this were issued complete collections of the Latin and Greek church fathers, the medieval writers, modern controversialists, and pulpit orators. He also published Encyclopédie théologique (171 vols. 8vo, 1844—66), comprising three series of dictionaries on subjects connected with religion. Archbishop de Quèlen of Paris, deeming such an undertaking a mere commercial speculation, forbade the able Migne
to continue it, and as he did not comply withdrew his sacerdotal faculties. Migné also founded the daily independent journal La Vérité, which ceased in 1856, and reappeared as a weekly ecclesiastical record in 1861. In 1868 his immense establishment was burned.

MIGNET, François Auguste Marie, a French historian, born in Aix, May 8, 1796. He was educated at Avignon, and in 1818 was called to the bar. In 1820 he obtained a prize offered by the academy of Nîmes for an essay on Charles VII. The acquisition in 1821 of a more important prize proposed by the academy of inscriptions and belles-lettres, for a dissertation on the state of the government and legislation of France during the age of Louis IX., induced him to abandon law for literature, and he removed to Paris. His liberal political views recommended him to the editor of the Courrier Français, to the staff of which he was attached for more than ten years; and about the same time he began a course of historical lectures at the Athénée which gained him a considerable reputation. In 1824 appeared his first important publication, Histoire de la révolution française de 1789 à 1814 (2 vols. 8vo), frequently reprinted in France, and translated into the principal European languages. In 1830 he was associated with Thiers and Armand Carrel in the establishment of the National newspaper, and, having cooperated in the overthrow of the Bourbon dynasty, was appointed by Thiers upon his accession to office councillor of state and director of the archives in the ministry of foreign affairs. In 1832 he was elected a member of the academy of moral and political sciences, of which in 1837 he became the perpetual secretary; and in the same year he was admitted to the French academy. His political views were so distasteful to the government of Lamartine in 1848, that he was removed from his offices of director of the foreign archives and of councillor of state. Among his most important works are a series of books entitled Négociations relatives à la succession d'Espagne sous Louis XIV., with an introduction (4 vols. 8vo, Paris, 1836-42), constituting a complete history of the reign of Louis XIV.; Antonio Perez et Philippe II. (8vo, 1845); Vie de Franklin (1848); Histoire de Marie Stuart (2 vols. 8vo, 1851); and Charles Quint, son abdication, son séjour et sa mort au monastère de Yuste (1854). In 1843 he published several biographical papers under the title of Notices et mémoires historiques (2 vols. 8vo); and he has since published Éloges historiques (8vo, 1863). In December, 1874, he submitted to the academy his Notice historique de la vie et des œuvres du duc de Broglie, who died in 1870. For many years he has been engaged upon a history of the reformation.

MIGNONETTE (Fr. mignonnette, diminutive of mignonne, darling), the common name for Reseda odorata, a very popular garden annual. Though we derive our garden name as above indicated, the French use réseda as the common name. This genus and a few others form the small family resedaceae, which in a systematic arrangement occupies a place between crucifera and violaceae. The resedas are natives of Europe, northern Africa, and western Asia, and are herbaceous or somewhat shrubby plants, with alternate leaves, and greenish yellow or white flowers in long terminal spikes; the four- to seven-parted calyx is never closed, even in the bud; the petals as many as the calyx divisions, unequal, some or all deeply cleft or divided; stamens 10 to 40, borne on a glandular disk; ovary and pod of three to six carpels united, not quite to the top, to form a three- to six-lobed or three- to six-horned, one-celled pistil, which opens at the top long before the seeds are matured. The common mignonette (R. odorata) is much cultivated for the fragrance of its greenish white, inconspicuous flowers. In north Africa it is a perennial, but it is usually cultivated as an annual; the seeds are sown where the flowers are to bloom, and it springs up abundantly from self-sown seeds. For greenhouse culture, several seeds are sown in a pot and the plants thinned to three. What is called tree mignonette is only the ordinary kind which, by nipping off the flower buds, is prevented from blooming until it has formed a strong tree-like plant. By selection several improved strains have been produced. Mignonette is much used by florists to impart fragrance to bouquets of showy but inodorous flowers. The white mignonette (R. alba), with long spikes of odorless flowers, is rarely seen in gardens, and wild or dyer's mignonette (R. tuteola) is sparingly naturalized. (See WEED.)

MIGUEL, Dom Maria Evaristo, a Portuguese prince, born in Lisbon, Oct. 26, 1802, died at Brombach, Baden, Nov. 14, 1866. He was the third son of John VI. of Portugal and Carlotta Joachina, a daughter of Charles IV. of
Spain, and spent his early life with his parents in Brazil, returning with the royal family to Portugal in 1821. When his elder brother Dom Pedro became emperor of Brazil, and his father established a constitutional monarchy in Portugal (1822), Dom Miguel, instigated by his mother, and aided by several of the nobility and clergy and by a large part of the troops, formed plots against the new constitution. He rebelled in 1823, and in 1824, with his mother, was expelled from the country. He went first to Paris, and then to Vienna. His father died on March 10, 1826, and his sister Isabella Maria was for a short time regent of Portugal. Dom Pedro relinquished the throne of Portugal (May 2) to his daughter, Dona Maria (afterward Dona Maria II, da Gloria), then in her seventh year, offering her hand in marriage to her uncle Dom Miguel, who was appointed to the regency July 3, 1827, and took the oath to maintain the constitution (Feb. 26, 1829). Soon afterward he defeated the garrisons of Oporto and other places which declared for Dom Pedro, convened new cortes, imprisoned or exiled the legislators who were likely to oppose him, and was proclaimed absolute king on June 25. He consolidated his power by the most despotic methods. Those implicated in the Oporto insurrection were mercilessly punished, and the prisons of the country filled with liberals; an expedition was sent against Madeira and the Azores, whose inhabitants had refused to acknowledge him, and the islands were subdued with the exception of Terceira in the Azores. Dom Miguel's cruel administration soon became odious to the people. Terceira continued to hold out against him, and the leaders of the constitutional party gathered there, established a regency in the name of Dona Maria, and collected a fleet and army with which Dom Pedro, who had abdicated the throne of Brazil (1831), sailed in June, 1832, for Oporto, which he took without bloodshed. In the following year his fleet, commanded by Sir Charles John Napier, destroyed that of Dom Miguel, and the army advanced to Lisbon, which declared unanimously for Dona Maria. Dom Miguel was abandoned by most of his followers, and in May, 1834, concluded at Evora a convention by which he agreed to quit Portugal. He went to Genoa and to Rome, and subsequently spent several years in London, where he was noted for debauchery. In 1851 he married the German princess Adelheid von Lœwenstein-Wertheim-Rosenberg, by whom he had a son (Miguel, born in 1853) and four daughters.

MIKADO, a term of doubtful etymology, used to designate the emperor of Japan. The word does not occur in the most ancient Japanese books, but is the one, out of many names given to the emperor, which has obtained the greatest currency. The derivation of mikado usually accepted by the Japanese is from mi, honorable, august, and kado, a gate, equivalent to the Turkish title Sublime Porte. Another derivation, given by Satow, is from maka, grand, awful, and to, place. It originally meant the palace of the sovereign, but by a figure of speech especially common in Japanese, it is used for the sovereign himself, just as dairi, the palace, with the suffix sama, is also used. Other terms applied to the emperor are kotei, judge of the world, or ruler over nations; tenshi, son of heaven; kinri, the forbidden interior; dairi, the inner interior; chotei, hall of audience; and tenno, heaven-king. Tenno is the official designation now used, and all Japanese ministers and consuls are accredited as representatives of "his imperial majesty the tenno of Japan." The first mikado, Jimmu Tenno, who is usually regarded as a historical character, began to reign about 660 B.C., since which time 123 emperors have occupied the throne. The mikado claims divine descent from the gods or kami who created heaven and earth (or Japan). He has no family name, and no mikado ever takes the name of any of his predecessors. The reigning mikado (1875) is Mutsuhito, second son of the emperor Komei Tenno, and the express Fulgiva Askja. He was born in 1850, succeeded his father Feb. 3, 1868, and married Haruko, daughter of Iehijo Tadaka, a noble of the second degree of the first rank, born in June, 1850. (See JAPAN, vol. ix, pp. 542-6.) The "unbroken line of descent through 25 centuries" claimed for the mikado has been made possible and even probable by the existence in Japan of the custom prevalent in Asiatic nations of adoption and concubinage. The mikado is allowed 12 niyoppo or concubines, though the number is rarely filled up. As an additional safeguard against failure of issue, four cadet families of the imperial blood called the shishinpo have long been set apart, from which heirs to the throne might be chosen. The present mikado, abandoning the habits of seclusion practised by his ancestors, appears in public, and gives audience to members of the diplomatic corps in Japan, to his own officers, and to the foreigners employed in the government service. He dresses, eats, rides, and acts like a European sovereign. The real governing power in Japan, however, resides in the dai jo kuun, or supreme council.

MIKLOSICH, Franz von, a Slavic philologist, born at Luttenberg, Styria, Nov. 29, 1813. He studied philosophy and jurisprudence at Graz, and became a teacher in 1857. He was a member of the Austrian parliament in 1848-9, and afterward became Slavic professor in the high school of Vienna. In 1862 he was made a life member of the Reichstag. He has published Radices Lingva Palaeoslavonicnica (Leipsic, 1843); Lexicon Lingua Palaeoslavonica (Vienna, 1850; 2d ed., 1863); Formenlehre der altslavischen Sprache und Lautlehre der altslavischen Sprache (1850); Vergleichende Grammatik der slavischen Sprachen (1852-7) which is his principal work; Chrestomathia Palaeoslavonica (1854 and 1861); Die slavischen Elemente im Neuuireichischen
MILAN
(1870); and Beiträge zur Kenntniss der slawischen Volkspoesie, including Die Volkspëk der Kroaten (1870) and Albanische Forschungen (3 parts, 1871). With J. Müller he edited Acta et Diplomata Graeca Medit.Æevi (8 vols., 1860 et seq.).

MILAN, a central county of Texas, bordered N. E. by the Brazos river, intersected by Little river, and drained by its tributaries the San Gabriel, Brazos creek, and others; area, 1,048 sq. m.; pop. in 1870, 9,984, of whom 2,977 were colored. The surface is generally rolling, in some places hilly and broken, and the soil is mostly fertile. The chief productions in 1870 were 201,117 bushels of Indian corn, 21,381 of sweet potatoes, 21,881 lbs. of wool, 37,549 of butter, and 5,143 bales of cotton. There were 4,548 horses, 4,106 milch cows, 24,706 other cattle, 6,498 sheep, and 16,672 swine. Capital, Cameron.

MILAN (Ital. Milano; Ger. Mailand). I. A province of Italy, in Lombardy, bordering on Como, Bergamo, Cremona, Piacenza, Pavia, and Novara; area, 1,155 sq. m.; pop. in 1872, 1,009,794. The surface in the north is hilly, falling away gradually to the plains of the south. The river Adda bounds the province partly on the E., and the Ticino on the W.; along these streams the land is low and marshy, but on the whole the soil of the province is remarkably fertile. It is divided into the districts of Abbiategrasso, Gallarate, Lodi, Milan, and Monza. II. A city (anc. Mediolanum), capital of the province, in lat. 45° 28’ N., lon. 9° 11’ E., 155 m. W. of Venice, and 78 m. N. E. of Turin; pop. in 1872, 199,009. It lies in a fertile plain S. of the Alps, between the small streams Lambro and Olona, which connect by the Naviglio Grande canal with the Ticino and by the Mortesana canal with the Adda, establishing a communication with the Lago Maggiore, the lake of Como, and the Po. By railway it is connected with the principal cities of Italy. Unlike other celebrated Italian cities, Milan combines remarkable natural and architectural attractions with appearances of comfort and material prosperity; and it is justly regarded as one of the pleasantest cities of Europe. It is nearly circular. The length of the canal which forms the circumference of the most densely populated part is 5 m.; the whole circuit of the modern city is 8 m., and that of the outer wall 10 m., the latter area comprising, besides the city proper and its suburbs, a great number of gardens and orchards. The principal gates are the porta Principe Umberto, opened in 1865, through which all travellers by rail enter the city, and the porte Garibaldi, Nuova, Venezia, Vittoria, Vigentina, Ludovica, Romana, Ticinese, Verceilina (now Magenta, built to receive Napoleon when he came to assume the iron crown), and Tenaglia. The last leads to the Simplon, and opens upon an esplanade called piazza di Castello. The street running all round outside the city is called strada di Circonvallazione. Some of the streets are narrow and winding, but they are generally well paved, and some of the thoroughfares are admirable.

Many streets parallel to and in the immediate vicinity of the canal retain the name of terrazzi or terraces. The piazza Borromeo is adorned with a statue of that saint. The piazza di Castello or esplanade was much embellished by Eugène de Beauharnais during his viceroyalty. The castle is now used as a barracks, and on the N. E. side is the piazza d’Armi. The arco della pace, opening into it, is second only to the arco de l’etoile in Paris; it is a magnificent white marble triumphal arch, principally the work of Cagnola, begun in 1807 and completed in 1818. Close by the piazza d’Armi is the Arena, used for shows and races, and capable of accommodating 90,000 spectators. The most fashionable promenades are the streets called corsi, which lead to the principal gates.

Cathedral of Milan.
The corso Vittorio Emanuele, beyond the porta Venezia, is the most beautiful and the most frequented. Near by is the new public garden, beautifully laid out, and adorned with a bronze statue of Cavour. A magnificent equestrian statue of Napoleon III. was erected in one of the public squares in 1875.—The houses of Milan are generally from three to five stories high. There are not as many sumptuous mansions as in Genoa, Rome, and Florence, but the Visconti, Belgioioso, Annone, and Belloni palaces are fine architectural monuments, containing many works of art. The archiepiscopal palace, the palazzo della Corte (the residence of the king when he visits Milan), the palazzo Marini or of the treasury, the palace of justice, that of the government, the palace of science and art (Brera), the mint, and the famous monte di stato or public loan bank, are among the most remarkable public buildings. But they are all eclipsed by the duomo or cathedral, next to St. Peter's the largest church in Italy. It is almost in the centre of the city, in the piazza del Duomo. It was begun by Giovanni Galeazzo Visconti in 1387, but is not yet finished, although Napoleon I. gave a powerful impulse to its completion. Though the main design has been carried out, the details present inconsistencies and anachronisms. The interior is crowded with monuments of prelates and princes and relics of saints. In fretwork, carving, and statuary, it is said to eclipse all other churches in the world; and the ornamentation is so profuse that much of the value of the details is lost in the mass. (For its dimensions and general description see CATHEDRAL, vol. iv., p. 118.) One of the most remarkable churches is that of St. Ambrose, renowned for its antiquity and as the scene of ecclesiastical councils, political colloques, and the coronation of sovereigns. In the refectory of the ancient Dominican convent, the present church of Santa Maria della Grazie, is the celebrated fresco of the "Last Supper" by Leonardo da Vinci. The church of Santa Maria, near that of San Celso, in the Borgo San Celso, is noted for its beauty. The church of San Carlo Bormone, begun in 1588 and opened in 1847, built after a design of Amati, is surrounded by a dome only second in size to that of the Pantheon, and contains a marble group of the dead Saviour and the Virgin by Marchesi; but the interior is unfinished. Among other notable churches containing celebrated pictures and monuments are San Fidel, San Lorenzo, San Marco, and San Vittore al Corpo, formerly the Basilica Porziana, which vies in dignity with the duomo. Milan abounds with charitable institutions, which possess property to the amount of $40,000,000. The principal of them is the great hospital, 880 ft. long by 360 ft. in depth, founded by Francesco Sforza in the 15th century, open to all applicants for receiving a free dispensary; among other endowments, it has received two legacies, respectively of $800,000 and $1,800,000, from private individuals. Among the other hospitals are the large foundling hospital; the Trivulzi hospital, for the relief of the aged, founded in 1771 by Antonio Trivulzi, who devoted his palace to the purpose; and the lazaretto, the most extensive of them all, situated outside of the walls, founded in 1461 and completed at the end of the century, for the plague-stricken, consisting of four ranges of buildings, each nearly 1,200 ft. long, which enclose an area of more than 30 acres.—Education is represented in Milan by the archiepiscopal seminary, two lyceums, three gymnasia, and a number of colleges and schools, including one for deaf mutes, one for veterinary surgeons, and one for the technological sciences. There are an institute of science, a geographical military institute noted for issuing excellent maps, a collection of zoology and paleontology in the museo municipale di storia naturale, and other establishments and societies for the promotion of science, literature, and art. The intellectual activity of the city has been rapidly increasing since the overthrow of the Austrian rule in 1859, and is particularly evident in the great number of newspapers and periodicals published there. Probably more books are issued in Milan than in any other city of Italy. The Milanese school of engravers has acquired a high reputation within the last 40 years. The academy of fine arts is one of the most celebrated institutions of its kind in Europe, and the palazzo delle scienze e delle arti, in which it is situated (commonly called the Brera from having originally been a Jesuit college called Santa Maria in Brera), is one of the chief ornaments of the city. It contains an extensive gallery of paintings, rich in works by Lombard and Bolognese artists, and the public library of nearly 190,000 volumes, including the works bequeathed to it by Haller; a number of medals and an archæological library; a collection of casts; a botanic garden, and an observatory, one of the best in Italy. The new Victor Emanuel gallery was opened by the king, Sept. 15, 1867. Besides several other special libraries in the Brera, Milan is the seat of the world-renowned Ambrosian library, founded by Cardinal Bormone, and carefully explored by Cardinal Mai, who made there important discoveries of palimpsests. (See AMBROSIAN LIBRARY.) The most extensive private library in Milan is in the palazzo Trivulzi, which contains also a valuable collection of coins, and of Greek, Roman, and medieval antiquities. The theatres and theatrical entertainments at Milan are numerous and excellent. La Scala can accommodate between 3,000 and 4,000 persons. Attached to it is an academy of dancing, and it also contains a sala di ridotto for concerts and balls. Among the other principal theatres are the Canobbiano, the Carcano, the Teatro Re, and the Filodramatico, conducted exclusively by amateurs. The city contains fine coffee houses, club houses, hotels,
elegant shops, and a magnificent bazaar (galleria di Cristoforo). Milan has been the seat of an archbishop since the time of the last Roman emperors. The fortifications, consisting of a bastioned wall and other works, form an irregular polygon, and are not strong enough to withstand a siege. In the inland trade, the commercial activity is greater than that of any other city in Italy. The principal articles of commerce are silk, grain, rice, and cheese. The manufactures of silk goods, ribbons, felt and silk hats, turners' work, cutlery, and porcelain are important.—Ancient Milan (Medi- lanum) was the chief place of the Insubres in Cisalpine Gaul, and for a long time the capital of that province. It fell into the hands of the Romans about 222 B.C. Under the empire it advanced rapidly in prosperity and in political and intellectual importance. It became the capital of the Lombard kingdom, and was allotted to Basilius of northern Italy radiated its admirable position midway between the Alps and the Po made it the natural capital, and it was the imperial residence of Maximian and some of his successors for the greater part of the 4th century. By his edict issued at Milan in 313 Constantine granted tolerance to the Christians. St. Ambrose was bishop of Milan more than 23 years, till his death in 397, and his personal influence made it the metropolis of the empire in Lombardy. Several councils were held there in the 5th century, and several others in later times. In 452 the city was plundered by Attila. It next became the capital of the Gothic kings, and was recovered by Belisarius in 537, but taken by the Goths in 539, and almost entirely destroyed and nearly depopulated. In 569 it was occupied by the Lombards, and in 774 it came into the possession of Charlemagne. Several of his successors assumed either at Milan or at Pavia the iron crown. After the coronation of Otho I. in 961 Milan formed part of the German empire, and its governors were appointed by the emperors. The city was besieged by Conrad II. in the early part of the 11th century, on account of the attempt of Archbishop Heribert and others against the imperial authority. In the 12th century, when Milan was the most wealthy, populous, and influential city in Lombardy, it became the principal opponent of the German emperors, and was twice besieged by Frederick Barbarossa (in August and September, 1158, and again from May, 1181, to May, 1182). The latter siege it was almost entirely destroyed. Recovering from the effects of this calamity, it was declared a free city after the victory of the Lombard league at Legnano in 1176; and although pledging itself by the treaty of Constance (1183) to recognize the German emperors as chief feudatories and magistrates, it was permitted to withhold from them the revenues of the immense municipal domains. The efforts of the citizens to liberalize their institutions were thwarted by the conflict between the Ghibellines and Ghibelines, the political influence being divided between the family Della Torre, the representatives of the former, and the Visconti, of the latter party. The Della Torre were successful in monopolizing the office of podestà or chief magistrate from 1237 to 1311, when a revolt against the emperor Henry VII. brought the Visconti into power. Matteo Visconti and his successors extended the power of Milan over almost all parts of Lombardy, and in 1385 it became the capital of the duchy of Milan, the first duke being Giovanni Galeazzo Visconti. After the extinction of the male line of the Visconti family (1447), Francesco Sforza, the husband of an illegitimate daughter of the last of the Visconti, secured the duchy for himself and his descendants. The claim of France upon Milan, derived from internmarriage with the Visconti, was taken up by Louis XII. (1499), and more strongly still was speedily opposed by the emperor Charles V.; and the duchy was alternately in the hands of the French and of Sforza until Francis was obliged to relinquish his pretensions by the treaty of Madrid (1526). Francesco Sforza II. having received Milan in fief from Charles V., it reverted to that emperor after the extinction of the male line of the Sforzas (1550); he gave it to his son Philip II., and it remained in the power of Spain for nearly two centuries. From the end of the 14th to that of the 16th century Milan was celebrated for its manufactures of arms and armor. The city was equally renowned for the elegance and tastefulness of its finery, and became so noted as a leader of fashions in Europe that the English word milliner originated from Milane, an importer of fashionable articles from Milan. In 1576 the city was desolated by the plague. At the close of the war of Spanish succession the duchy was allotted to Austria (1714), and constituted together with Mantua the Austrian portion of Lombardy. After the invasion of the French in 1796 it became part successively of the Cisalpine republic (1797), of the Italian republic (1802), and of the kingdom of Italy (1805). In 1814 it became a province of Austria and part of the Lombardo-Venetian kingdom. Soon after the French revolution of 1848 Milan became the scene of disturbances; and after the departure of the viceroy, Archduke Regnier, a violent insurrection broke out, in consequence of which Gen. Radetzky, commander of the Austrian troops, marched into the city, which was occupied by the Piedmontese, who established a provisional government. After the defeat of Charles Albert at Custozza (July 25) the republicans of Milan overthrew the provisional government; but on Aug. 5 the city was compelled to submit to Radetzky, who entered it with 50,000 men, and kept it in a state of siege till December. The disturbances of March, 1849, and the rising of Feb. 6, 1859, were speedily suppressed. The rule of Austria was brought to a close in 1859 by the French and Sardinian armies; and the
Austrian troops evacuated Milan June 5, the day after the battle of Magenta. Napoleon III. and Victor Emanuel made their entry into the city June 8, and by the peace of Villafranca (July 11) Milan and the rest of Lombardy were ceded by Austria to France, to be transferred by the latter to Sardinia. The city was the scene of some disturbances by Neapolitan soldiers, April 29 and 30, 1861, but these were soon suppressed.

**MILAZZO**, or **Melazzo** (anc. Mylas), a seaport town of Sicily, on the N. coast, in the province and 18 m. W. of the city of Messina; pop. about 7,000. It is built on a promontory which forms a spacious bay, the Basiliciana of the ancients, affording excellent anchorage, and is divided into two parts, one on the promontory strongly fortified, and the other at the harbor near the bottom of the bay. The exports are fish, wine, oil, olives, and fruits of every kind. The tunny fishery is considerable. The plain of Milazzo, bounded by the mountains of Peloritani, is noted for its beautiful scenery. The promontory of Milazzo was the scene of a victory of the Roman fleet over that of the Carthaginians in the first Punic war, 260 B. C., gained by means of the grappling implements called **corvi**, then used for the first time. In 36 Agrippa, the commander of Octavius's fleet, defeated there that of Sextus Pompey. In 1719 Milazzo was unsuccessfully besieged by the Spanish army. On July 20, 1860, Garibaldi here defeated the Neapolitans, a victory which resulted in giving him possession of Messina.

**MILBURN, William Henry**, an American clergyman, born in Philadelphia, Sept. 26, 1823. In early childhood he lost the sight of one eye wholly and of the other partially, and in later life consulted the most eminent oculists in Europe and America, but without avail. At the age of 20 he became a Methodist Episcopal clergyman, and during several years of itineracy travelled more than 200,000 miles in the United States. In 1856 he was chaplain of the house of representatives at Washington. In 1859 he visited England in company with Bishop Simpson and the Rev. Dr. McClintock, and delivered lectures in the principal cities. Subsequently he was ordained in the Protestant Episcopal church, but in 1872 he returned to Methodism. He has published "*Rifle, Axe, and Saddle Bags*" (1857); "*Ten Years of Preacher Life*" (1859); and "*Pioneers, Preachers, and People of the Mississippi Valley*" (1860).

**MILDEW** (Ang.-Sax. *mildæc*; Ger. *Melthau*, meal dew), a name applied to various minute fungi, especially by agriculturists and horticulturists to those which are found upon and are injurious to their crops. The name was originally applied to the white moulds; in common use it is not restricted to these, but designates also dark-colored fungi, and those of different genera and sub-orders. (See *Fusci*.) One of the most widely disseminated mildews is that which attacks the grape vine, appearing as grayish spots upon the under surface of the leaves, the young shoots, and the stems of the fruit; it often destroys the foliage, and consequently the fruit fails to ripen. It has produced incalculable damage to the vineyards of Europe as well as of this country, and though some varieties are more susceptible to its attacks than others, almost all in certain seasons are affected. An English gardener, Mr. Tucker, gave special attention to the subject, and the fungus, in acknowledgment of his services, was called *oidium Tuckeri*, a name by which it is generally known in horticultural works; but Dr. Berkeley, a high authority in cryptogamic botany, considers it not an *oidium*, but a form of an *erysiphe*, a very polymorphous genus, in which there are five different kinds of fructifications. Whether this view be correct or not, the plant is now quite well understood, as are the means of combating it. With grapes grown under glass, where the cultivator can control the humidity of the atmosphere, mildew is easily managed; but in the open vineyard it demands constant vigilance, and the vineyardist should daily examine the vines most liable to its attacks, and at the first indication of its presence apply sulphur. In some of the wine-growing districts of Europe sulphuring is practised systematically, whether mildew appears or not. With a view to destroy the spores, the vines before the buds swell and the trellises are sprinkled with a solution of 8 1/2 oz. common salt and 4 oz. saltpetre in 36 oz. of water, and 10 drops each of oil of rosemary and lavender are added; one part of this is mixed with 100 parts of water and thoroughly applied by means of a syringe. As soon as the leaves expand they are well dusted with flowers of sulphur, for the application of which a bellows has been especially contrived which blows the sulphur ash a cloud of dust, and when the bellows is properly handled every part of the vine will be powdered with it. A similar application is made when the vines are in blossom, another when the grapes are as large as a pea, and a fourth when they begin to color. In this country the grape growers generally content themselves with using sulphur at the first appearance of the trouble. Its efficacy is well established, provided it be applied in time. Mildew usually appears upon the grape in prolonged warm and damp weather, and it often follows a sudden change of temperature.—Rose growers are sometimes great losers by mildew; the leaves become parched and blistered, and the young stems and unexpanded buds are misshapen and covered with a gray mould; this is attributed to a different plant of Fungi. (Fungi.)

---

**Grape-vine Mildew.**
from that upon the grape, *spherotheca pannosa*. A similar blight comes upon hop vines, often seriously affecting the crop. Cucumbers, lettuce, and other succulent vegetables are injured in a similar manner in unfavorable seasons; and in this country a late crop of peas is almost impossible by reason of an *epysiphe* which covers the foliage in such abundance that the plants appear as if dusted with a white powder; the European pea mildew or blight is *E. Martii*, but we are not aware that our species has been identified as the same. The pea is also attacked by another fungus, *peronospora*. 

**Pea Mildew (Leaflet natural size, Fungus magnified).**

**Vicia.** Near large cities immense quantities of lettuce are forced under glass, to supply the demand during winter; were there no difficulties to contend with, this would be an exceedingly profitable culture, but often the grower finds his crop, just as it is nearly ready for market, rendered almost worthless by the advent of a mildew or mould. *Peronospora gangliiformis* is one of the destructive lettuce fungi, but it is probably not the only one. As with other plants under glass, lettuce is usually attacked by mildew after a sudden change of temperature, and all the grower can do is to preserve the proper conditions of heat and moisture as preventives, for when it is established there is no remedy.—The most important of these minute fungi is the wheat mildew, or rust as it is more generally called in this country, *pucinia graminis*, of which figures are given in the article Fusion. This obstacle to successful wheat growing has been known from very early times, but its real nature was only discovered early in the present century. With a view to destroy any spores that may be with the grain, it is common to treat the seed wheat with a solution of sulphate of copper. —There is scarcely a cultivated or wild plant which is not in some seasons the host of these fungi, which arc so minute that their structure can only be seen by the aid of strong magnifiers; in one sense they are among the most important plants to the cultivator, and often determine his success or failure; the minute mildew of the grape in the wine regions of Europe has brought ruin to whole neighborhoods and driven families to emigration. —Another set of fungi attacks dead vegetable matter. When linen or cotton fabrics are kept in a damp place or laid away before they are perfectly dry, they become covered with dark spots which the housekeeper knows as mildew; this is a species of *cladosporium*, which in some of its forms attacks the leaves of the apple and pear, and also produces the dark blotches sometimes found on otherwise fair specimens of the fruit. Paper, whether upon damp walls or stored in a damp place, is attacked by a *chetonium*, an *acrosithia*, or some other form of mildew, and similar fungi appear upon damp plastered walls. (See Fixina."

**MILE** (Lat. *mille passuum*, 1,000 paces of 5 ft. each), a measure of length or distance. According to the estimates of the length of the Roman foot, the ancient mile must have been 1,614 or 1,618 English yards, while the English statute mile amounts to 1,760 yards or 5,280 ft. There are 69-16 statute miles to a degree of the equator, and the English geographical mile is \( \frac{16}{15} \) of a degree, or 1,027 statute miles. The distance expressed by the term mile varies; the following are its values in some countries:

**MILETUS**, an ancient city of Asia Minor, situated in the northern part of Caria, but politically belonging to the Ionian confederacy. It stood at the northern extremity of a promontory formed by the Grium range, opposite Priene and the headland of Mycale, and commanding the entrance of the Latmie bay, into which the Meander flowed. Miletus had four harbors, protected by a group of islands, the principal of which was Lade. It is difficult to determine the precise position of the now ruined city, owing to the continued changes produced in the bay and its surroundings by the action of the Meander, which, bringing down immense masses of soil, has filled up the northern portion of the water basin, and changed Lade and the other islands into parts of the continent. The territory of Miletus extended round the bay as far as the promontory of Mycale on the north and Cape Posidium on the south. The earliest inhabitants were Carians, Leleges, and Cretans, and it derived its historical name from Mile- tus, a leader of the latter, being also called...
Pityusa and Anactoria. It was subsequently settled by Ionians from Greece under the lead of Neleus, the younger son of the last Athenian king, Codrus. It was celebrated as an industrial and commercial city, and in the early portion of Greek history it was the foremost maritime power, extending its commerce and colonies all over the shores of the Mediterranean, the Propontis, and the Euxine. Among its colonies were Naukratis in the delta of Egypt, Sinope in Paphlagonia, Pantikapeum in the Taurian peninsula (Crimea), and Odessus, Olbia, Tomi, and Istropolis, on the W. shores of the Euxine. At the same period it also occupied a dignified place among the most enlightened cities of Ionia, being the birthplace of the philosophers Thales and Anaximander, and of the historians Cadmus and Hecataeus. It successfully defended its independence against Sadyattes and Alyattes of Lydia, but succumbed to the last monarch of that kingdom, Croesus; and after his fall it was subdued by the army of the Persian conqueror under Harpagus. Under Aristagoras, the brother-in-law of its governor Histiaeus, it revolted with the other Ionian cities against Darius Hystaspis, receiving aid from the Athenians, but was finally subdued and destroyed by the Persians (494 B.C.), the great revolt leading to the first invasion of Greece. Recovering under the later Persian kings, it vainly defended the cause of the last of them against Alexander (334), and suffered a new ruin. Having belonged for about a century to the Seleucids, it was annexed to the territories of Rome after the defeat of Antiochus the Great, and shared the fate of the other cities of the province of Asia, dwindling away under the Byzantine rule, until it was totally destroyed by the Turks. For some years excavations have been conducted at the cost of the Rothschilds, who in 1873 presented to the administration of the fine arts in Paris several columns and sculptures from the temple of Apollo Didymus. Remains of an aqueduct and of several temples have been found.

**MILFORD**, a town of Worcester co., Massachusetts, on the Milford branch of the Boston and Albany, and on the Milford and Woonsocket and the Hopkinton railroads, 30 m. S. W. of Boston; pop. in 1870, 8,890. It is one of the largest boot manufacturing towns in New England, and contains machine shops and other manufactories, a national and a savings bank, a weekly newspaper, and six churches.

**MILFORD HAVEN**, a harbor of Pembroke-shire, Wales, the deepest, safest, and most commodious in Great Britain, formed by an inlet of St. George’s channel, N. W. of the entrance to Bristol channel. Its opening is toward the south, but after penetrating a short distance inland it changes its direction and runs east, branching off into numerous bays, creeks, and roads. It is about 10 m. long and from 1 to 2 m. wide, and is defended by two batteries. The tides rise from 28 to 30 ft., and at low water it contains as great an area of deep anchorage as the aggregate of Plymouth, Portland, and Holyhead. It has substantial docks and piers, and is a great resort for shipping. A royal dockyard was established here in 1790, but it was removed to Pembroke in 1814. The number of entrances at the port in 1871 was 31, tonnage 8,190; clearances 5, tonnage 2,188. The imports from the United States in 1871 were valued at £2,651, from other countries £24,355. Milford (pop. in 1871, 2,530) is a
modern place, and is engaged chiefly in ship building. It is connected by rail with the South Wales line.

MILFORT, Le Cieare, a French adventurer, born in Mecéres about 1759, died there in 1817. He came to America, travelled through the British colonies, and about 1776 visited the Creek nation. Here he attached himself to the Creek chieftain, Alexander McGillivray, whose sister he married. He was made a war chief by the Indians, and performed active service against the whigs of Georgia during the American revolution. He remained with the Creeks for 20 years. In 1796, having lost his wife and his friend and brother-in-law McGillivray, he returned to France, and was made a general of brigade by Bonaparte. He married again in France, distinguished himself in 1814 by a gallant defence of his own house in Vouziers, whether he had removed from Mecéres, against a party of Russians, and soon afterward returned to Mecéres. He published Mémoires, ou coup d'ceil rapide sur mes voyages dans la Louisiane, et mon séjour dans la nation creeke (5vo, Paris, 1802).

MILHAI. See MILLAI.

MILITARY FRONTIER (Ger. Militärpresse; Hung. Hadtró-tádak), a region, and formerly a political division, of the Austro-Hungarian monarchy, between lat. 44° and 47° N., and lon. 14° and 23° E., bounded N. by Carniola, Croatia, Slavonia, and Hungary, E. by Transylvania and Roumania, S. by Servia, Bosnia, and Dalmatia, and W. by the Adriatic; area, about 13,000 sq. m.; pop. in 1870, 1,041,123. Its breadth is greatest in the W. part, which is traversed by continuations of the Julian Alps, branches of which are the Great and Little Capella ranges, and by the Dinaric Alps, while the easternmost division is crossed by offshoots of the S. E. Carpathians. The middle parts are mostly level and exceedingly fertile. The highest elevations are Mounts Gugn (7,700 ft. high) and Sarka (7,300 ft.), near the Transylvanian boundary, and Mount Klek or Ogulin Head (Ger. Ogutiner Kopf), near Zengg on the Adriatic (6,900 ft.). The principal rivers are the Danube, which traverses the country in a S. E. direction between Peterwardein and Semlin, continuing its course E. on the southern frontier as far as Orsova, and receiving the waters of the Theiss, the Bega, and the C rage; the Save, which separates the Military Frontier from Bosnia and Servia, and falls into the Danube between Semlin and Belgrade in Servia; and the Kulpa and the Unna, affluents of the Save, flowing respectively on the confines of Croatia and Bosnia. There are some mountain lakes in the W. part. Of mineral waters, the sulphur springs of Mehádia, near the confines of Wallachia, are most celebrated, the place being also famous for picturesque scenery. The climate is very mild in the level country, but severe in the mountains. The principal productions are the various kinds of grain, maize, tobacco, flax, hemp, fruits, and wine; and of minerals, silver, iron, copper, lead, and some gold. The inhabitants are mostly of Slavic race, Croats, Slavonians, Serbs, &c.; but there are also Wallachs, Magyars, Germans, Greeks, Jews, Clementines (Albanians), and gypsies. The predominant religions are the Greek and the Roman Catholic, the former having its centre at Carlovitz on the Danube, the seat of a patriarch or archbishop. There are few towns, but some of them, as Peterwardein, Carlovitz, Semlin, Pancsova, and Old Orsova, all on the Danube, Zengg, Carlopoago, and Brod, in the western division, and others, are important on account of their situation.—The country was originally formed into a military organization by Ferdinand I. (died in 1504) as a barrier against the Turks, and it was reconstituted in 1807 and again in 1850. Under the military organization almost the entire male population above 20 years of age was formed into 14 regiments of infantry, 1 of hussars, and 2 battalions of boatmen. All agricultural estates were the common property of the Frontier communities, the rural buildings being partly inalienable and partly individual property. Arms, accoutrements, and ammunition, and all necessaries during military service, were supplied by the government, and in all military respects the frontiersmen were subject to the rules of the Austrian army.

Before the reorganization of Austria in 1867 the Military Frontier was a separate crown land of the empire. By that reorganization its reunion with the crown of Hungary was virtually established; and at the meeting of the delegations of Cisleithan Austria and Hungary in 1869, it was resolved to abolish gradually the peculiar institutions of the Military Frontier, and to incorporate one of the two military commanderies with Hungary proper, and the other with Croatia. The transformation was nearly completed in 1874.

MILITARY LAW. See COURT MARTIAL, and MARTIAL LAW.

MILITARY SCHOOLS, institutions in which soldiers are instructed or youths educated for the army. Of the former class, the "soldier schools" of Prussia, established in every regiment or battalion, in which the privates are taught the common rudimentary branches, and sometimes singing also, are the most remarkable. There are similar schools in the Austrian, British, and other European armies. Academies of the second class, intended to educate officers, were not unknown in antiquity, and are now an indispensable part of the military system of all great nations. The first military school in France was established by Louis XV, at Vincennes in 1751; it had 500 pupils, all of whom were young noblemen. Soon after its establishment it was removed to the edifice built for it in the Chant de Mars, Paris, and it is still the principal military school of France. The famous school of St. Cyr, near Versailles, was originally founded by Bonaparte at Fontainebleau in 1802, but was a few years later removed to its present location, and still retains the prin-
MILITARY PERIOD

A MILITIA

The military period began when the French had an artillery school in every town where a regiment of that arm was garrisoned, and their example has been followed by Germany and Austria. In Prussia the education of officers is provided for by high schools for each arm in every army division, and by the royal military school at Berlin, founded by Frederick the Great, to which the most deserving young officers are admitted from the line. In Great Britain the royal military college at Sandhurst, which comprises a cadets' college and a staff college, and the royal military academy at Woolwich, designed as an artillery and engineer school, enjoy a high reputation. The United States military academy at West Point, founded in 1802, ranks second to no institution of the kind in the world. Cadets are admitted on the recommendation of members of congress and the president of the United States, and the act of congress of Feb. 2, 1872, increasing the congressional representation of the several states, enlarged the corps of cadets from 293 to 342, the present legal number. The education and subsistence are gratuitous, which is not the case at Sandhurst, Woolwich, St. Cyr, &c. The course of study, under a superintendent and 40 professors and instructors, 32 of whom are army officers, covers a period of four years. Since 1866 the standard of qualifications has been raised, and appointments to cadetships must now be made one year previous to admission. To the end of 1873 about 2,500 had graduated at West Point, and the total cost of the school since its establishment was less than $9,000,000. Apart from West Point, military instruction in the United States is provided for as follows: The act of July 28, 1866, authorized the president, "for the purpose of promoting knowledge of military science among the young men of the United States," to detail officers of experience to act as professors in institutions of learning having upward of 150 male students; and several institutions have availed themselves of such instruction. By the same act provision is made for the instruction of enlisted men in the common English branches of education, and especially in the history of the United States, at every post, garrison, or permanent camp. In 1867 an artillery school was organized at Fort Monroe, to which one battery from each of the five regiments of artillery is ordered every year, for theoretical and practical instruction in that branch of military tactics. In nearly every military department there are now schools of instruction in military signalling and telegraphy, and for this service there is special recruiting. The Virginia military institute, at Lexington, was organized in 1889; in 1873 it had 19 instructors and 260 students; it owns property valued at $300,000, and received an annual appropriation of $15,000 from the state, which appoints a certain number of the cadets. Its course of instruction is similar to that of West Point. The Kentucky military institute at Frankfort, was organized in 1846; in 1873 it had 8 instructors and 78 students; it owns property valued at $75,000, and is controlled by a board of visitors appointed by the governor of the state. Two or three American colleges, like the university at Norwich, Vt., are under a partial military organization, and in several of the private schools throughout the country the pupils wear a uniform and are drilled in the manual of arms.

MILITIA

(Lat. miles, a soldier), a body of armed citizens trained to military duty, who may be called out in certain cases, but may not be kept on service, like standing armies, in time of peace. It differs from the levée en masse in having a regular organization at all times. Some form of militia seems to have existed in England in the time of the Saxons. The yeomen or peasants held their lands on condition of military service, every five hides of ground in most counties being charged with the equipment of one man, and were banded in bodies or companies, the command of which was given to the elders elected by the people in the folknotes. The peasants were enrolled under the banners of their immediate lords, but in case of rebellion or invasion the state had a paramount claim upon their services, and the lords had no further authority over them than the privilege of leading them in battle. The organization of this species of militia has been attributed to Alfred, but it seems certain that a national force called the fyrd, regulated probably by similar principles, existed before his time. Under the Normans the fyrd continued to be maintained simultaneously with the feudal armies, and ultimately it became the source both of the modern British militia and of the sheriff's posse comitatus. It was not till the reign of Edward III. that a statute was passed providing that no militia-man should be sent out of his own county except in case of invasion or other grave danger to the realm, nor out of the kingdom in any case. In the fifth year of Henry IV. a law was enacted empowering the king's "commissioners of array" to array and train all men-at-arms, to cause all able-bodied men to arm themselves according to their substance, to amerce those unable to bear arms, and to require the services of persons so armed at the seashore or elsewhere in season of danger. The command of the militia was often given to the persons charged with these commissions of array, but more frequently it rested with the sheriffs or high constables, each in his own county. Such was the organization of the militia when the parliament of Charles I. in 1642 passed a bill vesting the control of this
force, as well as the command of all the forts, castles, and garrisons, in certain commissioners in whom they could confide. The king refused his assent to the bill; and when the parliament thereupon declared the kingdom in danger and issued orders to muster the militia, he issued commissions of array to some of the nobility for the same purpose. Thus began the civil war. After the restoration, the peculiar state of things which had sprung from feudal tenures no longer existed, and the militia was reorganized mainly on its present basis. The king was acknowledged as its sole supreme commander, and no other army was recognized by the law. Lords lieutenant of counties were charged with raising the force, as they had been indeed since the time of Queen Mary; every man who possessed a landed estate of £500 a year, or personable property, to the amount of £6,000, was bound to provide, equip, and pay one horseman; every man whose property was one tenth of either of those amounts was charged with one pikeman or musketeer; and smaller proprietors united to furnish a soldier, each contributing according to his means. But it was not until 1777, when a bill to reconstruct the militia was passed, that the force acquired much vitality. The act then passed, though amended several times, is in its main features still in force. The able-bodied men of each parish between the ages of 18 and 35 are enrolled annually, and by ballot a certain required number are to be selected for service. Certain classes are exempted: peers, yeomanry, resident members of universities, clergymen, parish schoolmasters, articled clerks, apprentices, seafaring men, crown employees, free watermen of the Thames; in England any poor man with more than one child born in wedlock; in Scotland any man with more than two lawful children and not possessed of property to the value of £50; in Ireland any man with more than three lawful children, who pays less than £5 a year rent, or has less than £10 of property. Substitutes may be accepted for the men chosen by ballot, and for many years it has been customary to suspend the ballot, and make up the requisite number by volunteering. The time of service is five years. The command is in the lord lieutenant of the county and his deputies under commission by the crown. The militia are required to assemble for 27 days' training each year, but in times of peace, the requirement is not strictly enforced. The mutiny law is applicable while they are under arms. The militia cannot be compelled to march out of their respective counties except in case of invasion or actual rebellion, nor in any case to march out of the kingdom. Their pay while in service is the same as that in the regular army. In 1873-’4 the militia force of the kingdom consisted of 133,932 men and 5,066 commissioned and non-commissioned officers, of whom the only about one half appeared on the day of inspection. There are also volunteer organizations consisting of: 1, yeomanry cavalry, numbering about 15,000; 2, infantry, artillery, &c., including enrolled pensioners, numbering 193,750. These are only liable to be called out in case of actual or apprehended invasion, for service within the kingdom.—In France all able-bodied males are liable to military duty from the age of 20 to that of 40; the first five years in the active army, then four years in the reserve, then five years in the territorial or district army, and then six years in the territorial army of the reserve. Exemptions are made as follows: the eldest of orphans having neither father nor mother; the only or oldest son or grandson of a widow or wife separated from her husband, or of a father more than 70 years old; the elder of two brothers liable to service at the same time; the younger of two brothers when the elder brother is actually in service in the army; the younger son of a family, whose elder brother has died in the service, or been discharged for wounds or illness contracted in the field. There are also partial or conditional exemptions of pupils, teachers, ecclesiastics, &c.; and the local authorities may grant further exemptions, subject to the revision of the military councils, of young men who contribute to the support of their families, and who are engaged in studies or vocations which would suffer from the interruption. (See Guard, National.)—In Switzerland a standing army is forbidden by the constitution. Military instruction is given in the schools, though not made compulsory. The military forces are divided into: 1, the Bundesauszug, or federal army, consisting of all able-bodied males between the ages of 20 and 30; 2, the army of the reserve, consisting of all between the ages of 31 and 40 who have served in the first class; 3, the landwehr, or militia, embracing all the men from 41 to 45. Their numbers in 1872 were: of the first class, 84,389; of the second, 50,069; of the third, 65,981; total, with the staff added, 201,357. The federal army and the army of the reserve are drilled once a year in their respective cantons, and they also meet once or twice a year in general muster. In Belgium the militia includes all males able to bear arms between the ages of 21 and 40, and they number about 125,000 regular militia and 276,000 reserves. The regular army is supplied by conscription, to which citizens become liable at 19. In the Netherlands the regular army is kept up by conscription of those who have reached the age of 20. The militia consists of those between 25 and 55, who for the first ten years are called active, and afterward the "resting" militia. In Denmark all able-bodied males who have reached 21 are liable to serve eight years in the regular army and afterward eight years in the army of the reserve. The national militia of Sweden is raised and paid by the landowners, assisted to some extent by the income of state domains. The infantry practise a month annually, and the cavalry 45 days.
—The militia system of the German empire is the most complete and effective in the world. Every subject becomes liable to military duty on reaching the age of 20, and he must serve three years in the regular army, and afterward four years in the army of the reserve. After this, at 27, he enters the landwehr or militia, where he remains for five years, liable to be called upon for regular drill, and in case of war to be incorporated in the regular army. Finally, at the age of 32, he is enrolled in the landsturm, where he is subject to military duty within the realm in case of invasion. The reserve, when necessary, are capable of being mobilized for service in two weeks' time. On a war footing the army, according to the latest returns, falls a little short of 1,300,000.—In the Austro-Hungarian monarchy the standing army is formed by conscription of those who have reached the age of 20, and those drawn serve three years in the regular army and seven years in the army of the reserve. The obligation to serve in the landwehr is general, and the period of service is 12 years, but is limited to the respective divisions of the empire from which the body is drawn. There is also the landsturm, corresponding to that of Germany, but enrollment in it is not compulsory except in Tyrol and on the exposed frontier. The army in 1873 numbered on a peace footing 278,478, and on a war footing 588,700.—In Russia all who have reached the age of 21 are liable to conscription for seven years' service in the regular army, and eight years in the reserve. The regular army in 1872 consisted of 765,872 on a peace footing, and 1,213,959 on a war footing. In peace only so many are kept embodied as are necessary to keep the army on the proper peace footing, and the remainder are on furlough. Besides these, the militia is organized whenever emergencies render it necessary. The Cossacks perform military service in lieu of the payment of taxes, and in case of necessity every man from 15 to 60 is liable to serve. —In Italy the regular army is kept up by conscription of those of the age of 21, and those not drawn pass into the army of the reserve, where they practise annually for 40 days, and then are on furlough, subject to be called upon in the event of war. The strength of the army is about 200,000 on a peace footing and 450,000 on a war footing. —In Turkey every man is liable to serve four years in the regular army, and then for two years longer to remain subject to summons for like service; afterward he enters the first reserve for three years, and then the second reserve for three years, after which he passes into the sedentary army, liable to be called out only in time of war. The total available force in time of war is estimated at 700,000. —The militia system of the United States, like that of Great Britain, had its origin in jealousy of standing armies, and the purpose of its establishment was to provide a military force that should be ready and effective for all sudden emergencies, but only required to serve when the emergency should arise. The constitution of the United States confers upon congress authority to provide for calling forth the militia to execute the laws of the Union, suppress insurrection, and repel invasion, and also to provide for organizing, arming, and disciplining the militia, and for governing such part of them as may be employed in the service of the United States, reserving to the states respectively the appointment of the officers and the authority of training the militia according to the discipline prescribed by congress. It also makes the president commander-in-chief of the militia of the several states when called into the service of the United States. Acting under the provisions of the constitution, the congress of 1795 passed an act for the enrollment in the militia of all able-bodied white male citizens of the age of 18 and under 45, excepting the judicial and executive officers of the federal government, members of congress, and officers of congress, and clerks, persons employed in the postal service, inspectors of exports, pilots and mariners, and such persons as should be exempted by state laws. Each person was to be provided with suitable arms and accoutrements, which were made exempt from taxation, and from all process for the collection of debts. The organization was to be effected within one year, under state laws and under officers of state appointment. The act provided that in the organization there should be infantry, cavalry, and artillery in suitable proportions, and designated the number and grade of officers for each division, brigade, regiment, battalion, and company. Another act, passed Feb. 28, 1795, empowered the president, in case of invasion or imminent danger thereof, to call forth the militia of the state or states most convenient to the place of danger or scene of action, as he might judge necessary, and in case of insurrection in any state against the government thereof, on the application of its legislature or of its executive when the legislature could not be convened, to call forth such militia of any other state or states as he might deem necessary to suppress such insurrection. The president was also empowered by the same act, whenever the laws of the United States should be opposed or the execution thereof obstructed in any state by combinations too powerful to be suppressed by the ordinary course of judicial proceedings, or by the marshals, to call forth the militia of such state, or of any other state or states, as might be necessary, to suppress such combinations and cause the laws to be duly executed; and while in service the militia were to be subject to the rules and articles of war, as in case of regular troops. These provisions still remain in force, except that in providing who shall be enrolled the word "white" was stricken out by act of March 2, 1867. The act of 1795 limited the
period of service which the militia might be compelled to perform under such call to three months, but by act of July 29, 1861, when called out to suppress insurrection or assist in enforcement of the laws, it was provided that their continuance in service should not extend beyond 60 days after the commencement of the next regular session of congress, unless congress should expressly by law provide therefor. And the act of July 17, 1862, provided that whenever the president should call forth the militia he might himself fix the period of service, not exceeding nine months. All these acts contemplate that the officering and disciplining of the militia shall be by state authority, and the states have assumed this duty, and made provisions for its discharge. The exemptions from military service under state laws are few, and are confined in the main to members of the executive and legislative departments of the government, judges and clerks of courts, clergymen, teachers, regular physicians and surgeons, superintendents of hospitals, &c., justices of the peace, and active firemen. The state constitutions will be found in general to recognize the value of a well regulated militia in a free government, and to require the passage of laws for organizing, arming, equipping, and disciplining the freemen of the state who are subject to military duty. Every state has laws for that purpose. The governor is the commander-in-chief, and under him are the usual officers, chosen by different modes in different states; in some by the governor alone, in some by the governor with consent of the senate, in some by the legislature, and in some by the persons liable to military duty. For many years it was customary to have annual drill or training days for the whole body of the militia in the several states, and they were called out for the purpose and compelled to attend under penalty; but for 30 years or more the conviction has been spreading that these annual trainings were of little value, and that they accomplished almost nothing in fitting men for active military duty. The consequence has been that the laws providing for them have generally been either repealed or allowed to fall into disuse, and in their place have been substituted provisions under which voluntary organizations are formed, which select their own uniforms and the branch of service to which they will attach themselves, and which are encouraged by small state bounties to perfect their drill and keep themselves in readiness at all times for prompt and effective action. These organizations compose but a small part of the whole body of the militia, but they are ample for all the needs of government in ordinary times, and in extraordinary emergencies they serve as the nucleus of an army until the unorganized militia, or such portion thereof as may be called for, can be put into the field. The militia of the United States at the present time therefore consists of these voluntary organizations, fully officered, armed, equipped, and drilled, and also all other able-bodied male citizens of the age of 18 and under 45, with the exceptions provided by national and state laws, all of whom are subject to be summoned to perform military duty according to the laws of congress or of their respective states.—The militia has sometimes performed a conspicuous part in the military history of the country, though not always to the satisfaction of those who are disposed to rely upon it as the chief protection of the government. During the revolution the militia of the several states was often called out, but the want of discipline, which could not be adequately supplied during the short periods of their service, rendered them an unsatisfactory reliance. The "whiskey insurrection," as it was called, of 1794, was put down by a levy of militia from Pennsylvania, New Jersey, Maryland, and Virginia. During the war with Great Britain of 1812-15, the inefficiency of the militia was increased by disputes between the national and state authorities regarding the right of the president to determine finally whether an emergency had arisen which authorized his calling them out, the right to place them under officers of the president's appointment, and the right to march them beyond the limits of the state. The militia of Massachusetts and Connecticut, when called out, were refused payment by the general government because they had not been placed under the orders of the federal officer, and the militia of Vermont were at one time summoned home by the governor because in his opinion no cause existed which justified the president in demanding their services. The judicial decisions were in favor of the right of the president to decide finally and conclusively whether the militia should be summoned (Martin v. Mott, 12 Wheaton, 19); and his right to place them under the command of a federal officer ranking their own officers is now undisputed. On the breaking out of the civil war in 1861, the militia organizations of some of the states proved of the very highest importance, as they enabled a formidable force to be placed in the field much earlier than would otherwise have been possible. The first call of the president for 75,000 men was mainly filled from this source. Afterward volunteers were relied upon in the main, and when the supply from this source proved insufficient, conscription was ordered. As the laws now are, the great majority of all the persons liable to perform military duty in the United States are unlikely to be summoned for discipline, or even to organize for the purpose, unless the military needs shall require a heavy force in the field, in which case, if summoned at all, it will be by conscription.

Milk, the liquid secreted by the mammary glands of female mammals. Its color is generally yellowish white, but sometimes bluish white, and it is quite opaque. Its specific gravity, according to Scherer, varies from 1.018 to
1°045. According to Simon, the average specific gravity of human milk is 1°038. There is a difference of opinion among chemists as to whether normal milk has an acid or an alkaline reaction. According to Berzelius, Peligot, and Lassaigne, it is acid; Simon and others regard it as alkaline, and attribute the acid reaction found by others to its having acquired acidity by standing, or to disease. Numerous examinations, however, seem to indicate that healthy milk may be alkaline, neutral, or acid, according to the food of the animal. D'Arat and Petit say that the milk of stilled-fed animals is always acid, and becomes alkaline only when they are turned out to grass.

Hermstädt found milk that had remained long in the udder acid. Fraas had a cow milked six times a day, and found the milk at each time feebly alkaline. After an interval of 24 hours she was again milked, when the first portion of the milk was found alkaline and the last portion acid. The opacity of milk depends upon numerous yellow microscopic globules of a fatty substance from 

\[ \frac{1}{10} \text{inch} \] to 

\[ \frac{3}{10} \text{inch} \] in diameter, shown in Fig. 1. According to Chevreul, cow's butter is composed of stearine, margarine, and oleine, with small quantities of butyric, caproine, and caprin; but late analyses by Heintz and others deny the existence of margarine, saying that it consists of palmitine and a small quantity of stearine, together with small quantities of glycerides, yielding by saponification myristic and butyric acids. (See Butter.) In regard to the size of the butter globules observers differ. Dr. Carpenter gives their diameter as 

\[ \frac{1}{10} \text{inch} \] to 

\[ \frac{1}{25} \text{inch} \] and Dr. Dunglison adopts this measure. Dr. Dalton says: "The largest of the globules are not over 

\[ \frac{1}{200} \text{inch} \] in diameter." According to Dr. Bennett, their diameter varies from 

\[ \frac{1}{200} \text{inch} \] to 

\[ \frac{1}{20} \text{inch} \] in an inch. There has recently been considerable discussion as to the existence of an envelope, or "membrane" as some term it, around the globules. Dr. Von Baumhauer and F. Knapp assert that they have none, and others concur with them. Dr. Bennett and others maintain that either a caseous or an albuminous envelope exists, and experiments are cited as sustaining this opinion. The taste of milk is bland and sweetish, and it has a peculiar animal odor, depending somewhat upon the animal, but perhaps still more upon the food. Garlic, even if the plant is partaken of in very small quantities, is distinctly perceptible by the smell as well as by the taste. Milk has always been an article of man's diet, and forms the entire nourishment of the early existence of all mammals; and it contains all the elements necessary for the growth of the animal framework.—In comparing milk of the same animal under different conditions of age, health, food, length of time after parturition, &c., as remarkable differences in the proportions of the ingredients will be observed as when samples of the average milk of several different species of mammalia are compared. The following table exhibits the composition of several kinds of milk, the first column presenting the average result of ten analyses by Prof. Poggiale, the next four being furnished by Messrs. Henri and Chevalier in the Journal de Pharmacie, vol. xxv., and the last by Dr. Samuel R. Percy of New York as the composition of the milk of a healthy woman. The albumen in these analyses is reckoned with the casein.

An analysis by Völicher is given in the article Cheese, and also one of the cheese made from the milk. Of these constituents the most uniform in its proportions is the sugar, but this may be materially increased by the use of saccharine food, as is found in feeding cows upon carrots and beets. The sugar of milk is crystallizable, but it is less sweet and less soluble in water than cane sugar. Milk from unhealthy animals often exhibits an increased proportion of phosphate of lime in the ash. When milk is exposed to a warm temperature it ferments, and lactic acid is generated, which has the same ultimate composition as sugar of milk. Under certain conditions the vinous fermentation may now take place, the sugar of milk be converted into grape sugar, and a spirituous liquor be produced, as is practised by the Tartars. (See Khmira.) Various circumstances affect the quality and composition of milk. That called colostrum, given by the cow immediately after calving, is yellowish, thick, and stringy; for several days it is unfit for use. Examined by the microscope, it is seen to contain numerous large and granular corpuscles. Milk drawn from the cow in the morning is thought to be better than that of the afternoon; and a remarkable difference is perceived in the proportion of cream in the first and last portions of the milking, the latter containing twice as much cream as the same quantity of milk of the former. In the udder of the cow the cream seems to rise as it does when the milk is collected in a vessel.—Some of the methods of testing the quality of milk are noticed under Galectometer. By this the specific gravity is ascertained both of the whole milk and skimmed milk; but as these data are of little value without a knowledge of the proportion of cream,
another instrument, invented by Sir Joseph Banks, and called the lactometer, is used in connection with the galactometer. It is a tube about \( \frac{3}{4} \) in. in diameter, and 10 in. of its length graduated in tenths of an inch. When filled with milk, the tube is set aside for 12 hours for the cream to rise. The proportion of this is then read off in the number of divisions occupied by the upper stratum. The thickness of this stratum is very variable with different sorts of genuine milk; but its general range is from 9 to 14 of the divisions, indicating as many percentages. Dr. Hassal thinks the average of pure milk does not exceed \( \frac{9}{10} \) of cream. Dr. Normandy rates it at 8 to 8\( \frac{3}{4} \). The proportion of cream is also determined by an instrument invented by M. Domné of Paris, called the lactoscope, the principle of which is based upon the opacity of the fluid caused by the buttery particles. A few drops of the milk are introduced between two plates of glass, so set in an ocular tube that they can be brought close together or separated by means of a graduated screw, and thus enclosed at their base a thinner or thicker stratum of milk. The observer then looks through the tube at a light set 3 ft. off, and gradually separates the plates of glass, increasing the depth of the layer of milk, till this at last becomes so opaque that the light is lost to view. The figure to which an index on the instrument then points refers to a table, upon which the corresponding quality of the milk as to quantity of cream is designated. As the large globules of cream are the first to rise, if this is removed the remaining skim milk will contain only the smaller globules; and this has been used in Germany as a means of ascertaining whether milk has been skimmed.—Milk is easily adulterated by substituting various cheap materials for the natural ingredients, thereby seriously affecting its quality, while the fraud can be detected only by the skilful examination of the cream. The vanishing cream is removed and water is substituted. This involves the addition of white thickening substances to disguise the cheat, and of other strange ingredients to restore or retain the sweetness and saltiness of the milk. Large cities are almost hopelessly exposed to these frauds; but worse than all, a large portion of the milk with which they are supplied is that of diseased cows kept in crowded stables and fed with cheap unwholesome food, especially the swill of distilleries. The evil became so serious that several years ago the attention of medical men in New York was directed to the subject, and in 1859 a careful investigation was made into the character and properties of the milk of cows fed upon the swill of distilleries, the results of which are embodied in a report of S. R. Percy, M. D., and published in the "Transactions of the New York Academy of Medicine," vol. ii., part iv. The following are some of the analyses of healthy and diseased milk in that report:

No. 1 is the milk of a cow kept for family use in New York; No. 2, of swill-fed cows from distillery stables in New York; both the analyses are by Dr. Doremus. The following are by Dr. Percy: No. 3, country milk furnished by a dealer to customers in New York; No. 4, milk as drawn from the cows in a Brooklyn distillery stable; No. 5, sample of some delivered to customers; No. 6, another sample of the same as sold to customers; No. 7, milk from a sick cow, Brooklyn distillery stables; No. 8, sample of the milk used by Gail Borden for preparing the "condensed milk." Healthy milk was observed by Dr. Percy to have an alkaline reaction, while that from diseased animals was always acid. The same observation had been made by Gay-Lussac, Berzelius, and others; and the effect is found to be induced in a short time in animals shut out from the light of day, and in those confined in bad air and supplied with bad food. In the analyses, the bad milk is at once recognized by its unduly large proportion of casein, while the sugar and often the butter is as disproportionately small. The large amount of saline matter found in bad milk is caused by the addition of salt made for the purpose of disguising the adulteration with water. But the proportions of the ingredients, though sufficient to expose the character of the milk, cannot indicate the poisonous qualities of the worst sorts, nor the evil effects that may follow their use. In organic compounds, such as we use for food, as in the air we breathe, the most dangerous poisons may lie concealed beyond the power of detection of the most delicate tests or the most powerful microscopes, and their existence is brought to light only by their effects upon the human system. Thus the real nature of the distillery milk is most properly shown in the report by citation of several cases of disease in young children traced directly to its use.—Milk may be impure from natural as well as artificial causes. The microscope affords a pretty good test in both cases, starch granules and chalky particles being easily detected, the latter especially on the addition of a little acid. The simplest cases of diseased milk are those caused by feverishness in the cow. This causes the globules to assemble in groups, as if they possessed a certain degree of vitality somewhat resembling that of blood globules. Fig. 2 shows the microscopic appearance of the globules in feverish milk. Fig. 3 gives the appearance of a sample of milk from a distillery stable in Brooklyn, examined by Dr. Percy. It was taken from a cow very ill
with high fever and inflammation of the bowels. The milk was scanty and blue, and contained, in addition to the broken-down butter globules and spores of confervae, blood globules which are not shown in the drawing. Fig. 4 is a sample of the same milk after standing closely corked for 24 hours. The spores of confervae have grown to perfect plants, with branching stems. These drawings were given in the "Report of the New York State Medical Society" for 1860.—Prof. James Law of Cornell university has made some investigations in relation to fungi in cows' milk, of much practical interest. He arrived at the conclusion that several of the low forms of vegetable life were introduced into the water of which the cows drank, as he found the same forms in the water and also in the blood of the animals. The experiments were made in such a manner as to preclude the possibility of the introduction of the organisms from any other source. The details are given in a pamphlet reprinted from the "Lens," and also in an address on poison cheese before the American dairyman's association in 1872 by L. B. Arnold of Ithaca, N. Y. Prof. Gerlach of Hanover has recently made a series of investigations in regard to the effect of a diet of milk from tuberculous cows, which would lead to the conclusion that tuberculosis may be transmitted in this manner from the bovine to the human race. The subject is at the present time undergoing examination in this country, but no conclusive results have yet (January, 1875) been arrived at.—The preservation of milk from putrefaction is an object of no little importance. In France this is accomplished by causing the solid portion of the milk to combine with other matters, and thus separate in a solid form from the aqueous portion; but the compound is not properly milk. It is also evaporated down to the consistency of sirup, and then by the addition of sugar made into a solid compound of milk and sugar; and by a third method it is preserved by expelling the air from it, and hermetically sealing the bottles while they are under a steam heat of about 100° C. In this way milk has been preserved perfectly fresh for 54 years. In the United States a patent was granted in 1856 to Gail Borden, jr., for another method, which he successfully conducted in Litchfield co., Conn., and afterward in Texas, supplying what is called "condensed milk" to consumers throughout the country. By his process the milk when drawn from the cow is immediately cooled to about 60° F., in order to check its changing. It is soon after rapidly heated in a vat surrounded with hot water to 180° or 190°, when refined white sugar is added in the proportion of about one part to nine of milk. It is kept in the hot water vat about 30 minutes after adding the sugar, and is then removed to vacuum pans in which evaporation of the water is effected at a temperature not exceeding 100°. When it is sufficiently concentrated, the pans are quickly cooled down by passing cold water in the place of steam through the heating pipes. The milk, converted into a paste, can then be removed from the pans without adhering to their sides. Another preparation, known as "solidified milk," is also made by a process like one of the free methods above referred to. To 112 lbs. of fresh milk 28 lbs. of sugar are added, together with a teaspoonful of bicarbonate of soda, merely enough to neutralize any slight acidity. The mixture is then evaporated by the heat of a water bath carefully regulated, and the process is hastened by a current of air made to pass over the surface. An apparatus is kept in operation gently stirring the mixture during the evaporating process, until at last the milk and sugar are reduced to a creamy-looking powder. This when cooled in the air weighed oven, is ground and compressed by machinery into the shape and size of small bricks. These, covered with tin foil, are ready for sale, and are well adapted either for preservation during long voyages or for immediate domestic use. The preparation of condensed milk is conducted upon a large scale in Switzerland.

**Milk, Sugar of, or Lactine, one of the constituen—are of milk. It is prepared in Switzerland as an article of food, and is used by homeopathists as the vehicle for their medicines, and in other practice as an article of food for infants in teething, being less apt to produce acidity than cane sugar. It is also recommended as a non-nitrogenous article of diet in pulmonary diseases. It is prepared from the whey obtained from milk coagulated with a little dilute sulphuric acid, and left several weeks in a cool place to crystalize. The crystals of sugar of milk are collected and decolorized by animal charcoal and repeated crystallizations. They consist of C₄H₁₀O₇·4H₂O. They are hard and gritty, rather insoluble in water and alcohol, slightly sweet, and not easily fermentable. When converted into grape sugar by the action of dilute acids, sugar of milk may furnish a spirituous liquor, as noticed in the
article Milk. By the homoeopathists sugar of milk is regarded as the substance most inert upon the system, and for this reason as well as on account of its great hardness, which causes it to reduce to extreme fineness the substances with which it is ground, they esteem it as the best medium for their medicines, and are by far the largest consumers of it.

MILK LEG, or Phlegmasia Dolens, an obstruction of the veins and lymphatics, causing a painful, non-edematous swelling in one or both lower extremities. It is most common in women after parturition, but it sometimes occurs in unmarried women, and sometimes in males. In the case of lying-in women it usually commences about a week or ten days after delivery, but may take place immediately after labor, or at any time during the next five or six weeks. Any great drain upon the system is liable to be followed by rapid absorption, by which morbid matter contained in the uterus may be taken into the contiguous veins. The pathology consists in inflammation and obstruction of the iliac and femoral veins. The symptoms attending the condition are fever, headache, thirst, nausea, and pain, especially in the lower abdominal and pelvic regions, attended by extreme prostration. The attack may commence with a chill, and within 24 or 36 hours the foot or lower part of the leg may begin to swell, the process extending upward. The acute stage lasts about two or three weeks, and after recovery many deep veins remain obliterated, while the more superficial ones become enlarged and tortuous. The limbs usually remain useless for many months, and often never recover their former condition. As the disease is attended with feebleness, the application of leeches and other forms of blood-letting are generally inadmissible. The most rational treatment is the administration of tonic and diffusive stimulants, combined with alkaline medicines, a bland and nourishing diet (wine and eggs, beef tea, &c.), with the external application of liniments and emollient and alkaline applications, such as soap liniment, bran poultice, and solution of bicarbonate of soda or ammonia.

MILK TREE. See Cow Tree.

MILKWEED, the popular name for plants of the genus Asclepias (named in honor of Asclepius), which includes about 40 species, half of which are North American and the remainder natives of Central and South America. They are all herbaceous plants, with thick deep roots, and mostly with a copious milky juice, bearing their flowers in simple umbels. Few plants present flowers in which the ordinary floral structure is so obscure, and it is not easy to explain them without numerous elaborate diagrams; in general terms it may be said that the parts of the flower are in fives; the five-petaled calyx is persistent; the deeply five-parted corolla is reflexed; immediately within the corolla is a curious structure called the crown, made up of appendages to the stamens, which are themselves united into a tube by their filaments; behind each anther is borne a curious erect hood-like appendage, from which projects a small horn; these appendages are petal-like, and together form a conspicuous portion of the flower; the anthers closely surround and partially adhere to the broad stigma; each anther cell contains a pear-shaped, waxy mass of pollen, and two adjacent masses from two contiguous anthers are suspended by a stalk from a blackish adhesive gland which is borne on the margin of the broad stigma; these pollen masses, by means of the adhesive glands, stick to insects which visit the flowers for honey, and are thus dislodged and borne to other flowers; bees are frequently quite disabled by these pollen masses, which adhere to their legs in such numbers as to prevent them from climbing upon their combs, and they fall down and perish. The ovaries are two, ripening into two large follicles, which open and expose the flattened seeds imbricated over a large placenta, each furnished with a tuft of long, beautiful silky hairs, by the aid of which it may be wafted to a distance by the wind; on account of these silky hairs the plant is frequently called silkweed. The flowers in most species are showy and fragrant, and some are cultivated as ornamental plants; the young shoots of our common species are valued by many as a substitute for asparagus; the bark of their stems is very tenacious, and various partially successful attempts have been made to obtain from them a textile fibre and a paper stock; the plants are not abundant enough in the wild state to afford any considerable supply, and no experiments have been made to ascertain whether their cultivation as a fibre-producing plant would be profitable.

The beauty of the silky down of the seeds early attracted attention, and many attempts have been made to utilize it; but the hairs are very weak and brittle, and without the roughness or angularity which makes it possible to spin other fibres; when mixed with cotton it has been spun and woven into fabrics which have a silky
MILKWEED

lustre and take brilliant dyes, but the manufac-
ture has not been prosecuted; the principal
use made of the down is in the stuffing of pil-
lows.—The common milkweed (A. Cornuti) is
the most abundant species, and is to be found
in rich grounds almost everywhere; although
it is a native of America, Linnaeus called it A.
Syriaca, a name which has been properly su-
perseded; in the southern states it is known as
Virginia swallowwort and Virginia silk plant.
The purple milkweed (A. purpurascens) is a dark-
flowered species; A. variegata has nearly
white flowers; A. incarnata, with fine rose-
purple flowers, is very common in wet grounds,
and is known as the swamp milkweed; the
blunt-leaved milkweed (A. obtusifolia) is a clas-
ping, sessile leaves, and its single umbel of
large but dull-colored flowers; the four-leaved
milkweed, the most delicate of the genus,
blooms in woods in June, and is well marked
by having one or two whorls of four leaves;
A. verticillata, very common on dry hills, has
whorled leaves, which are so narrow as to give
the plant a very different aspect from other
species. The most showy of all our native milkweeds is A. tuberosa, more generally called
butterfly weed and pleurisy root; it is quite
common, especially southward; the root is
large, fleshy, and white; the stems are more or
less decumbent and roughly hairy, very leafy,
and branching at the summit, where it bears
numerous umbels of bright orange-colored
flowers, which are exceedingly showy and al-
low the plant to be distinguished at a great
distance; in this species the juice is scarcely
milky. As one of its popular names indicates,
the plant is used in medicine, the root being
the officinal portion; its action is diaphoretic
and expectorant without being stimulant, and
in large doses is purgative. This plant is much
valued abroad as an ornamental one, and its
roots are a part of the regular stock of the
growers of bulbs and tubers; in this country it
is seldom seen in gardens, but there is no flow-
er of its color capable of producing a more
brilliant effect. Several of our common spe-
cies are valued in European gardens, as is A.
Douglasi, a conspicuous plant from California,
with large leaves, very white with woolly hairs,
and large lilac-purple fragrant flowers. A.
Curassavica, from South America, naturalized
in Florida, with flowers of orange scarlet, is a
common greenhouse plant, and is frequently
set out in the border for summer blooming;
this has emetic properties, and is used in the
West Indies under the incorrect name of ipe-
cauana. Active properties pervade the ge-
inus, and several of the species have a reputa-
tion among the herb doctors.—The genus is
the typical one of the Asclepiadaceae, which
includes more than 130 genera and over 1,000
species. Of the other native genera, the green
milkweeds, of the genus aceratae, differ from
the true milkweeds in the absence of a horn to
the staminal hood. A twining plant, vinca
toxicum nigrum, with very dark purple flowers,
has escaped from cultivation in some places, as
has the Grecian silk, periplocas Grecas, which
is often seen in gardens as an ornamental climber.
From Pennsylvania southward are found sev-
eral species of gonolobus, which are twining
herbs of little beauty. Among cultivated ex-
otics of this family are the wax plants (Hoya
carnosa and other species), with fleshy oval
leaves and umbels of beautiful but artificial-
looking flowers; Stephanotia floribunda, one of
the most valued greenhouse climbers, with fine
foliage and pure white fragrant flowers; and
the singular stapelias, with cactus-like stems
and lurid flowers with the odor of carrion.

MILK WAY. See MILKY WAY.

MILL. I. James, a British philosopher, born
in Logie Pert, near Montrose, Forfarshire,
April 6, 1773, died in Kensington, June 23,
1836. He was educated at the grammar school
of Montrose and the university of Edinburgh,
where he excelled in Greek and metaphysics.
He was licensed to preach in 1798, but aban-
donned the profession, removed to London in
1800, became editor of the "Literary Jour-
nal," which was soon discontinued, and was
an occasional contributor to the principal Brit-
ish reviews. He soon attracted the notice of
Jeremy Bentham, was for several years do-
minated in his house, and was the chief ex-
positor of his opinions in England. On the
establishment of the "Westminster Review" in
1824 by Bentham, Mill became one of its
principal contributors, writing for it important
articles on the "Formation of Opinions," the
For ten years much of his time was occupied in
writing his "History of British India" (3 vols.
4to, 1817-18; continued to 1835 by Prof. H. H.
Wilson, 9 vols. 8vo, 1840-46). It was without
a rival as a source of information; and though
he censured the conduct of the East India com-
pany, his ability and familiarity with its affairs
caused the directors in 1819 to introduce him into their home establishment, where he managed their correspondence with India in the revenue branch of the administration; and he became in time head of the department of Indian correspondence. His official duties did not preclude the continuance of his labors as an author, and he contributed to the supplement to the earlier editions of the "Encyclopædia Britannica." His articles on colonies, educational, government, jurisprudence, law of nations, liberty of the press, and prison discipline were reprinted in a volume (1828), and are among his most effective writings. His "Elements of Political Economy" (1821–2) presented the views of Ricardo in a precise and clear style. His most elaborate work is his "Analysis of the Phenomena of the Human Mind" (2 vols. 8vo, 1829), an ingenious exposition of the sensational philosophy. His last publication was a fragment containing a severe criticism on Sir James Mackintosh's dissertation on the progress of ethical philosophy (1835).

II. John Stuart, an English philosopher, son of the preceding, born in London, May 20, 1806, died in Avignon, France, May 9, 1873. He was educated by his father in a singularly pedantic manner, and for many years subjected himself to the severest intellectual training, while pursuing a wide range of studies. In 1829 he became a clerk in the India house, in which after a series of promotions he received in 1856 the appointment of examiner of Indian correspondence, a post which had been held by his father, and which he retained till the extinction of the East India company in 1858. He was selected to edit Bentham's "Rationale of Judicial Evidence" (1827), to which he added notes and supplementary chapters. He was a frequent contributor to the journals in favor of advanced liberal views during the agitation of the reform bill. In the "London and Westminster Review," which he conducted from 1834 to 1840, appeared his masterly articles on Bentham and Coleridge, in which his aim was to interpret between their respective admirers, criticizing his own party and reporting truths which it might learn from its opponents. He also wrote for the "Edinburgh Review" and other leading periodicals. He first became widely known by the publication of his "System of Logic, Ratiocinative and Inductive" (2 vols., 1843), in which the whole character of his philosophy appears. The predominance which he gives to sensation in psychology involves the predominance of induction in logic. He denies the existence of a priori truths, affirms that knowledge is limited to phenomena, and ignores causation beyond phenomenal conditions. His "Essays on some Unsettled Questions of Political Economy" (1844) was preliminary to his second great work, entitled "Principles of Political Economy, with some of their Applications to Social Philosophy" (1848), a subject peculiarly fitted to his adroitness in the treatment of positive problems and palpable interests. He aimed, like Adam Smith, to associate the exposition of general principles with their practical applications, and also to introduce the new ideas, especially respecting currency, foreign trade, and colonization, which had been elicited by discussions subsequent to the publication of the "Wealth of Nations," to maintain a course of strict scientific reasoning while exhibiting the economical phenomena of society in their relation to the best social ideas of the present time. His "Dissertations and Discussions, Political, Philosophical, and Historical," collected chiefly from the "Edinburgh" and "Westminster" reviews (2 vols., 1859; vol. iii., 1867; vol. iv. in preparation, 1874), embrace his views on the most important topics. He maintains that scientific certainty is only relative, and that theology can have no firmer basis than an inference from the analogies of experience; that morality is but a means to an end, which is happiness, that approximation to an ideal standard of inward harmony is the method of attaining that end, that the realization of this harmony is not a moral but an aesthetic achievement, and that the utilitarian is entirely different from the selfish view of life; that poetry, music, painting, and sculpture have great social value and educative power; that political questions should be decided by the deliberately formed opinions of a select few, specially educated for the task, whose purpose should be secured by rendering them responsible to the many; that the ideal of a rational democracy is not that the people themselves govern, but that they have security for good government; that there is no essential difference between the powers of woman and man, and that she should be his partner in all actual and intellectual enterprises, and in all social and political privileges and responsibilities; and that all history is a progressive chain of causes and effects, the complex facts of each generation being caused by that which preceded it, and moulding that which follows it. He published also in 1859 a work "On Liberty," the object of which is to show that our age manifests an increasing despotism of social and political masses over the moral and intellectual freedom of individuals, that the supremacy of public opinion discourages the strength or intensity of any well-marked type of character, that energetic characters on any large scale are becoming merely traditional, and that the only guarantee against the decline of our civilization is to erect by common consent every individual human mind into an impregnable and independent fortress, within which no social authority shall have any jurisdiction. In his "Thoughts on Parliamentary Reform" (1859) he recommends the extension of the electoral suffrage to all householders without distinction of sex, on condition of improving their ability to read, write, and calculate, and a considerable extension to persons
of certain educational qualifications; advocates cumulative voting; and opposes the use of the ballot. His later works are: "Considerations on Representative Government" (1861); "Utilitarianism" (1862); "Auguste Comte and Positivism" (1865); "Examination of Sir William Hamilton's Philosophy" (1865); "England and Ireland" (1868); "The Subjection of Women" (1869); "Chapters and Speeches on the Irish Land Question" (1870); and "Autobiography" (posthumous, 1873; German translation by Karl Kolb, Stuttgart, 1874). In 1865 Mr. Mill was elected to parliament from Westminster, and acted with the advanced liberals. In 1867 he presented a petition for women suffrage, and moved an amendment to the reform bill striking out the words limiting the electorate to males. In 1868 he lost his seat.

He was chosen rector of the University of St. Andrews in 1867, and his inaugural address was published in the same year. His posthumous "Three Essays on Religion: Nature, the Utility of Religion, Theism," appeared in 1874. See "John Smart Mill: His Life and Works" (1873), 12 sketches by J. R. Fox Bourne, W. T. Thornton, Herbert Spencer, and others.

**Mill, John**, an English scholar, born at Shapp, Westmoreland, about 1645, died in Oxford, June 23, 1707. He graduated at Oxford in 1669, where, after receiving various ecclesiastical preferments, he was made in 1685 principal of St. Edmund's Hall. He became prebendary of Canterbury in 1704. His most important work is his edition of the Greek Testament, to the preparation of which he devoted the last 30 years of his life. It was undertaken at the suggestion and expense of Dr. Fell, bishop of Oxford; but after that dignitary's death Mill continued it at his own cost, and paid back to Fell's executors the money advanced. He finished the work only 14 days before his death, and it was published the same year. It adopts the received text of Robert Stephens, and contains over 30,000 various readings collected from the works of former commentators, the writings of the fathers, and ancient uncollated manuscripts.

**Millais, John Everett**, an English painter, born in Southampton, June 8, 1829. When nine years old he gained a medal from the society of arts, and was placed in Mr. Sass's preparatory school of art in London, whence at the age of 11 he was transplanted to the antique school of the royal academy. In 1843 he gained the medal for drawing from the antique. In 1846 he exhibited his first picture at the academy, "Pizarro seizing the Incas of Peru," and in 1847 obtained the gold medal for the best oil picture, his subject being "The Tribe of Benjamin seizing the Daughters of Shiloh." At this period he was induced to reject the academic rules which then prevailed, and to adopt the principles of the "Pre-Raphaelite school," of which he was one of the original members. The first picture painted by him in the new style was "Isabella," from Keats's poem, exhibited in 1849. In 1850 appeared his "Ferdinand lured by Ariel," and a mystical poem of Christ, and in 1851 "Marina in the Moated Grange," "The Return of the Dove to the Ark," and "The Woodman's Daughter." So rigorously did he follow the realistic principles involved in his new conceptions of art, that the simplicity at which he aimed was decried as an evidence of baldness and poverty, and his pictures were declared to be utterly deficient in the sense of beauty. But their unquestioned power challenged attention, and it was conceded that the naturalism which the artist sought to embody in his works was of a higher order than the literal reproduction of nature. His efforts at religious symbolism found few admirers, and were not repeated. "The Hugenot" and "Ophelia," exhibited in 1852, increased his reputation; and in the succeeding year his "Prorsibed Royalist" and "Order of Release." Some of his later works are: "A Dream of the Past: Sir Isambard at the Ford" (1857); "The Heretic" (1858); "Vale of Rest" and "Spring Flowers" (1860); "The Black Brunswicker" (1861); "My First Sermon" (1863); "Charley in my Darling" (1864); "Joan of Arc" and "The Romans leaving Britain" (1865); "Sleeping," "Waking," and "Jephthah" (1867); and "Winter Fuel" (1874). Millais was a contributor to the "Germ" (1850), a short-lived periodical, devoted to an exposition of the views of the pre-Raphaelites. He has sometimes been engaged in the illustration of books and periodicals. In 1863 he was elected a member of the royal academy, having been an associate since 1853. He married the former wife of John Ruskin, who had procured a divorce in Scotland.

**Millard, a W. county of Utah, bordering on Nevada; area, 6,090 sq. m.; pop. in 1870, 2,753. It contains Sevier lake, and is intersected by Sevier river. The W. part is mostly unexplored. The settlements are in the E. part, in the valleys along the W. base of the Wasatch mountains. Valuable minerals are supposed to exist. The chief productions in 1870 were 29,267 bushels of wheat, 6,853 of Indian corn, 9,714 of potatoes, 4,038 lbs. of wool, 23,437 of butter, 14,525 of cheese, and 900 tons of hay. There were 1,555 horses, 2,041 milch cows, 2,913 other cattle, 3,722 sheep, and 151 swine. Capital, Fillmore City.

**Millard, David**, an American clergyman, born in Ballston, N. Y., Nov. 24, 1794, died in Jackson, Mich., Aug. 3, 1873. He was brought up a farmer, but became a teacher when 17 years old. In 1815 he entered the ministry of the Christian denomination, and from 1818 to 1822 was pastor in West Bloomfield, N. Y., where he wrote "The True Messiah in Scripture Light" (1818). He also edited for several years a monthly magazine called the "Gospel Luminary." In 1837-40 he was pastor in Portsmouth, N. H. In 1841 he visited the Mediterranean and the East, and in 1848 pub-
lished "Travels in Egypt, Arabia Petraea, and the Holy Land." On his return he settled again at West Bloomfield, made frequent lecturing tours, and from 1845 to 1867 was professor of Biblical antiquities and sacred geography in the Meadville theological seminary. His life has been written by his son, the Rev. D. E. Millard (1874).

MILLAU, Milland, or Milhau, a town of Languedoc, France, in the department of Aveyron, on the Tarn, 85 m. N. E. of Toulouse; pop. in 1866, 13,683. It has a communal college and a chamber of commerce. The chief manufactures are woolen cloth, leather, gloves, and silk twist. A brisk trade is carried on in timber, cattle, wool, wine, and other agricultural products. In the religious wars of France the town became famous as one of the strongholds of the Huguenots, and in 1699 its ancient castle and the walls were demolished by Louis XIII.

MILLEDGE, John, an American soldier and statesman, born in Savannah, Ga., in 1757, died at the Sandhills, near Augusta, Feb. 9, 1818. He was one of the party which captured Gov. Wright (June 17, 1775), the first bold revolutionary act performed in Georgia. He was at the unsuccessful siege of Savannah under the count D'Estaing and Gen. Lincoln, and also at the siege of Augusta. In 1780 he was appointed attorney general, and he served frequently in the state legislature. In 1802 he was elected governor of Georgia, and served two terms. He was a representative in congress from 1792 to 1802, except one term, and United States senator from 1806 to 1809. He was the principal founder of the university of Georgia.

MILLEDGEVILLE, a town and the county seat of Baldwin co., Georgia, and formerly capital of the state, on the line of the Oconee river, at the intersection of the Macon and Augusta and the Milledgeville and Eatonton railroads, 85 m. S. E. of Atlanta, and 145 m. W. N. W. of Savannah; pop. in 1870, 2,750, of whom 1,547 were colored. It is surrounded by a beautiful and fertile cotton region, and contains several handsome residences. The governor's mansion and the state house are in good preservation, and are still the property of the state. Two weekly newspapers are published. It is the seat of the state lunatic asylum and of the state penitentiary. Milledgeville was entered by the forces of Gen. Sherman on Nov. 23, 1864, who burned the magazines, penitentiary, arsenals, depot buildings, bridges, and about 1,700 bales of cotton. The capital was removed to Atlanta in 1868.

MILLEDOLER, Philip, an American clergyman, born at Rhinebeck, N. Y., Sept. 22, 1775, died on Staten Island, Sept. 23, 1852. His father, a Swiss, came to America about 1751. The son graduated at Columbia college in 1793, studied theology, and in 1795 became pastor of the German Reformed church in Nassau street, New York, where he preached both in German and English. In May, 1800, he became one of the pastors of the collegiate Dutch Reformed church in New York, but soon after accepted the pastorate of the Pine street Presbyterian church in Philadelphia. In 1801 he was elected secretary of the board of trustees of the Presbyterian church. In 1805 he accepted a call from the then collegiate Presbyterian church in New York, with special reference to the church in Rutgers street, where he was installed on Nov. 19. In 1813 he became pastor of the collegiate Dutch church in New York. In 1825 he was appointed professor of didactic and polemic theology in the seminary at New Brunswick, N. J., and at the same time president of Rutgers college, both which offices he retained till 1855. His last residence was in New York. He published many sermons and addresses, and a "Dissertation on Inestimable Marriages" (1843).

MILLE Lacs, an E. central county of Minnesota, drained by Rum river, and containing the S. portion of Lake Mille Lacs; area, 684 sq. m.; pop. in 1870, 1,109. The surface consists of rolling prairies, with timbered bottom lands along the streams. The chief productions in 1870 were 7,920 bushels of wheat, 9,372 of Indian corn, 9,131 of oats, 5,103 of potatoes, 22,967 lbs. of butter, and 1,917 tons of hay. Value of live stock, $33,869. There were 2 saw mills and 1 flour mill. Capital, Princeton.

MILLENIUM (Lat. milline, 1,000, and annus, a year), a period of 1,000 years. In theology this term generally designates the doctrine of a return of Jesus Christ in person before the end of the world, of a first or particular resurrection of the just, who are to reign with Christ on earth, and of the destruction of Antichrist. Those who hold such views are called millenarians or chiliasts (Gr. χilioσ, a thousand). It is admitted on all sides that millenarian views were, if not general, at least very common in the ancient church. The belief was generally founded on Ps. xc. 4 and 2 Pet. iii. 8, according to which a thousand years are before the Lord as one day, compared with the account of the creation as given by Moses, the six days of creation being taken as designating 6,000 years of toil, and the subsequent sabbath 1,000 years of rest and happiness. Rev. xx. 1-6 is especially quoted by millenarians in support of their views. Millenarianism prevailed chiefly among the Jewish Christians, who retained after their conversion the hope of the Jewish nation that they would rule over all other nations under a royal Messiah. The Ebionites, the Nazareans, and the Cerinthians all strongly advocated it; and Montanus and his followers regarded it as a fundamental doctrine of the Christian religion. The early fathers of the church also declared themselves generally in favor of the doctrine: Papias, Justin, Ireneus, and Tertullian all clearly teach it; and Papias appealed in support of his view to apostolic traditions. The epistles of Clement of Rome and Ignatius of Antioch, and the epistle to Diognetus, are silent about it. Justin, though
himself a believer in the millennium, knew many orthodox Christians who were not; yet none of the apostolic fathers openly opposed it. The first opponent of whom we know was the Roman presbyter Caius, who designated the doctrine as an invention of the arch-heretic Cerinthus. Origen first gave a more rational idea of the millennium, which according to him would consist in the reign of Christian truth throughout the world, and in the voluntary submission paid to it by all secular powers. This view was upheld by the Alexandrine school. Still the old view continued to find advocates during the 3d century, among whom Tertullian, Nepos, bishop of Arsinoc, and Methodius, bishop of Tyre, were prominent. In the 4th century, though it had still many adherents among the people, it found no longer any advocate of note among the Christian writers; yet Jerome, who did not believe in it himself, did not dare to condemn it. From the 5th century millennium began to die out. It was temporarily revived, toward the close of the 10th century, by the popular belief in the approaching end of the world, and at later periods by the abbot Joachim de Floris, the Spirituals, the Apostolic Order, Peter de Oliva, and other heretics of the middle ages; but it never regained great strength. —The reformation of the 16th century gave a new impulse to millenarian views. Common opinion identified the pope with Antichrist, and regarded the expected downfall of papacy as foreshadowing the approach of the millennium. But when the Anabaptists assumed about 1584 to erect the new Zion, both the Lutheran and Reformed churches declared themselves against this caricature of the old Christian doctrine. Yet it was preached with enthusiasm by many sects and theologians of the 16th and 17th centuries, among whom were Weigel and the Moravian bishop Comenius in Germany, Jurieu in France, the Labadists in the Netherlands, and Joseph Mede and Jane Lead (died 1704) in England. —Johann Albrecht Bengel reinterpreted millenarianism into Protestant theology, where it has ever since been advocated by many prominent theologians. The ingenious prelate Oetinger (died 1782) brought it into connection with his favorite theosophic views. Hahn (founder of a Pietistic sect in Wurttemberg), Stillings, Lavater, and Hass gave it a wide circulation among the lower classes of the people in Germany and Switzerland. —With Rotte (Theologische Ethik, vol. ii.) millenarianism forms an organic link in his theosophic system. In opposition to the “spiritualism” of modern exegesis, it has been advocated, with exegetical arguments, by Hoffmann, Delitzsch, Kurtz, Hebart, and others; while Thiersch, Nitzsch, P. Lange, and Ebrard supported it from a dogmatical as well as an exegetical standpoint. Swedenborg taught that the last judgment took place in 1757, and that the New church or church of the New Jerusalem had actually been formed both in heaven and on earth. After Germany, England and America have been the chief fields of modern chiliasm. The “Catholic Apostolic Church,” organized by Edward Irving, laid great stress on the belief that the kingdom of glory was very near. Millenarian views lie at the foundation of Mormonism, the people who hold that belief calling themselves “Latter Day Saints” in reference to the near approach of the last day. The sect commonly called Shakers style themselves the “Millennial Church.” In the United States a great agitation was called forth by the preaching of William Miller, who sought to prove from the Scriptures that the second advent of Christ would occur about 1843. He not only found numerous believers in most denominations, but also occasioned the organization of a new denomination of Adventists. One of the most noted of recent millenarians is the Englishman Dr. John Cumming, who placed the end of the “present dispensation” in 1866 or 1867, and then in 1868. In November, 1870, he published “The Seventh Vial,” to prove that all the prophecies concerning the millennium have been fulfilled.—Millenarian views in various periods of the Christian church differ widely respecting most points, except the duration of the millennium, which nearly all of them fix at 1,000 years. The beginning of the millennium was fixed by Hippolytus at the year 500, by Jurieu at 1785, by Bengel at 1836, and by others at other dates. Many agree in expecting it between 1879 and 1887. Commonly the earth is believed to be the only place of the millennium, and Jerusalem its central point of union. Many still hold the view of Origen (see above), and of Martensen (Christliche Dogmatik, 1850), that it denotes the period of highest earthly prosperity of the church in the spiritual return of Christ to the earth.—A good history of millenarianism in the Christian church is still a desideratum, as the works published do not exhaust the subject. See Corrodi, Kritische Geschichte des Chiliasmus (Frankfort, 1781); and D. T. Taylor, “The Voice of the Church on the Coming and Kingdom of the Redeemer: A History of the Doctrine of the Reign of Christ upon Earth,” revised by Iastings (2d ed., Peacedale, R. I., 1865).

MILLEPEDE. See CENTIPEDE.

MILLEPORE (millepora, Linn.), a genus of hydroid meduse. The animals live in communities, which take on various arboreal and incurve shapes; they deposit much carbonate of lime in their tissues, so that the medusa stock is in outward appearance almost solid, with minute pores on the surface which contain the animals. A cross section of this stony skeleton shows that the minute individuals of the community constantly grow outward in the direction of their longitudinal axis, forming as they proceed long calcareous tubes, which are so intimately cemented together as to make a compact mass. Across these tubes, at short intervals, are formed little transverse
platforms, which divide the tubes into joints or cells. These platforms are deposited by the base of the animal, and are of high importance in classification; by them is characterized Milne-Edwards's division of the tabulata, which includes millepora. Till within a short time all zoologists have placed the millepores among polyps. In the winter of 1857-'8 Prof. Agassiz succeeded, for the first time, in observing the animals of millepora alecornis in Florida, and was surprised to find them not polyps, but true hydroid medusae, resembling hydractinia. This observation gives great importance to the medusa, as represented among the fossils, for the tabulata are found abundantly as low as the Silurian formations. As the presence of mesenteric septa seems to militate against the above mentioned separation, some naturalists retain them among the polyps.—See "The British Fossil Corals," by Milne-Edwards, in the "Transactions of the Palaeontographical Society;" Dana's "Zoophytes" and "Corals and Coral Islands," the "American Journal of Science," vol. xxvi., p. 140 (1858); and Agassiz's "Contributions to the Natural History of the United States," vol. iii.

MILLER. I. A S. W. county of Georgia, intersected by Spring creek, a branch of Flint river; area, about 250 sq. m.; pop. in 1870, 3,091, of whom 956 were colored. The surface is level, and the soil moderately fertile. The chief productions in 1870 were 91,918 bushels of wheat, 256,141 of Indian corn, 69,977 of oats, 12,475 of potatoes, 10,436 lbs. of tobacco, 22,482 of wool, 31,773 of butter, and 1,567 bales of cotton. There were 2,926 horses, 2,474 milch cows, 4,271 other cattle, 11,504 sheep, and 17,841 swine. Capital, Tuscumbia.

MILLER, Bénigne Emmanuel Clément, a French philologist, born in Paris in 1812. In 1834 he received an appointment in the manuscript department of the royal library, where he became thoroughly acquainted with Greek paleography. In 1835 and 1836 he was sent to the libraries of Italy and Spain to collect the scholia of Aristophanes. Among the results of his explorations were a Supplément aux dernières éditions des petits géographes grecs (8vo, 1839), Catalogue des manuscrits grecs de la bibliothèque de l'Escorial (4to, 1845), and Poésies grecques inédites de Manuel Philé. In 1851 he published at Oxford, under the title of Philosophumena, sive omnium Harresium Refutatio, the text of a manuscript procured from Mt. Athos by Mynas, which he believed to be an original treatise of Origen, but which is now generally attributed to Hippolytus. In 1840-'46 he published Revue de bibliographie analytique (6 vols.), which met with moderate success; and he has edited several minor Greek authors. He was also one of the principal editors of the Recueil d'itinéraires anciens (4to, with atlas, 1844). In 1849 he became librarian of the national assembly, and in 1860 was elected to the academy of inscriptions and belles-lettres. One of his latest works is Mélanges de littérature grecque (8vo, 1868).

MILLER, Edward, an American physician, born in Dover, Del., May 9, 1760, died in New York, March 17, 1812. He attended medical lectures in the university of Pennsylvania, spent about a year in the military hospital at Baskingridge, N. J., and in 1782 went to France as the surgeon of an armed ship. In 1786 he entered on the practice of medicine in Maryland, and in 1788 graduated as M. D. in the university of Pennsylvania. In 1796 he removed to New York, and with Dr. Mitchell and Dr. Smith commenced the publication of the "Medical Repository," the first American medical journal. In 1803 he was appointed resident physician for the city of New York. He was a member of the American philosophical society, professor of the theory and practice of physic in the college of physicians and surgeons, and one of the physicians of the New York hospital. His "Report on the Yellow Fever of New York in 1805" is the source from which most later authors have drawn their arguments in support of the non-contagious nature of yellow fever. His writings, with a biographical sketch, were published by his brother, the Rev. Samuel Miller (8vo, 1814).

MILLER, Hugh, a British geologist, born at Cromarty, on the E. coast of Scotland, Oct. 10, 1802, died at Portobello, near Edinburgh, Dec. 26, 1856. He belonged to that half Scandina-
vian population inhabiting the shores of the German ocean from Fife to Caithness. On his father's side he was fourth in descent in a line of sailors from John Feddes, one of the last of the buccaneers on the Spanish main, who returned to Cromarty to enjoy his money, and built "the long, low house" in which his distinguished great-grandson passed his youth. On his mother's side he was of highland blood, and fifth in descent from Donald Roy of Ross-shire, famed for his piety and his second sight. His father was drowned in a tempest (a fate which had befallen several of his ancestors) in 1807; and from that time, though still living with his mother, he was chiefly under the care of two maternal uncles, who had greater influence and authority over him until the age of manhood than any other persons. One was a harness maker and the other a cartwright, and he accounts them the most important of his schoolmasters. His uncle Alexander encouraged his early bent toward natural history, and taught him much about rocks, clouds, rains, tides, trees, ferns, shell fish, sea fowl, and insects. His uncle James interested him in human history, and gave him his liking for traditional lore, Scottish antiquities, social habits, and individual eccentricities. The tastes and predilections of both uncles were deeply impressed on him, and wherever he went in later life the geology and humanity of the district seemed equally to attract him. In his fifth year he was sent to a dame's school, where he learned to read. He was thence transferred to the grammar school of Cromarty, where he went through the ordinary course of rudimentary studies. He even began Latin with a view to college, but from distaste failed in it completely, being usually at the nether end of a very poor class, which position even he maintained only by displaying an unaccountable facility in translation. The master read aloud every morning in English the task assigned for the day, and Hugh was able to remember the whole rendering in its order, and to give it back in the evening word for word. Much of the leisure secured in this way was employed in reading translations from the classics by stealth. About his 15th year he attended for some time a subscription school set up as a rival to the grammar school. But from this whole amount of pedagogy he derived, according to his own estimate, only one advantage, namely, the faculty of reading books, with the correlative accomplishment of writing. He had acquired a reputation among his class fellows as a narrator of stories; and having exhausted the subjects of his reading and the various adventures that he had himself heard told, he was accustomed to extemporize with great success the wildest biographies. Meantime, other branches of his education had been going on outside of the school. He was the leader in excursions along the precipices and into the caves on the coast. He had learned to collect on the beach and to distinguish from each other the various rocks of the locality, as porphyries, granites, gneisses, quartz, and mica schists, and had discovered for himself that Cromarty possessed among its minerals one precious stone, the garnet; and his observations in other departments had been encouraged and corrected by his uncle Sandy, who, as he always claimed, knew more of living nature than many professors of natural history. He had studied scenery, customs, and physiognomies in the highlands of Sutherlandshire, among his Gaelic cousins; had heard the story of Colloiden from men who fought in the battle; had conversed with an old lady who witnessed the last witch-burning in the north of Scotland; and had acquired a habit, which marks his life and his writings, of studying historical monuments as well as geological formations, collecting local legends as well as fossils, delighting as much to discover a kelpie as a pterodactyl, and regarding types of character and phases of society in connection with the facts of science. The foremost youth in the district, his uncles wished him to prepare for Aberdeen college and to study for the church; but he demurred, declaring that he had no call to the sacred office, and they admitted that he had better be anything than an unceiled minister. A trade was therefore resolved upon, and he was apprenticed for three years to one of his relatives, who was a stone mason. From his 17th till his 34th year he led the life of an operative mason, journeying in summer to pursue his labors in different parts of Scotland, devoting all his leisure to earnest intellectual cultivation, reading all kinds of books on summer evenings and at home during the winter, and cherishing a belief from the beginning that literature and perhaps natural science would after all prove his proper vocation. During the first part of this period (1818-25), as an apprentice and journeyman, he was subjected to all the coarse and rough experiences of his trade, working as one of a gang in quarries or in sheds, and passing his evenings in wretched highland bothies or in hovels in lowland villages. He afterward exchanged the life of a journeyman, working season after season for different masters, for that of a jobbing mason, undertaking private commissions in the way of his trade, such as the sculpturing and lettering of tombstones, stone dials, and the like; yet his habits of work continued in all respects to be those of a common mason, and his domestic accommodations those of any frugal Scotch mechanic. During this laborious period of his life he formed an intimate and extensive acquaintance with the best English and Scotch literature, embracing not only the departments of fiction, history, and poetry, but the philosophical works of Locke, Kames, Hume, Reid, Adam Smith, and Dugald Stewart. He seized upon every work of natural science that fell in his way, and moreover wrote a great variety of verses, rhapsodies, and reflections. His various scenes of labor made him familiar with the scenery, antiquities, and
HUGH MILLER

social peculiarities of different parts of Scotland. But his greatest progress was in geology. Starting with hardly more than an empirical knowledge of the mineral characters of rocks, he soon detected the wonders of the fossil world in quarries remarkably rich in organisms. Wherever he went, from the shores of the Morny frith to those of the frith of Forth, the hammer was in his pocket, and his eye was searching for fossil specimens. Combining what he saw with what he read, he became, while yet hardly aware of it, not only a self-taught geologist, but a geologist capable of teaching others. To this period belong his discoveries in the old red sandstone, which only required to be known to insure him distinction in the scientific world. In 1825, work falling in the north, he sailed for the south of Scotland, and went from Leith to the capital. There he was occupied for two years, till his health began to fail, and he learned that few Edinburgh stonecutters pass their 40th year, and not one in 50 reaches his 45th. He therefore returned to Cromarty, accustomed to contemplate with rather pensive than sad feelings an early death, and soon after became seriously interested in the personal bearing of religious concerns. Until this time he describes himself as wavering between two extremes, now a believer and anon a skeptic, the belief being instinctive, the skepticism arising from some intellectual process. The result of his thoughts and conversations was that he found rest in the fundamental principles of Scottish evangelism. His attainments soon made him a local celebrity; geologists in other towns corresponded with him; Cromarty ladies began to walk up to where he was at work to have the pleasure of conversing with him, one of whom was the young lady who afterward became his wife; and he was elected town councillor. He published a volume of "Poems written in the Leisure Hours of a Journeyman Mason" (1829); contributed a series of letters to the "Inverness Courier" on the herring fishery, which were collected in a volume; discovered deposits of ichthyic remains belonging to the second age of vertebrate existence, sufficient to prove not only the existence but the structure and varieties of fishes at that early period; and at length exchanged manual labor for the office of accountant in a branch bank opened at Cromarty. During the first two years of his accountantship his marriage took place, his "Scenes and Legends of the North of Scotland" was published, and he became a frequent contributor to periodicals. The non-intrusion controversy was then at its height in the Scottish church, and immediately after the adverse decision of the house of lords in the Auchterarder case he published his celebrated "Letter to Lord Brougham," which, as Mr. Gladstone affirmed, showed a mastery of pure, elegant, and masculine English that even an Oxford scholar might have envied. The leaders of the Free church were then look-

ing for a man to edit their contemplated organ, and at once selected Mr. Miller, who in 1840 removed to Edinburgh as editor of the "Witness." As a Scottish journalist he held a high and almost unique place. His leading articles were essays remarkable for their deliberate thought, elevated moral tone, strong Presbyterian feeling, and fine literary finish, and exerted a powerful influence on the formation of public opinion. His genius for description, literary culture, and relih for peculiar social characteristics appear also in his account of a vacation tour, entitled "First Impressions of England and its People." But his greatest eminence was achieved in the department of practical and speculative geology. He went to Edinburgh with the results of many years of scientific observation and reflection, with a collection of boulders, fossil fishes, and other objects of natural history, and with a collection of thoughts and speculations about them, which in his own judgment formed his most valuable capital. During the first year of his editorship he published in the "Witness" a series of papers, afterward known collectively under the title of "The Old Red Sandstone, or New Walks in an Old Field," in which he detailed the story of his researches and revealed his discoveries of fossils in a formation which had till that time been deemed almost destitute of them. These were immediately recognized by savants as important additions to geological science. At the meeting of the British association in 1840 his labors were the principal theme; the fossils which he had picked up in boyhood in his native district were promoted to their due rank as "Sterichthyas Milleri;" and Murchison and Buckland spoke of his descriptive talent as casting plain geologists like themselves into the shade, and making them ashamed of their meagre style. His severe tasks endangered his health and compelled him to forego all literary labor during the greater part of 1845 and 1846; but he returned from his seclusion only to be more intimately associated with Dr. Chalmers in the counsels of the Free church. The appearance and popularity of the "Vestiges of the Natural History of Creation," embodying the development theory, and aiming to transfer the work of creation from the realm of miracle to that of natural law, caused him to prepare a reply, entitled "The Footprints of the Creator, or the Asterolepis of Stromness," an able and strongly fortified exposition of the opposite view, which had a very wide circulation in England and America. One of his most interesting works is "My Schools and Schoolmasters, or the Story of my Education," a full review of his life until the time of his settlement in Edinburgh. He published in 1848 the "Geology of the Bass Rock," lectured on geological subjects in Edinburgh and London, read papers before the British association, and had just completed at the time of his death his "Testimony of the Rocks," in which he dis-
cusses the Biblical bearings of geology. He toiled upon this task night and day, with little sleep or exercise, until, after a week or two of cerebral disorder, he himself became conscious that his mind was on the verge of ruin. He felt occasionally as if a very fine poignard had been suddenly passed through and through his brain, and in some of his paroxysms his face was a picture of horror before which even his wife shrank in dismay. He was found lifeless in his study, his chest pierced with the ball of a revolver which was found lying close by.

In a pathetic note left for his wife he had written: "A fearful dream rises upon me. I cannot bear the horrible thought." His principal works have been republished in America.

MILLER, James, an American general, born in Peterborough, N. H., April 25, 1776, died in Temple, N. H., July 7, 1851. He was educated for the bar, but in 1808 entered the army as major. In May, 1813, he participated in the capture of Fort George. As colonel of the 21st infantry he fought with gallantry at Chippewa and Lundy's Lane. The success of the Americans in the latter conflict was mainly due to the capture of a British battery by his command. In reply to Gen. Scott's inquiry if he could take the battery, he said, "I'll try, sir." For these services he was brevetted brigadier general, and received from congress a gold medal. He was governor of Arkansas territory from 1819 to 1823, and collector of customs at Salem, Mass., from 1823 to 1849.

MILLER, James, a Scottish surgeon, born in 1812, died June 17, 1864. He was professor of surgery in the university of Edinburgh for more than 20 years, and at the time of his death of pictorial anatomy to the royal academy and consulting surgeon to the royal infirmary of Edinburgh and the royal hospital for sick children. He is especially noted for his systematic treatise on the "Principles and Practice of Surgery" (Edinburgh, 1844), which passed through four editions and is highly esteemed.

MILLER, Joaquin, an American poet, whose real name is Cincinnatus Ilmer Miller, born in Indiana, Nov. 10, 1841. When he was about 11 years old his father emigrated to Lane county, Oregon, whence the boy went three years later to try his fortune in California. He wrote verses even then, although he knew nothing of the laws of versification nor of the rules of grammar. After a wandering life of several years, he returned home in 1860, and entered a lawyer's office in Eugene, Oregon. The next year he was an express messenger in the gold-mining districts of Idaho, which he left to take charge of the "Democratic Register," a weekly newspaper in Eugene. This was suppressed for its political sentiments during the war, and in 1863 he opened a law office in Cañon City, Oregon. From 1866 to 1870 he served as county judge of Grant county, and during this time began to write his poems. He published first a collection in paper covers called "Specimens," and next a volume with the title "Joaquin et al.," from which he derived his pseudonym. In 1870 his wife, whom he had married in 1868, obtained a divorce, and he went to London, where he published in the following year his "Songs of the Sierras." In 1872 appeared "Songs of the Sun Lands," and in 1876 a prose volume entitled "Life among the Modoces: Unwritten History."—His wife, Minnie Theresa (Dyer) Miller, has also published verses, under the pseudonym of "Minnie Myrtle."

MILLER, Joseph, an English actor, born probably in London in 1684, died there in 1738. He was popular on the stage, and performed with repute in several of Congreve's best comedies, particularly in "Love for Love" and "The Old Bachelor," to the success of which he is said to have materially contributed. In 1733 he published a book of jests passing under his name, and supposed to be by the collaboration of John Motteley, author of a life of Peter the Great, was published in London, and has gained a celebrity which preserves the name of its assumed author.

MILLER, Samuel, an American clergyman, born near Dover, Del., Oct. 31, 1769, died in Princeton, N. J., Jan. 7, 1850. He graduated at the university of Pennsylvania in 1789 (from which he received the degree of D. D. in 1804), studied theology, was licensed to preach in 1791, and in June, 1793, was installed as colleague pastor with Drs. Rodgers and McKnight of the first Presbyterian church in New York city. In 1813 he became professor of ecclesiastical history and church government in the theological seminary at Princeton, and discharged the duties of this office till May, 1849, when he resigned. Dr. Miller was a devoted friend of the Presbyterian church, and enlisted vigorously in the controversy which resulted in its division. He was the author of "A Brief Retrospect of the Eighteenth Century" (2 vols., New York, 1803; 3 vols., London, 1805); "Letters on the Constitution and Order of the Christian Ministry" (1807), with a "Continuation" (1809); "Memoirs of the Rev. John Rodgers, D. D." (1818); "Letters on Unitarianism" (Trenton, 1821); "Letters on Clerical Manners and Habits" (Philadelphia, 1827); "An Essay on the Office of Ruling Elder" (New York, 1831); "Letters to Presbyterianans" (1833); "Discourses on Infant Baptism" (1834); "Presbyterianism the truly Primitive and Apostolical Constitution of the Church of Christ" (Philadelphia, 1835); "The Primitive and Apostolic Order of Christ vindicated" (1840); "Letters from a Father to his Sons in College" (1843); "A Sermon on the Ruling Eldership, with an Appendix" (1843); and "Thoughts on Public Prayer" (1849). He also wrote the "Life of Jonathan

MILLER, Thomas, an English author, born in Gainsborough, Lincolnshire, Aug. 31, 1807, died in London, Oct. 28, 1874. He was at first a farmer's boy, devoted his leisure hours to study, and while following the trade of a basket maker began to attract attention by his verses and occasional pieces in prose, chiefly describing rural life and scenery. He came under the notice of Moore, Campbell, and Rogers, and the last named enabled him to set up as a bookseller, and thenceforth he became an industrious writer. Among his numerous novels are "Royston Gower" (1838), "Fair Rosamond" (1869), "Lady Jane Grey" (1840), "Gideon Giles the Roper" (1841), and "Godfrey Malvern" (1842). The most popular of his writings are his country books, including "A Day in the Woods," "Foraging in the Country," "Rural Sketches," "Pictures of Country Life," "Country Scenes," &c. He also wrote a "History of the Anglo-Saxons," and lives of Turner, Beattie, and Collins. His poetical works are: "Common Wayside Flowers" (1841); "Poetical Language of Flowers" (1847); "Original Poems for my Children" (1850); and "Songs for British Riflemen" (1860).

MILLER, William, an American religiousist, born in Pittsfield, Mass., in 1781, died in Low Hampton, Washington co., N. Y., Dec. 20, 1849. In the war of 1812 he was captain of a company organized to protect the northern frontier. He was a farmer, whose early facilities for education were slight, and he seems never to have been master of what are usually deemed the requisite resources for Biblical criticism; but in 1833 he began to lecture on the speedy second coming of Christ, announcing, in accordance with his interpretation of the prophecies, that the earth was to be destroyed in 1843. Even the day was specified, if not by himself, by some of his principal followers. His earnest and confident manner attracted attention, his Scriptural and historical arguments seemed to many erudite and cogent, and after a few years of constant travel and preaching his disciples were reckoned at from 30,000 to 50,000. (See Second Adventists.)

MILLER, William Allen, an English chemist, born in Ipswich, Dec. 17, 1817, died in Liverpool, Sept. 20, 1870. At 15 years of age he was apprenticed to his uncle, who was surgeon to the general hospital in Birmingham. At the expiration of five years he entered the medical department of King's college, London, where he studied chemistry under Dr. Daniell, whom he assisted in his laboratory. In 1840 he passed some time in the laboratory of Liebig in Giessen, became demonstrator of chemistry in King's college, and in 1845 professor of chemistry. With Dr. Daniell he had investigated the electrolysis of salts, conducting all the experiments. In 1851 he was appointed a commissioner on the water supply of London, and an assayer of the mint. He was the author of an important treatise entitled "Elements of Chemistry, Theoretical and Practical" (London, 1869), and of numerous scientific papers.

MILLET, a name given to grasses of several distinct species and genera; it is from the Italian milletto, diminutive of miglio, from the Latin milium, which in turn is supposed to be from mille, a thousand, in reference to its fertility. The present botanical genus milium does not include either of the plants known to agriculture as millet, but is a small genus in the tribe of panicceae, the principal species in which, M. effusum, is very widely diffused; this, which is known as millet grass and spreading millet, grows all over Europe and northern Asia, extending from the Mediterranean to the Arctic circle, and in this country from New England to Illinois and northward; it is generally found in cool and damp woods. It is a slender grass, sometimes 4 or 6 ft. high, with broad, flat, thin leaves and a spreading panicle; the spikelets, by the suppression of one of the glumes, appear as if one-flowered. This grass is not regarded as of any agricultural value, but in England its growth is encouraged in woods on account of the great fondness of pheasants for its abundant seeds.

What is known as the double-seeded or double-bearing millet grass was formerly placed in this genus, but is now called amphiocarpum, a name given upon the supposition that it was doubly fruit-bearing; it has panicles like other grasses, but the spikelets (or flowers), though perfect, drop without shedding their maturing seeds; at the base of the plant another set of flowers is produced; these are solitary at the end of slender runner-like stalks, and are fertilized and perfect their fruit wholly underground. This plant is found abundantly in New Jersey, and since the cranberry has been so largely cultivated in that state it has attracted much attention, and was at one time regarded as a dangerous enemy to the culture; after the bogs have been prepared and planted with cranberries, this double-seeded millet grass makes its appearance in the greatest profusion, and apparently threatens destruction to the plants; but it is found that it does no great injury, and that the cranberry plants soon take possession of the soil to the exclusion of the grass. This species is A. Purshii, and extends southward to Georgia. Another and much more rigid species is A. Floridanum, very local in Florida.—The true millet of an-
Millet and modern agriculture is *paniceum milaceum.* The genus *panicum* (the ancient name for a grass which is now placed in another genus) is a very extensive one, about 850 species being enumerated; yet but few of them are ranked among the useful grasses, and millet is one of the few that furnish food; this has been so long in cultivation that the history of its origin is very obscure. It has a strong stem, 2 to 4 ft. high, with a profusion of foliage; its abundant flowers are in large, open, nodding panicles, and the plant has much the appearance of a miniature broom corn; the seeds afford a very nutritious flour. The plant requires a dry rich soil, and when now cultivated it is usually for forage, to be cut and cured like grass before the seeds are ripe enough to drop. The ease with which our farmers can raise crops of fodder corn (maize) precludes the growing of this and other forage crops which are valued in Europe. Hungarian, German, and Italian millets are varieties of *setaria Italica.* The genus *setaria* is regarded by some botanists as a section of *panicum,* the only difference between them being that in *setaria* the short pedicels of the flowers are prolonged beyond them into bristles, which in the millet species are in clusters of two or three and longer or shorter than the flowers. In this as in most other setarias the spikelets or flowers are collected in a very dense spike-like panicle, which in some forms is a foot or more long and usually interrupted at the base. None of these millets are cultivated in this country for their seeds, unless occasionally for feeding poultry, but they have obtained in some localities a place as forage plants. The most useful is the Hungarian millet, more generally called Hungarian grass (*S. Italica* var. *Germanica*), which is excellent to supplement a short hay crop; it is an annual, of very rapid growth, and on rich soils gives a very large amount of green fodder, or it may be made into hay. If to be cured, it should be cut as soon as it blooms, and before the numerous small bristles of the flowers become firm, as these when ripe and rigid may prove injurious to horses. This *setaria* is a most variable species, and every few years a new form of it is introduced with a new name, which does not prove essentially different from the old. Other species of *setaria* are known as fox-tail and bottle grasses; they are common in cultivated grounds as weeds. Long before *sorghum* was cultivated in this country as a sugar plant, a variety of it was grown as Indian millet. (See Sorghum.)

**Millet, Almé,** a French sculptor, born in Paris about 1816. He studied under David d'Angers, and became famous in 1837 by his "Ariadne," which was purchased by the government. The most celebrated of his recent works are a statue on the tomb of Henri Murger, "Apollo" in the grand opera house, the monument of Baudin in Père Lachaise, and a statue of a garde mobile for Léon Dupré's monument to the guards of the department of Eure who fell in the war of 1870–71.

**Millet, Jean François,** a French painter, born about 1815, died Jan. 18, 1875. He studied under Delaroché, and was distinguished for his genre pictures and landscapes, which represent rural life according to the realistic school with remarkable fidelity. Among his finest works are "A Girl shearing Sheep" (1861), which was again exhibited with other works in 1867; "Teaching Tricot" (1869); "November," and "A Woman making Butter" (1870).

**Millet, Pierre,** a French missionary, born in 1681, died in Quebec, March 22, 1708. He came to America in 1666, and was soon after sent to Onondaga, laboring there and at Oneida till 1684, and making a few converts. He returned to Oneida in 1888, but because of the English influence could not restore his mission. While acting as chaplain at Fort Frontenac in 1690, he was lured out by the Indians and taken prisoner. The Christian Onedas in the large Iroquois force claimed him, and he was sent to their canton, and finally adopted into the tribe. The New York authorities who had been hostile to him now endeavored to induce the Oneidas to give him up; but they refused, and he remained there till October, 1694, to the great annoyance of New York, the governors of that colony endeavoring to effect his release, and the governors of Canada to prevent it. His own account of his captivity was published at New York in 1855.

**Millin, Anbün Louis,** a French archaeologist, born in Paris, July 19, 1759, died Aug. 14, 1818. He was keeper of the museum of antiquities in the national library. His principal works are: *Peintures des vases antiques; Monuments antiques inédits; Galerie mythologique; Voyage dans les départements du midi de la France; and Histoire métallique de la révolution française.* His "Medallic History of Napoleon," left incomplete, was published in English by J. Millingen (London, 1819). He was the founder of the *Magasin encyclopédique* and *Annales encyclopédiques.*

**MILLOT, Claude François Xavier,** a French ecclesiastic, born at Ornans, Franche-Comté, March 5, 1726, died in Paris, March 21, 1785. He entered the society of Jesus, and became professor of rhetoric at their college in Lyons; but his relation with them was brought to a close by their objections against his eulogy of

Hungarian Millet (*Setaria germanica*).
Mills, Samuel John, Jr., an American clergyman, born in Torrington, Conn., April 21, 1783, died at sea in June, 1818. His father was a Congregational minister. He entered Williams college in 1806. In September, 1808, a society was formed in the college "to effect, in the persons of its members, a mission or missions to the heathen;" and the first name appended to its constitution was that of Mr. Mills. This was the first foreign missionary organization in America. He graduated in 1809, spent some months at Yale college, and in the spring of 1810 entered Andover theological seminary, where he found others interested in the subject; and on June 28, in connection with Messrs. Judson, Nott, and Newell, he presented a memorial to the general association of Massachusetts, stating their views and wishes, and asking advice. This led directly to the formation of the American board of commissioners for foreign missions. In 1812, soon after he was licensed, he went on a missionary tour to the southwestern states, under the combined patronage of the Connecticut and Massachusetts missionary societies. On this tour he preached and organized Bible and other religious benevolent societies. In July, 1814, he made a second tour to the same region, accompanied by the Rev. Daniel Smith. He published an account of these two trips on his return (Andover, 1815). He was ordained June 21, 1818, and passed most of the next two years in Albany, New York, Philadelphia, and Washington. Among the fruits of these two years' labor may be named the establishment of the foreign mission school at Cornwall, Conn., the organization of the American Bible society and of the united foreign missionary society, afterward merged in the American board, the first movement for city missions in New York, the establishment of a school for the education of colored preachers and teachers at Parsippany, N. J., by the aid of New York and New Jersey, and the organization of the American colonization society. Almost immediately after its organization, the colonization society sent Mr. Mills and the Rev. Ebenezer Burgess to Africa, to select a site for a colony. In February, 1818, they embarked at London for the African coast, where they spent two months. Having fulfilled the object of their mission, they sailed on their return, May 22, 1818, and Mr. Mills died before reaching home.

MILLSTONE, a hard and rough stone in one or many pieces, formed into cylindrical shape, from 3 to 7 ft. in diameter, and 8 to 18 in. thick, used together with another of the same

Mires. He then devoted himself to the preparation of historical works for schools, which obtained for him in 1768 the chair of history at the college of nobles in Parma. In 1777 he became a member of the French academy, and in 1778 preceptor of the duke d'Engliren. His works on French, English, and general history were published under the title of Euvres de l'abbé Millet (15 vols., 1800; 2d ed., 12 vols. 8vo, 1819).

MILLS. 1. A S. W. county of Iowa, bordering on Nebraska, from which it is separated by the Missouri river, and drained by the Nishnabatawa river and branches; area, about 400 sq. m.; pop. in 1870, 8,718. It is intersected by the Burlington and Missouri River, and the Kansas City, St. Joseph, and Council Bluffs railroads. The chief productions in 1870 were 162,901 bushels of wheat, 1,380,055 of Indian corn, 191,569 of oats, 80,074 of potatoes, 11,652 lbs. of wool, 132,755 of butter, and 16,471 tons of hay. There were 4,122 horses, 3,688 milch cows, 6,816 other cattle, 3,354 sheep, and 13,985 swine; 3 manufactories of brick, 2 of brick and stone, 4 saw mills, and 5 flour mills. Capital, Glenwood.

2. A S. E. central county of Dakota, recently formed, and not included in the census of 1870; area, about 1,000 sq. m. It is intersected by the Dakota river and several of its affluents. The surface is rolling, and consists mostly of prairies.

Mills, Charles, an English historian, born at Greenwich, July 29, 1788, died in London, Oct. 19, 1825. He studied law, but abandoned it for literary pursuits. His principal works are: "History of Mohammedanism" (8vo, London, 1817); "History of the Crusades" (2 vols. 8vo, 1820); and "History of Chivalry" (2 vols. 8vo, 1825).

Mills, Clark, an American sculptor, born in Onondaga co., N. Y., Dec. 1, 1815. He lost his parents in childhood, and learned the trade of a plasterer, which he followed in Charleston, S. C., for nine years. He early manifested a taste for sculpture, and in 1846 made a marble bust of John C. Calhoun, which was purchased for the city hall of Charleston. In 1848 he was invited to furnish a design for an equestrian statue of Jackson, for Lafayette square, Washington. His design was accepted, and he finished, after two years' labor, a full-sized model in plaster, which was so balanced that it rested on the horse's hind feet alone, without other support. Mills had now to build a foundery and to learn the practical business of casting, for there was no establishment large enough for the purpose, and no workman in the country capable of casting so large a mass. After numerous trials, interrupted by unforeseen accidents, he produced a perfect cast in October, 1853, and the statue was set up in 1853, on Jan. 8, the anniversary of the battle of New Orleans. It was completed at a loss to him of $7,000, but congress made him an appropriation of $20,000. At the same ses-
size and shape for grinding grain, &c. The lower stone is firmly fixed in its bed, and is known as the "bedder." The upper one, called the "runner," is suspended over this so as to revolve with its lower face exactly parallel to the upper face of the lower stone, and more or less close to it according to the required fineness of the flour. The grain is admitted through a hole in the centre of the upper stone from the hopper above; and as it is ground the flour escapes round the outer edges. Grooves are cut on the face of each stone, radiating from near the centre to the periphery, and one edge of these grooves is sharp and perpendicular to the face. The two stones being cut alike, when they are turned face to face these edges work against each other and crush the grain between them. The flat portions each side of the grooves are called "lands." The best millstones are made of buhlstone. (See Buhlstone.) They continue in use sometimes as long as 20 years, the edges being occasionally recut. Very hard granite is also used for millstones, and the Shawangunk sandstone has long been quarried at Esopus, N. Y., for the same purpose.

**MILLSTONE GRIT** is a geological formation, principally a conglomerate, composed of silicious sand and small pebbles; it is also called grit rock and grindstone grit. It is named from the frequent use to which it is put, particularly in England. The formation lies at the commencement of the coal period, being located between the subcarboniferous period and the lower coal measures, and marks the transition from the marine to the terrestrial period. The area that had been covered with fields of crinoids was swept during the millstone grit epoch by currents and waves which left the surface under a great depth of pebbles and sand. The coarseness of the beds along the Appalachian region in Pennsylvania indicates that this was the border reef of the continent, and its great thickness, exceeding 1,200 ft., shows that it was also a region of great subsidence. The formation here is mostly a whitish silicious conglomerate, with some sandstone layers and a few thin beds of carbonaceous shales. At Tamaqua the thickness is 1,400 ft.; at Pottsville, 1,000 ft.; in the Wilkesbarre region, from 200 to 300 ft.; and where it caps the mountain at Blosburg it is from 50 to 100 ft. In Virginia the thickness sometimes reaches 1,000 ft., and the rock is mainly a sandstone, but contains heavy beds of conglomerate. It may be remarked that the conglomerate of the subcarboniferous period becomes also in Virginia a sand rock. In Alabama it is a quartzose grit of great thickness, and is used for millstones. In Tennessee there are two heavy beds of conglomerate, with several thick coal beds between them, and also below both, which are generally referred to the false coal measures of the millstone grit epoch. The millstone grit formation extends over parts of some of the southern counties of New York, having a thickness of from 20 to 60 ft. In Cattaraugus and Allegany counties, on account of the regularity of the joints, it stands out in huge blocks, forming walls and square structures which have received the names of "Rock City" and "Ruin City." Among the plants of this formation, according to Lesquieres, are lepidodendrons, sigillarias, and calamites, with several species of ferns.

**MILLVILLE**, a city of Cumberland co., New Jersey, on Maurice river, at the head of navigation, and on the West Jersey railroad, 49 m. S. of Philadelphia; pop. in 1870, 6,101. It contains a large cotton factory, and three iron foundries for the manufacture of water and gas pipes and turbine water wheels. The immense wheels for the Fairmount water works, Philadelphia, were cast here. It has also several manufactories of hollow glassware and window glass, three large lumber mills, a national bank, 11 public schools, including a high school, two weekly newspapers, and nine churches.

**MILMAN, Henry Hart,** an English author, born in London, Feb. 10, 1791, died there, Sept. 24, 1868. He was the youngest son of Sir Francis Milman, physician to George III., and was educated at Éton and at Brasenose college, Oxford, where he obtained a fellowship. His literary career commenced in 1815, with the publication of "Fazio," a tragedy performed successfully at Covent Garden; and in 1817 he took orders and was presented to the vicarage of St. Mary's, Reading. In 1818 he published "Samor, Lord of the Bright City, an Heroic Poem," founded on passages in the legendary history of Britain, and in 1820 his most successful production in verse, "The Fall of Jerusalem," a dramatic poem. In the succeeding year he was appointed professor of poetry in the university of Oxford, and published three other dramatic poems, "The Martyr of Antioch," "Belshazzar," and "Anne Boleyn." In 1826 he was appointed Bampton lecturer, and in the following year appeared his "Sermons at the Bampton Lecture," in 1829 his "History of the Jews" (3 vols. 8vo), published anonymously, and in 1840 a collected edition of his poetical works. In the same year he produced one of his most elaborate works, a "History of Christianity from the Birth of Christ to the Abolition of Paganism in the Roman Empire" (3 vols. 8vo), and in 1854-5 a "History of Latin Christianity, including that of the Popes, to the Pontificate of Nicholas V." (5 vols. 8vo), designed as a continuation of the former, although it is a complete work. He prepared a sumptuously printed and illustrated edition of Horace (8vo, 1849), with a life of the poet and criticisms on his writings, an annotated edition of Gibbon's "Decline and Fall of the Roman Empire," preceded by a life of the historian, a "Memoir of Lord Macaulay," a "Life of John Keats," and translations of the "Agamemnon" of Aeschylus, the "Bacchae" of Euripides, and some of the minor Greek poets. In 1862 he revised
MILNE

and almost completely rewrote his "History of the Jews" (3 vols. 8vo). His later works are: "Hebrew Prophecy, a Sermon" (1865); "Annals of St. Paul's Cathedral" (1868); and "Savonarola, Erasmus, and other Essays" (1870). In 1866-7 a complete edition of his "Historical Works" was published (15 vols. post 8vo). In 1849 Milman was made dean of St. Paul's.

MILNE, William, an English missionary, born in the latter part of the last century, died in China in 1822. In 1819 he visited China under the auspices of the London missionary society, and during the next two years travelled extensively through that country, Malacca, and the chief islands of the Indian archipelago, distributing many thousand tracts and Testaments among the natives. He subsequently established himself in Malacca, and founded a missionary station, which became one of the most important in eastern Asia. He continued to circulate the Scriptures, and also superintended the publication of religious works and of a monthly magazine. In 1817 he was again in China, where he projected the plan of an Anglo-Chinese college, aided in translating the Old Testament into Chinese, and originated the "Indo-Chinese Gleaner," a quarterly publication. He died in the midst of his labors. He is the author of a "Retrospect of the Protestant Mission to China."

MILNE-EDWARDS, Hurl, a French naturalist, born in Bruges, Belgium, Oct. 23, 1800. His father was an Englishman. He studied medicine in Paris and took his degree there in 1828, but abandoned practice for physiological pursuits. He occupied for a time the chair of natural history in the lyceum of Henry IV., and in 1841 accepted a similar post in the museum and the faculty of sciences, of which he became president. In 1838 he succeeded F. Cuvier in the academy of sciences, and in 1854 he was elected a member of the academy of medicine. In 1856 he received the Copley medal of the royal society of London. He was chosen in 1852 professor of zoology in the museum and faculty of sciences, and in 1864 assistant director in the same institution. His publications comprise Recherches anatomiques sur les crustacés (1828); Manuel de matière médicale (1832); Nouveau formulaire pratique des hôpitaux (4th ed., 1846); Cahiers d'histoire naturelle (1834); Éléments de zoologie (1834-5); Histoire naturelle des crustacés (3 vols., 1837-41); Histoire naturelle des corallifères, ou polypes proprement dits (3 vols., 1835-60); Leçons sur la physiologie et l'anatomie comparée de l'homme et des animaux (1855-65); Histoire des mammifères (1872 et seq.), &c. He also superintended the publication of a new edition of Lamarck's Histoire naturelle des animaux sans vertèbres (11 vols. 8vo, 1834-45).—His son Alphonse, born in Paris in 1835, is a professor in the school of pharmacy, and the author of several works on natural history.

MILNER, John, an English Roman Catholic author, born in London in October, 1782, died in Wolverhampton, April 9, 1826. He was educated at Edgbaston and Douai, and in 1799 was stationed at Winchester. His "History, Civil and Ecclesiastical, and Survey of the Antiquities of Winchester" (2 vols. 4to, 1798-9), led to religious controversy, and he issued "Letters to a Prebendary," Dr. Sturges (1800), and "End of Religious Controversy" (1818), which are regarded by Catholics as among their ablest books. Several answers to the "End of Controversy" have appeared. In 1803 he was made bishop of Castabala and vicar apostolic of the Midland district, and he took an active part in opposing the proposed granting of a veto to the English government on the appointment of Catholic bishops. His other works, chiefly occasional, are numerous, and include "Notes on Ireland," a life of Bishop Challoner, a supplement to Butler's "Memoirs of the Irish Catholics," and an investigation into the life of St. George.

MILNER, J. Joseph, an English historian, born near Leeds, Jan. 2, 1744, died in Hull, Nov. 15, 1797. He graduated at Cambridge in 1766, and after taking orders became head master of the grammar school and lecturer of the principal church of Hull. His most important work is a "History of the Church of Christ from its Foundation to the 18th Century" (3 vols. 8vo, London, 1794). It was continued by his brother to the reformation. A complete edition of his works, with an account of his life, was published by his brother in 1810, in 8 vols. 8vo. H. Isaac, brother of the preceding, born near Leeds, Jan. 1, 1751, died in London, April 1, 1820. On the death of his father he left school, and worked for a time in a factory; but his brother employed him as an assistant in the grammar school at Hull. In 1770 he entered Queen's college, Cambridge, where in 1774 he became senior wrangler, and in 1775 was elected a fellow. In 1783 he became professor of experimental philosophy, in 1786 master of Queen's college, and in 1791 dean of Carlisle. At Cambridge he formed an intimacy with William Wilberforce which endured through life, and he died in his house. His principal works are: a continuation of his brother's "History of the Church of Christ," "Animadversions on Dr. Haweis's Church History" (8vo, 1800), "Essay on Human Liberty," and two volumes of "Sermons."

MILNES, Richard Monckton. See HOUGHTON, Lorn.

MILNOR, James, an American clergyman, born in Philadelphia, June 20, 1773, died in New York, April 8, 1844. After spending a brief period at the university of Pennsylvania, he began the study of law in his native city in 1789, was admitted to the bar in 1794, and practised his profession at Norristown till 1797, where he removed to Philadelphia, where he served in several public stations. In 1810 he became a representative in congress, where he
opposed the war of 1812. He entered the ministry of the Protestant Episcopal church in 1814, and in 1816 was called to St. George's church, New York, where he remained till his death. Dr. Milnor's labors were abundant, not only in the discharge of his parish duties, but also in connection with the Bible and tract societies, and other philanthropic and charitable institutions. He published a few occasional sermons and addresses.—See "Memoirs of the Life of James Milnor," by the Rev. J. S. Stone, D. D. (Svo, New York, 1848).

**MILYO.** See Melos.

**MILYO,** or Milon, a Greek athlete of the latter part of the 6th century B. C., born in Crotona, Magna Græcia. His extraordinary physical strength gave him the victory in wrestling six times at Olympia, and as often in the Pythian games. He is said to have carried a four-year-old heifer on his shoulders four times around the Olympic race course, and then to have eaten the whole of it in one day. In 511 he was appointed to command an army against the Sybarites, and bore an important part in the battle of the Crathis. He was worsted by the agility of his adversary in his seventh Olympic struggle. When enfeebled by age, it is said, he attempted to tear asunder with his hands a forest tree partially split by woodcutters; he was caught and held fast by the closing of the fissure, and was devoured by wolves.

**MILYO,** or **Minias** Papinius, a Roman tribune and demagogue, born at Lanuvium in the early part of the 1st century B. C. In 57 he filled the office of plebeian tribune. At that period Clodius, at the head of a band of desperadoes, controlled the destinies of Rome, burning temples, attacking the houses of private citizens, shedding the blood of freemen in the streets, dispersing the comitia by violence, and trampling under foot all laws. Milo, who was little better than Clodius, but desirous of retrieving his ruined fortunes by an alliance with the aristocrats, temporarily restored order, after which Cicero was recalled from exile. Clodius, who had been the author of Cicero's banishment, assailed his person and property, and would have sacrificed him had not Milo come to his aid. The followers of Milo and Clodius fought daily in the streets. The rival chiefs and their retainers met at Bovilla, on the Appian way, in January, 52, and in the fray Clodius was slain. Milo was brought to trial, and Cicero, his advocate, was so intimidated that he did not venture to deliver the oration he had prepared; his client was convicted and went into exile to Massilia, where he remained till 48, when he returned to aid Marcus Caelius in resuscitating the republican party, but was defeated and slain in Lucania.

**MILTIADES,** an Athenian statesman, who flourished at the beginning of the 5th century B. C. He was of a noble family, son of Cimon, and nephew of the elder Miltiades, who was prominent in Athens in the time of Pissistratus, and was also the founder of a despotism in the Thracian Chersonese. He was sent out about 516 to take possession of his uncle's inheritance. To secure his position, he imprisoned the chief men by stratagem, employed a force of mercenaries, and married the daughter of a Thracian prince. He joined Darius Hystaspis on his expedition against the Scythians, and remained with the Ionians to guard the bridge over the Danube while the Persian army advanced northward. When the appointed time had passed, and nothing had been heard from Darius, he is said to have urged the destruction of the bridge and the abandonment of the Persians, but to have been overruled by the Ionian leaders, who maintained their own ascendency by Persian support alone, the feeling of the population being everywhere against them. Had his opinion prevailed, says Grote, he would have inflicted on Persia a more vital blow than the victory of Marathon. He remained in the Chersonese till about 498, with the exception of a brief interval. His only achievement during this period was the conquest of Lemnos and Imbros, which probably took place while the Persians were occupied with the Ionic revolt (between 501 and 494). He thus drew upon himself the hostility of Darius, was driven from the Chersonese at the close of the Ionic war, and on his flight to Athens narrowly escaped capture by the Phocian fleet. He was brought to trial by the Athenians for alleged despotism in his administration of the Chersonese, but was honorably acquitted, and his fame as the conqueror of Lemnos secured his election as one of the ten generals at a time when the Persian armament under Datès and Artaphernes was approaching Greece. While the generals were equally divided whether to meet the enemy in the field or to defend the city behind its walls, Miltiades persuaded the polemarch Callimachus to give his casting vote in favor of immediate attack, and thus brought on the battle of Marathon. Though the other generals surrendered to him their vote of command, it is said that he waited till his own day before he engaged the enemy, and achieved the most memorable victory in the history of Greece. (See Marathon.) The admiration of him by his countrymen was now unbounded. At his request, he was intrusted with an armament of 70 ships, no other man knowing its destination. He sailed against the island of Ægina to gratify a private animosity, and ravaged the island, but failed to capture the town. Being seized with a panic while visiting a priestess on a superstitious errand, he strained or bruised his thigh by falling and raised the siege. On his return to Athens he was impeached and condemned to pay a penalty of 50 talents, and soon after died of his wound. According to Cornelius Nepos and Plutarch, he was imprisoned after being fined, but this is not stated by Herodotus. The fine was afterward paid by his son Cimon.

**MILTON,** a N. county of Georgia, bounded S. E. by the Chattahoochee river, and watered by
several streams; area, about 150 sq. m.; pop. in 1870, 4,984, of whom 466 were colored. The surface is broken and the soil generally fertile. The chief productions in 1870 were 24,896 bushels of wheat, 98,093 of Indian corn, 15,351 of oats, 9,015 of sweet potatoes, 3,048 lbs. of wool, 24,026 of butter, and 2,758 gallons of cream molasses. There were 437 horses, 2,191 cattle, 1,921 sheep, and 4,998 swine. Capital, Alpharetta.

Milton, a township and post village of Rock co., Wisconsin, on the Chicago, Milwaukee, and St. Paul, and the Chicago and Northwestern railroads, 30 m. S. E. of Madison, and 62 m. by rail S. W. of Milwaukee; pop. in 1870, 2,010. It is the seat of Milton college, established in 1867 by the Seventh-day Baptists. This institution has normal, scientific, and classical (embracing preparatory and collegiate) courses. In 1873-4 it had 8 instructors, 208 students (76 of collegiate grade), and a library of 1,500 volumes. It admits both sexes.

Milton, John, an English poet, born in London, Dec. 9, 1608, died there, Nov. 8, 1674. His father had been disinherited at an early age for abandoning the Catholic faith, adopted the profession of scrivenor or copying lawyer, and retired with an independence. Though inclined to Puritanic habits, he had cultivated literature in his leisure, and holds a respectable rank among the contemporary composers of madrigals, songs, and psalms. Milton thus received the training of a Puritan family, and was also taught the art and science of music, becoming an accomplished organist. In his writings, whenever he speaks of music, he is always technically and strictly correct. His father secured for him the best educational advantages, and both as a boy and a man Milton was severely and constantly studious. He was still under the care of a private tutor when, being scarcely 12 years old, he was sent to the school of St. Paul's. Even at that age he seldom retired to rest from his studies till after midnight. There began his memorable friendships with Diodati and Gill. He was able to compose Latin prose and verse with ease and elegance, was familiar with Greek and Hebrew, and had "no mean apprehension of the sweetness of philosophy," when he was entered, Feb. 12, 1625, as a pensioner at Christ's college, Cambridge. Though destined to the church, he resolved early in his university career upon a life of continued study, with no professional aim, but with a view to authorship. He led a life of singular intellectual independence, did not conceal his disinclination to the scholastic sciences, and for a time was at variance with the authorities and was rusticated. His personal beauty is uniformly mentioned by those who describe his youth as very remarkable. His light brown hair, parted in the middle, fell in curls upon his shoulders; the expression of his clear gray eyes was serene and thoughtful; and, though he excelled in manly exercises, his fair complexion, slight figure, and innocent life caused him to be styled by his fellow colleagues "the lady of Christ's." On quitting the university in 1632, he took up his abode in the village of Horton, Buckinghamshire, whither his father had retired from London. There he spent the next five years in a ceaseless round of study and reading, devoting his time chiefly to the Greek and Latin poets. At this time he published the "Sonnet to the Nightingale," the companion pieces "L'Allegro" and "Il Penseroso," the masques of "Arcades" and "Comus," and the elegy of "Lycidas." None of his other compositions are so tranquil and happy in tone, or indicate so distinctly his love of the lighter graces of poetry. They are replete with rural imagery, delicate fancies, playful allusions, and sensuous descriptions, and the themes and the idyllic treatment strikingly contrast with the poems which he produced after 20 years of conflict in public life. On the death of his mother in 1637 he obtained his father's permission to travel on the continent, especially in Italy; and he set out in the following year, attended by a single servant. In Paris he was welcomed by the English ambassador and introduced to Grotius; in Florence, where he remained two months, he made the acquaintance of Galileo and was received into the literary academies, before which, according to custom, he gave evidence of his learning, and recited some of his Latin poems and three Italian sonnets, which won the encomiums of Italian wits and scholars; in Rome he made another stay of two months, protected by Lucas Holstein, the librarian of the Vatican, and by Cardinal Barberini. He abandoned his purpose of going to Sicily and Greece on receiving tidings of the impending rupture between the king and people in England, as he considered it dishonorable to be pursuing his own gratifications abroad while his countrymen were contending for liberty. He returned to England by way of Rome, where he again remained two months, and, though warned of Jesuitical plots, openly "defended the reformed religion in the very metropolis of popery" without fear or molestation. He reached home in August, 1639, after an absence of 15 months. He had already determined to write a great poem, but his meditations were interrupted by the civil commotions, and by a period of 20 years during which the literature of England was almost exclusively polemical. He entered into the political disputes of the day, and during the whole splendid and vexed era of Puritan supremacy in England, with the exception of a few sonnets, he appears only as a polemical prose writer and champion of the revolution. During his absence his father had broken up his household at Horton. Milton therefore hired apartments and afterward a house in London, and received his two young nephews Edward and John Phillips, sons of his sister Anne, to board with him as pupils. A few more pupils, sons of intimate friends, were afterward admitted;
and while pursuing his private studies he devoted a part of his time to their education after a peculiar system of his own. He was thus occupied with studying and teaching when he published his first pamphlet. The long parliament met in 1640; Laud and Strafford were overthrown; the danger from free speech was removed; and the circumstances of the time offered an invitation to thinkers. Prominent among topics of public interest was that of church reform, and Milton published a vehement attack on the episcopal form of government entitled "Of Reformation, touching Church Discipline in England, and the Causes that hitherto have hindered it" (1641). In the same year Bishop Hall of Norwich, at the request of Laud, undertook a defence of episcopacy, and was answered by a combination of five Puritan ministers under the title of Smeecyntnuus, a word composed of the initials of their names. Archbishop Usher replied to the Smeecyntnuans, and Bishop Hall published a defence of himself. Milton published two pamphlets in answer to the former, entitled "Of Prelatic Episcopacy" and "The Reason of Church Government urged against Prelaty," and a tract in the form of a dialogue entitled "Animadversions" upon Bishop Hall's defence. The last drew forth an anonymous and slanderous response, attributed to a son of the bishop; and the controversy was concluded by Milton's "Apology for Smeecyntnuus" (1642), in which he had held the clergy in contempt, and in which he was answered by the bishops. In 1643 he was resting from controversy, occupied with his pupils, and meditating the great poetic work to which he wished to transfer all his mental power and industry. But in the midst of civil war and of episcopal contemplations he contracted a singular marriage.

"About Whitsuntide," says Phillips, "he took a journey into the country, nobody about him certainly knowing the reason, or that it was more than a journey of recreation. After a month's stay, home he returns a married man, who set out a bachelor; his wife being Mary, the eldest daughter of Mr. Richard Powell, then a justice of the peace at Forest Hill, near Shotover, in Oxfordshire." It appears that his father had made a memorandum to him of a debt due from Powell, the larger part of which was never paid; that his numerous rides to Forest Hill in quest of money resulted only in a matrimonial engagement; that he never received a shilling of the £2,000 promised with his wife; and that he encountered "a mute and spiritless mate" where he had expected "an intimate and speaking help." Moreover, it was a marriage amid civil conflict between a renowned parliamentarian and a lady of a royalist family. She remained only one month with her husband, and then accepted an invitation from her family, probably suggested by herself, to go back and spend some time in the country; and at a secure distance she treated both the letters and messengers of the poet with contempt, and refused to return. The plea suggested on her side are that she was used to company and merriment, and disliked Milton's "sparing diet and hard study;" the poet's chief and singular ground of complaint was that his wife would not talk; it is probable that they simply disliked each other, and that nothing but an impudent marriage suggested to him "the pious necessity of divorcing," even in cases that depend upon "utterless facts." Milton came to the conclusion that other reasons, besides those legally admitted, might be sufficient for the dissolution of the nuptial tie, and determined publicly to argue his case. With the intellectual clearness and boldness which are his special characteristics, he pushed his ideas of civil and ecclesiastical liberty into the realm of the domestic circle; and he resolutely advanced the doctrine that moral incompatibility as well as conjugal infidelity justifies divorce. It should be noticed that he does not disguise his opinion of the natural inferiority of woman. His publications on this subject are: "The Doctrine and Discipline of Divorce restored to the Good of Both Sexes from the Bondage of Common Law" (two editions in 1644); "The Judgment of Martin Bucer touching Divorce" (1644), in which he shows that a celebrated contemporary of King Edward VI. had been of the same opinion as himself; "Tetrachordon, or Expositions" upon the four chief places in Scripture which treat of Marriage or Nullities in Marriage" (1645); and "Colasterion: a Reply to a Nameless Answer against the Doctrine and Discipline of Divorce" (1645). His efforts for a change of law were a failure, but he retained his opinions till the close of his life. The discussion of the subject which he raised was no less intolerant and impatient than that on episcopacy had been, and during its progress he was summoned to the bar of the house of lords, but was honorably dismissed. Meantime he had published his tractate "On Education" (1644), only the theoretical views of which are important, and had addressed to the parliament the noblest and most useful of his compositions in prose, the "Areopagitica, a Speech for the Liberty of Unlicensed Printing" (1644). It is a plea for freedom in literature; but though it contains some of his finest passages of prose eloquence, it was not successful in its aim of abolishing the newly established censorship. In 1645 appeared in a small volume the first edition of his poems. In the same year a reconciliation was effected between him and his wife. She returned to his house, and her whole family were generously entertained by him for several months. After their departure, his abode, says Phillips, "looked again like a house of the muses." He lived successively in the Barbican and in Holborn, and was occupied with writing his history of England when the execution of King Charles (Jan. 30, 1649)
had aroused throughout Europe a feeling of horror and indignation, and created a reactionary tendency even among the partisans of the revolution. Milton wrote "The Tenure of Kings and Magistrates," published within a month after the death of the king, in which he undertook to prove that subjects have a right to depose or put to death a wicked monarch. He also published "Observations" on the articles of peace which the earl of Ormond had concluded in the king's name with the Irish Catholics. On the establishment of the commonwealth, Latin was fixed upon as the official language of intercourse with foreign states.

To Milton, in view both of his scholarship and his services, was given the office of secretary for foreign tongues; and 16 letters and other documents first published by the Camden society in 1731 confirm all previous impressions of his skill in Latin composition, and of the eloquence, energy, and dignity he gave to the political despatches of the commonwealth. He vindicated the freedom of England on the seas, protested against the persecution of the Walenses by the duke of Savoy, and expounded to Europe the position and policy of the new government. The Eikon Basilike was passing through numerous editions, and winning popular sympathy for the "royal martyr," and he therefore prepared a counteractive under the title of Eikonoklastes (1649). Claude de Salmis, France, and one of the most distinguished contemporary scholars, was instigated by Charles II., then a refugee in Holland, to compose an elaborate defence of the inviolability of kings, and especially of royalty in England, in a treatise worthy to be submitted to the learned of Europe. The name of the author was sufficient to secure fame and extended influence to his work, and the council immediately made an order "that Mr. Milton do prepare something in answer to the book of Salmisius." This was the occasion of his Pro Populo Anglicano Defensio contra Salmasii Defensionem Regiam (1650), in which he assailed at once the philosophy and Latinity of his opponent, and surpassed him in scholastic vituperation. It was deemed a triumph, and he received the thanks of the council and the congratulations of the foreign ministers in London. His eyesight had been failing for several years, and his physicians informed him before he undertook this defence that total blindness was threatened; but he regarded the task as a sacred duty, and it hastened the mali-
dy, the "drop serene" (gutta serena), as it is termed in his plaintive account of it. Before 1654 he was completely blind, though his eyes were perfectly clear, and without mark, speck, or disfigurement. He had already removed to the house in Petty France, opening into St. James's park, in which he remained till the restoration, and which was afterward occupied by Hazlitt. In 1652 appeared Regni Sanguinis Clamor ad Calum, written by Dumonil, a Frenchman resident in England, but attrib-
uted to Moore (Morus), a Scotchman resident in France, abounding in calumnious invective against Milton personally. This occasioned his Defensio Secunda (1654), a noble defence of his own conduct, a vindication of the parliament, and a merciless retaliation for the scurrilities of his antagonist. The dispute was prolonged by two additional pamphlets on each side. Milton continued to write many of the more important state papers until the restoration, and was also occupied with his history of England, with framing a body of divinity, and perhaps with the composition of his great poem, the subject of which he had at length determined. He also opposed to the last in divers tracts and letters the return of the monarchy. For 20 years he had been the foremost literary champion of the principles of English liberty, then struggling for recognition. His polemical writings abounded in passages of the finest declamation, marked by a peculiar majesty of diction, and by a sustained and passionate magniloquence. The political theory which he advanced was in some respects peculiar to himself. He advocated a free commonwealth, without a sovereign or a house of lords. The government should be intrusted to a general council of ablest men, chosen by the nation, and he opposed the coexistence of any popular assembly. He would not even have the members of the council chosen directly by a popular vote, but recommended three or four "sifting and refining" processes. After the restoration, a proclamation was issued for the arrest of Milton, and two of his books were publicly burned. He lived in concealment till the act of indemnity placed him in safety. His first wife had died in 1652 or 1653, leaving him three little girls; he married a second time, Nov. 12, 1656, Cath-
line, daughter of a Captain Woodcock of Hackney; but his wife, whose memory is en-
balmed in one of his most beautiful sonnets, survived only 15 months; and about 1663 he married Elizabeth Minshull, daughter of Ralph Minshull of Cheshire. The last was a mar-
riage of convenience, arranged by a friend, because his daughters had ceased to treat him with kindness. They however lived in his house five or six years longer, in constant quar-
rel with their stepmother. Unsubdued by pain, obloquy, and blindness, amid domestic infeli-
cities and the profligacy of the era of the comic dramatists, and witnessing the public defeat of the principles which he had represented, he meditated and dictated the poems of "Paradise Lost" and "Paradise Regained." According to Ellwood, the former was completed and the latter was begun at Chalfont, whither Milton retired from London during the plague of 1665. "Paradise Lost" was sold to Samuel Simmons, bookseller, April 27, 1667, for £25 in hand, and a promise of the same sum on the sale of the first 1,300 copies of each edition, none of which was to exceed 1,500 copies. The second payment was received in 1669, the...
second edition was issued in 1674, the third in 1678, and in 1681 Milton's widow gave up to Simmons all her interest in the work for £8. This poem has been the subject of a great deal of criticism and research. Disraeli, in his "Amenities of Literature," has pointed out its remarkable similarity to the work of Cbedmon, an Anglo-Saxon poet; others attempt to trace the character of Satan to Vondel's Lucifer, and cite a recently discovered record of Leyden university (1874), which shows that Milton studied there, and probably acquired some knowledge of contemporary Dutch literature. "Paradise Regained," appeared in 1671, in the same volume with the drama of "Samson Agonistes." A second and enlarged edition of his minor poems was published in 1673. His principal later prose publications are the "History of Britain" (1670), down to the Norman conquest, containing many of the early traditions, much of which had been written before the restoration; a tract entitled "Of True Religion, Heresie, Schism, Toleration," and what best Means may be used against the Growth of Popery" (1673), in which he urges absolute toleration for all Protestant sects, but denies it to Roman Catholics; a short Latin grammar (1661); a compendium of logic (1679); and his Latin epistles and oratorical exercises in the university (1674). He left in manuscript a Latin treatise entitled De Doctrina Christiana, which had been unsuccessfully offered to Elzevir for publication. Two years after his death it came into the hands of one of the English secretaries of state, by whom it was deposited in the state paper office, where it was accidentally discovered in 1692. It was translated and edited (4vo, 1825) by C. R. Sunner, D.D., afterward bishop of Winchester, and it completely establishes Milton's Arianism, which had been suspected from passages in "Paradise Lost." Its heterodoxy was doubtless the reason why it was offered first to a Dutch publisher, and afterward withheld from the public. In his last years he was afflicted by the gout, which, according to Aubrey, "struck in" and caused his death. He died calmly and without pain, and his remains were laid beside those of his father in the church of St. Giles, Cripplegate. After his sight failed he had been accustomed to go to bed at 9 o'clock, and to rise at 4 o'clock in summer, and 5 in winter. Before rising, he often had some one to read to him or to write at his dictation. He studied till 12, with the intervention of breakfast, then exercised for an hour, dined, played on the organ or bass viol, and resumed his studies till 6, from which hour till 8 he conversed with visitors. He fancied that "his vein never happily flowed but from the autumnal equinox to the vernal," and was never satisfied with what he wrote in the other half of the year. He attended no church, belonged to no religious communion, and never had social prayers in his family. That he was somewhat haughty and overbearing, and of severe if not choleric temper, appears from other evidence as well as from passages in his controversial writings; yet his manners were usually urbane, and his conversation delightful. The principal biographies of Milton are those by Toland, Todd, Symmons, Dr. Johnson, Mitford, Keightley (London, 1859), and Masson (2 vols., London, 1859-71). The last is also a literary history of the time. The best edition of Milton's poetical works is Pickering's, with a life by the Rev. John Mitford (8 vols., London, 1851; the 2 vols. of poems reprinted, with Mitford's "Life," 1873). Among others are those of Bishop Newton (3 vols. 4to, 1749), the first critical edition: Todd, with variorum notes (6 vols., 1801); Hawkins (4 vols., Oxford, 1824); Sir E. Brydges (6 vols., 1831); C. D. Cleveland, with a verbal index (large 12mo, Philadelphia, 1853); Keightley (2 vols. 8vo, 1859); W. M. Rossetti, with memoir (8vo, 1871); David Masson (1874); and the minor poems by T. Warton (1785). The prose works were first collected by Toland (3 vols. fol., 1697-8), and have since been edited by Birch (2 vols., 1753), Charles Symmons (7 vols., 1800), Robert Fletcher (8vo, 1820), and Rufus W. Griswold (2 vols. 8vo, Philadelphia, 1845); but the only complete edition is in Bolin's "Standard Library" (5 vols. post 8vo, 1848-53). A concordance to the poems by Prendergast was published at Madras in 1857. A German translation of his principal political writings (Politische Hauptschriften) was published in Berlin in 1874 by Dr. W. Bernhardi, with annotations.

MILUTIN, or Milyutin, Nikolai Alexeyevitch, a Russian statesman, born April 29, 1818, died in Moscow, Feb. 7, 1872. Being born on the same day with the grand duke Alexander, he was educated at the expense of Car Nicholas, at the lyceum of Moscow, where he graduated in 1835. Nicholas then gave him a free scholarship at the university of St. Petersburg, where he completed his studies in 1838. He became supernumerary, and in 1842 vice president, of the imperial chamber of court accounts. In 1844 he was appointed chief of the press bureau, which post he soon left to undertake the revision of the Russian municipal laws. The czar next appointed him a member of the committee on the condition of the Russian serfs. Though Nicholas did not venture to act upon Miltin's advice in favor of emancipation, he appointed him under secretary of the interior. After the accession of Alexander II. (March 2, 1855), Miltin became his confidential adviser. He countersigned the ukase of emancipation, March 3, 1861, and prepared the laws necessary for this reform. He was made minister of the interior, and the new criminal code, the press law, and the introduction of the jury system are chiefly his work.

MILWAUKEE, a S. E. county of Wisconsin, bounded E. by Lake Michigan; area, 340 sq. m.; pop. in 1870, 89,930. It is watered by the Milwaukee, Menominee, and Root rivers. The surface is undulating, and the soil calcareous.
MILWAUKEE, the chief city and port of entry of Wisconsin, capital of Milwaukee co., on the W. shore of Lake Michigan, in lat. 43° 3′ N., lon. 87° 54′ W., 75 m. E. of Madison, and 85 m. N. by W. of Chicago; pop. in 1840, 1,712; in 1850, 20,061; in 1860, 45,246; in 1870, 71,440, of whom 33,773 were foreigners, including 22,599 natives of Germany, 3,784 of Ireland, 1,453 of Bohemia, and 1,906 of Scotland.

There were 14,226 families and 13,048 dwellings. The population in 1874 was estimated by local authorities at from 95,000 to 100,000. The lake opposite the city makes an indentation in the shore, forming a bay 6 m. wide and 3 m. deep, which is easy of access at all seasons. The Milwaukee river, which flows through the city, and is joined near its mouth by the Menominee, has been rendered navigable to the heart of the city by vessels of any tonnage used on the lakes. It is regarded as the best harbor on the S. or W. shore of the lake. The climate is peculiarly bracing and healthful, and the atmosphere is remarkably clear and pure. The city is regularly laid out. The centre, near the Milwaukee and Menominee rivers, is the business quarter; and the E. and W. parts, the former of which is built upon a high bluff overlooking the lake, while the latter is still more elevated, are occupied by residences. The material used in building is largely the beautiful cream-colored Milwaukee brick. The streets, except those in the commercial quarter, are generally well shaded. There are three lines of horse cars. The principal public buildings are the new county court house, the United States custom house and post office building, the academy of music, the opera house, and the Milwaukee Academy of Music. Milwaukee has railroad communication with the iron mines of Michigan, with the principal points of Wisconsin, with Chicago, St. Paul, and the railroad system of the east and west, by means of the Milwaukee and St. Paul, the Western Union, the Chicago and Northwestern, the Wisconsin Central, and the Milwaukee, Lake Shore, and Western lines. The receipts and shipments by these lines and by the lake are of great extent and value; wheat and flour are the most important items. The number of vessels entered in the customs district (which includes the entire lake shore of the state) from Canada, for the year ending June 30, 1873, was 49, with an aggregate tonnage of 14,435; cleared for Canada, 135, tonnage 39,324; value of imports, $222,055; of exports, $3,018,906. The value of goods received under the act of 1870 permitting shipments in bond from the ports of first arrival to interior ports was $76,592. The entrances in the coastwise trade were 2,979 steamers, of 2,026,054 tons, and 4,722 sailing vessels, of 553,925 tons; clearances, 2,949 steamers, of 2,011,550 tons, and 4,432 sailing vessels, of 545,193 tons; belonging in the district, 235 sailing vessels, of 36,252 tons, and 58 steamers, of 13,867 tons; built during the year, 37 vessels, of 8,493 tons. The number of arrivals at

Milwaukee.
MILWAUKEE

Milwaukee alone during 1873 was 5,561, of 2,223,786 tons; departures, 5,535, of 2,223,857 tons; belonging to the port at the close of the year, 120, with an aggregate tonnage of 23,276. There are several vessels engaged in the lake fisheries. The receipts and shipments of flour and grain to and from the city since 1860 have been as follows:

The receipts of other grain in 1873 included 921,391 bushels of Indian corn, 376,834 of rye, 1,765,066, of oats, and 1,098,474 of barley; shipments, 197,950 bushels of Indian corn, 255,928 of rye, 990,523 of oats, and 688,455 of barley. There were also received during that year 3,550,194 lbs. of butter, 203,416 hides, 59,969 sheep skins, 241,099 live and 158,955 dressed hogs, 17,252 beef cattle, 11,745 sheep, 186,017,000 ft. of lumber, 93,233,000 shingles, 11,000,000 ft. of lath, 259,877 tons of coal, 222,951 barrels of salt, 2,681,927 lbs. of rags, 5,922,840 of Wisconsin tobacco, and considerable quantities of hops, cranberries, peas, beans, cheese, eggs, &c. There were shipped 2,842,501 lbs. of butter, 3,183,042 of wool, 54,234 hides, 17,997 live hogs, 10,261 beef cattle, 10,291 sheep, 4,216,420 lbs. of Wisconsin tobacco, 137,111 barrels of salt; 80,010 barrels of pork, 24,954 tiers of hams, 2,211 boxes of middle and sides; 1,915,610 lbs. of bulk meat, 4,065 barrels and 24,399 tiers of lard, 3,565 barrels and 463 tiers of beef, equivalent in the aggregate to 329,267 barrels of 200 lbs. each, and valued at not less than $3,900,000; and (by rail) 29,701,465 ft. of lumber, 24,997,150 shingles, and 630,400 ft. of lath. The storage accommodations for grain, comprising five elevators with a combined capacity of 2,450,000 bushels, have been inadequate for the trade; but in 1874 a new elevator with a capacity of 1,000,000 bushels was erected. Pork packing, in which six firms are engaged, is extensively carried on. The number of hogs packed in the regular packing season (Nov. 1 to March 1) of 1873-4 was 296,142, of an average net weight of 204 lbs. The manufactures are extensive, and embrace lager beer (which is highly esteemed and widely exported), pig iron, iron castings, flour, leather, malt, machinery, agricultural implements, highwines, tobacco and cigars, furniture, brooms, paper, woolens, wagons, soap and candles, doors and windows, boots, shoes and socks, steam boilers, car wheels, baskets, trunks, and white lead. The product of the blast furnaces and rolling mills for 1873 was valued at about $3,500,000; of the flouring mills, $5,000,000; of the breweries, $2,600,000; of the distilleries, $1,500,000; and of the tanneries, $3,000,000. The Milwaukee iron company is engaged in the manufacture of pig iron, railroad iron, and other kinds of merchant iron; the Minerva furnace company produces pig iron. The receipts of ore were 105,427 tons, shipments 26,910; receipts of pig iron, 11,457 tons; manufactured in the city, 85,120 tons; shipped, 8,330 tons; receipts of railroad iron, 6,999 tons; manufactured in the city, 34,494 tons. The number of breweries is about 20; quantity of beer sold in 1873, 290,130 barrels; distilled spirits or highwines manufactured, 29,207 barrels, of which a considerable portion was redistilled and converted into alcohol. There are 13 mills, which, besides the flour, produced more than 46,000,000 lbs. of bran and middlings, and three ship yards. The number of hoes tanned was 149,082. In 1874 there were four national banks, with an aggregate capital of $700,000; circulation, $567,400; deposits, $2,508,752; resources, $4,706,252. There were four state banks, with an aggregate capital of $236,935; deposits, $3,480,106; resources, $4,427,011. The two savings banks had a joint capital of $125,000; deposits, $1,403,959; resources, $1,553,957. There are four private banks, four fire insurance companies, and one life insurance company. The aggregate receipts of the banks in 1873 amounted to $451,686,356 90, which sum is regarded as a fair indication of the total volume of business of all kinds transacted in the city during that year. —Milwaukee is divided into 13 wards, and is governed by a board of aldermen of one member and a common council of two members from each ward. There is a municipal court, presided over by a single judge. The police force consists of a chief, two lieutenant, four detectives, two station keepers, a pound keeper, and 40 patrolmen. The fire department has five steam fire engines.
and a fire alarm telegraph. The city is supplied with water from the lake by water works recently erected. The United States courts for the E. district of Wisconsin hold two sessions here annually. The assessed value of property in 1873 was $48,559,817; expenditures for general purposes, $395,392.07; total debt April 1, 1874, $2,464,986.74. The northwestern national asylum for disabled soldiers is about 3 m. from the city. It occupies a brick building, having accommodations for 700 or 800 inmates, with which are connected shops and stables, The grounds embrace 425 acres, more than half of which is under cultivation, the residue being laid out as a park. The institution has a reading room and a library of more than 2,500 volumes. The present number of inmates is about 400. In the city there are three orphan asylums, a home for the friendless, and two hospitals. The public schools, 21 in number, are graded, and are held a high school. In 1872 there were 38 male and 127 female teachers employed; number of pupils enrolled, 11,294; average attendance, 7,100. The number of private schools was 47, with 7,000 pupils. Milwaukee female college had 6 instructors and 118 students, of whom 44 were of collegiate grade. The library of the young men's association contains 11,000 volumes, and that of St. Mary's institute 1,000. There are 8 daily (4 German), 1 tri-weekly, 2 semi-weekly, and 16 weekly (6 German) newspapers, and 1 semi-monthly (German) and 5 monthly (German) periodicals. The number of churches is 59, viz.: 3 Baptist, 1 Calvinistic Methodist, 1 Christadelphian, 5 Congregational, 1 Dutch Reformed, 5 Episcopalian, 4 Evangelical Association, 1 German Reformed, 2 Jewish, 10 Lutheran, 1 Lutheran Reformed, 9 Methodist Episcopalian, 5 Presbyterian, 10 Roman Catholic, and 1 Unitarian.—Milwaukee was settled in 1836, and incorporated as a city in 1846.

MILYAS. See Lyca.

MINERMUS, a Greek poet, born in Smyrna, flourished from about 634 to 600 B.C. As a colonist from Colophon, he was called the Colophonian. He was a flute player as well as a poet, and set his poems to music, using the plaintive melody called the νούς κοπαίς (melody of the heart). He fixed the form of elegiac poetry, and has been called its inventor. The most important of the surviving fragments of his works is his celebrated poem Ναννο, the most ancient erotic elegy of Greek literature. They have been published separately by Bach (Leipsic, 1826), and have been translated into German by several distinguished authors. The best edition of his works is by Schenewein, in the Delectus Poetarum Elegiacorum Graecorum (Gottingen, 1838).

MIMOSA (Gr. πιμός, a mimic, as some of the plants imitate the movements of animals), a genus of leguminosae which is so unlike in structure to the majority of the order as to serve as a type of a suborder, the mimoseae. These have small regular flowers in a spike or head, with stamens twice as many as the petals and leaves (sometimes simple phyllidia), twice or thrice pinnate. The genus mimosa was originally very large, but it has been so subdivided that now it includes only about 200 species, which are herbs, under-shrubs, or climbers, very few being erect shrubs or trees. The best known species is the sensitive plant (M. pudica), noticeable for its irritable leaves; others in the genus possess the same property, but in a less marked degree, and in all the leaves fold and take a sleeping position at night. The sensitive plant is a native of Brazil, and has been in cultivation more than 200 years; it is usually treated as an annual, when it grows only about a foot high, but if kept under glass it will grow 3 ft. high or more, and form a straggling shrub with weak spiny branches which are beset with bristly hairs; the alternate leaves are bipinnate, usually four pinnae, each bearing numerous small leaflets; the flowers are in small rose-purple heads, and are succeeded by short bristly pods containing the seeds; these retain their germinating power for a long time, in illustration of which it is mentioned that the jardín des plantes has been continuously supplied with sensitive plants by seeds from a bag that was brought there more than 75 years ago. It is sparingly naturalized in Florida. The sensitiveness of the foliage of this plant, manifested by a peculiar shrinking when touched, is one of the most striking phenomena of plant life; when undisturbed and in a bright light, the leaves stand nearly at right angles to the stem, but a slight touch causes them to fold and droop as if dead. This change in the position of the leaf is completed in three successive movements: first the leaflets close in pairs, bring their faces together, and incline forward; then the secondary petioles or branches of the leaf approach each other; and finally the main leaf
MINA BIRD. See Mixo Bim.

MINAS GERAES, an inland province of Brazil, bounded N. by Bahia, E. by Bahia, Espirito Santo, and Rio de Janeiro, S. by Rio de Janeiro and Sao Paulo, and W. by Goyaz; area, about 280,000 sq. m.; pop. in 1871, 1,450,000. The face of the country is extremely irregular. Several mountain chains traverse it, especially in the south and west, sending out spurs and minor ridges which cross the province in every direction, and are separated by extensive and fertile valleys, watered by large rivers. The highest summits are Itacolumé (about 5,700 ft.) and Itambé (6,000). The principal river is the São Francisco, which divides the province into two almost equal portions. Other large rivers are the Belmonte, Mucury, Doce, Paranahyba, Grande, and Verde Grande. Many of these, as well as the São Francisco, have large tributaries, such as the Jequitinhonha and the Rio das Velhas; but none of them are navigable throughout. Minas Geraes was formerly famous for its mines (whence its name), at once the richest and most numerous in Brazil, especially the gold mines of Ouro Preto, the capital, Morro Velho, and Minas Novas; but most of them have been abandoned, and even the washings, though known to be profitable, are for the most part unworked, agriculture or diamond washing on the Jequitinhonha being preferred. Upon the discovery of diamonds in 1746, the government, to encourage the search for these gems, prohibited the extraction of gold. Rubies have occasionally been found; grisolites (chrysoberyls), pingos d'água (white topazes), and other precious stones abound in the Mucury, the Rio das Americanas, &c. Although Minas Geraes is entirely within the tropics, it has, owing to its mean elevation of about 2,000 ft. above the sea, a generally mild and healthy climate. Vegetation is everywhere luxuriant; the forests contain vast quantities of timber and valuable cabinet woods; dyes of various kinds and several species of medicinal plants abound; and whole districts, covered with brilliant flowers, presenting the aspect of continuous gardens, are not uncommon. The soil is fertile, and yields plentiful crops of the various cereals; maize, millet, manioc, and cotton are the staple productions; tobacco thrives well; and the coffee is only inferior to that of Ceará. Great numbers of cattle pasture on the plains under the care of vaqueiros, and the rearing of cattle and hogs is one of the principal occupations. There is a great variety of wild animals, birds, serpents, and insects. A prosperous trade is carried on with Bahia, Rio de Janeiro, and Sao Paulo; the articles exported are cattle, hogs, bacon, cheese, cotton fabrics, tobacco, coffee, skins, precious stones, drugs, &c. Manufactures, wine, flour, wheat, and salt are imported. With the exception of the great Union and Industry road, the facilities for transport are meagre, and goods are mainly carried on mule-back, which greatly enhances the price of all articles imported. There are forges, founderies, and cotton and woollen weaving establishments in many of the towns; wool hats, rum, sugar, and tobacco are manufactured on a large scale. Besides the colleges in the principal towns, there are upward of 250 primary and grammar schools in the province.—Minas Geraes was made a province in 1833. It is divided into 14 comarcas or districts. The capital is Ouro Preto, formerly Villa Rica; and other important towns are Mariana, Minas Novas, Januaria, Diamantina, and Sao Joao d'El Rey.

MINATITLAN, a small town of Mexico, isthmus of Tehuantepec, on the W. bank of the Coatzacoalcos, 20 m. from its mouth and 125 m. S. E. of Vera Cruz; pop. about 2,500. It has obtained some notoriety and importance from being the Atlantic point of departure in the various attempts to establish an interoceanic communication by way of the isthmus of Tehuantepec. It is also the proposed terminus of the projected railway across that isthmus on the north. The country immediately around the town is low and subject to periodical inundations. Cattle constitute the chief wealth of
the people. Mahogany and other valuable woods are produced in the vicinity, and shipped at Vera Cruz.

MINCIO (anc. Mincius), a river of N. Italy, which runs, under the name of Sarca, from the S. extremity of Tyrol into the lake of Garda, at Riva, issues from it at Peschiera, where it takes the name of Mincio, and flowing southward forms the boundary between the provinces of Verona and Mantua; then, past Goito, turning S. E. it expands into a lake, near the E. end of which is the fortress of Mantua; below this it discharges itself into the Po, near Governolo, after a course of more than 40 m. from the lake. It is navigable for barges throughout the greater part of its length. A battle was fought on the banks of the Mincio in 197 B. C., in which the Insul- bres and Cenomani were defeated by the Romans. Bonaparte crossed the Mincio in May, 1796; and the Austrians under Bellegarde were defeated there by Brune, Dec. 25 and 26, 1800, and upward of 4,000 of them taken prisoners. Another victory over the Austrians was achieved there by the French under Engue Beaugarnais, Feb. 8, 1814, after a bloody conflict. In 1859 the Mincio became again the theatre of war between the allied Sardinians and French and the Austrians, the latter endeavoring to concentrate their resistance on the line of the river. After the battle of Solferino (June 24), the allied armies crossed the Mincio into Venetia, and the war was brought to a close by the peace of Villafranca (July 11), by which Lombardy was transferred from Austria to Sardina, and the upper Mincio became a part of the boundary between the two states. This boundary ceased to exist in 1866, when Venetia was united with Italy.

MINDorf, a Swiss painter, better known under the name of Berner Friedli, born in Bern in 1768, died there, Nov. 7, 1814. He was educated in the charity school of Pestalozzi, devoting himself to the study of design. Ignorant in other education, and deformed, he shunned society, and spent his life among cats, of which he executed such excellent pictures that he was called the Raphael of cats. He also excelled in pictures of bears, children, and beggars. He died in poverty. Since his death his pictures have commanded extravagant prices, and several of them have been engraved.

MINDANA. See PHILIPPINE ISLANDS.

Minden, a fortified town of Westphalia, Prussia, capital of a district of the same name, on the left bank of the Weser, 80 m. E. N. E. of Münster; pop. in 1871, 16,593. It is one of the oldest towns of Germany, is surrounded by walls with six gates, and has a Garrison of 4,000 men. It contains a Roman Catholic cathedral of the 11th century, and was once the capital of the see of Minden, which was founded by Charlemagne, but was suppressed in 1648. It has a gymnasium, a normal school, manufactures of woollens, linens, leather, sugar, and tobacco, and an important trade chiefly in grain, linen, yarn, and brandy. It was the residence of some of the German emperors, and several diets were held there. Within 2 m. of Minden the railway traverses the pass called Porta Westphalica. In a ruined chapel near it Wittekind, according to tradition, was baptized by Charlemagne. The French were defeated in the vicinity of Minden, Aug. 1, 1759, by an Anglo-Hanoverian army under Ferdinand of Brunswick.

MINDORO. See PHILIPPINE ISLANDS.

MINE, an excavation made in the earth for the extraction of minerals. When the material to be extracted is a rock of any kind, the excavation is known as a quarry. We find very little in classic literature that gives any real information about the mines of antiquity or the manner in which they were worked. It is certain, however, that the Phoenicians and Egyptians at the earliest periods of history had an abundance of metals. The Phoenicians obtained from Sardinia and from other islands of the Mediterranean gold and iron, as well as other metals; they are known to have mined in Spain, probably for lead and silver, and to have traded with the Britons for the tin ore of Cornwall and Devon. Of even greater antiquity was the mining of the Egyptians, who had mines of copper, silver, and gold in productive operation, both on the Ethiopian and the Arabian border. The Sinaitic desert contains the ruins of mining works, probably executed by the Egyptians. Abraham found gold and silver mines in Arabia Felix, no traces of which remain. The Athenians worked rich silver mines in Attica and gold mines in Thrace and Thassos. Thessaly produced gold, Beotia iron, and Epirus silver. Before the time of the Romans mining was carried on in many parts of western Europe. The Etruscans and the Sabines in Italy were acquainted with copper, and the former discovered iron in Elba. The northern tribes of Italy obtained gold by washing; the tribes of Gaul are known to have mined for gold, silver, copper, and iron; and in Spain and Sardinia extensive and productive mines were established by the Carthaginians. Britain produced gold, silver, iron, lead, and tin. After the conquest of Cesar, the tin of Cornwall was shipped first to the Isle of Wight, and thence to the coast of Gaul, where it was loaded upon horses and transported to Marseille, a journey of 30 days. The early Romans did not work the mines of their native land. The first two Punic wars delivered into
the power of Rome the important mines of Sardinia, Sicily, and Spain. Subsequent conquests added those of Asia Minor, Macedonia, and Greece, and still later the remaining mines of western Asia and those of Egypt were acquired by the armies of Pompey and Augustus. Those of Gaul yielded to Caesar. The tin mines of Britain were their latest conquests of this sort, and Rome was then mistress of all the important mines of the ancient world. Under the republic the mines were worked by lessees, who employed numbers of slaves, and subjected the mineral deposits of the provinces to rapid and reckless robbery. During the period from the first Punic war to the empire there was an immense production of metals, and many of the mines were exhausted. The emperors established governmental supervision, and worked the mines through regularly appointed officials. Mining in the countries belonging to the West Roman empire declined rapidly from the 3d century, and after the 5th it ceased entirely. The Byzantines gradually surrendered their mines to the Arabs; those of Asia Minor, Thrace, and Greece were the last which the eastern empire retained.—Mining is known to have been carried on at Andreasberg in the Hartz since the year 968. The famous Rammelsberg mines were discovered in 1767 by the pawning of a steed named Rammel, tied to a tree in the forest. The Freiberg district was discovered about 1165, and has been steadily worked since 1547. Traces of ancient mining in the United States are confined to the copper region of Lake Superior, and to certain districts in New Mexico. In both cases the implements seem to have been rude hammers of stone. In New Mexico there is a large excavation known as the Turquoise mine, from which a trachytic rock, carrying turquoise in seams, has been laboriously extracted by a race of whom not even a tradition now exists. In ancient times muscular force, assisted only by applications of fire and occasionally by the power of water, was the miners' resource. A most suggestive picture of rude mining operations is given in the book of Job, xxviii. 1-11, of which Conant's translation brings out the beauties very strikingly:—

"For there is a vein for the silver, and a place for the gold, which they refine. Iron is taken out of the dust, and stone is fused into copper. He puts an end to the darkness; and he searches out, to the very end, stones of thick darkness and of death-shade. He drives a shaft, away from man's abode; forgotten of the foot, they swing suspended, far from men! The earth, out of it goes forth bread; and under it is destroyed as with fire. A place of sapphires, are its stones; and it has cloths of gold. The path, no bird of prey has known it, nor the falcon's eye glanced on it; nor proud beasts trod on it, nor roaring lion passed over it. Against the flinty rock he puts forth his hand; he overturns mountains from the base. In the rocks, he cleaves out rivers; and his eye sees every precious thing. He binds up streams that they drip not; and the hidden he brings out to light."—Pliny ("Natural History," xxxiii., 4) gives a similar description of shaft-sinking operations:—"Elsewhere pathless rocks are cut away, and are hollowed out to furnish a rest for beams. He who cuts is suspended with ropes. . . . For the most part they swing suspended, and fasten up lines for a pathway. They go where there is no place for the footprints of man." The removal of surface material by sluicing was also practised in ancient times in Spain.—The operations of mining may be comprised under four heads: 1, the discovery of mineral deposits and the testing of their value; 2, the establishment of access to such deposits; 3, the extraction of the mineral; 4, the protection of the works and workmen. I. Discovery and Testing of Mineral Deposits. For a description of the modes of occurrence of the rocks and minerals which are objects of mining, see MINERAL DEPOSITS. The presence of such deposits is indicated by various signs. Sometimes the veins themselves, if harder than the enclosing rocks, crop out at the surface unaltered. More frequently the outcrop is indicated by decomposed rock, which when ferruginous is called "gossan." Loose pieces of gangue and ore, known to western miners as "float quartz," and found upon the surface and in the soil, frequently lead to the discovery of veins. The lead miner of the limestone districts of the Mississippi valley is guided by depressed lines upon the surface, indicating the existence of fissures. The magnetic needle is employed in the discovery of certain ores of iron, and the ancient superstition of the divining rod for the discovery of hidden springs and mineral veins is not yet extinct even in this country. (See DIVINING ROD.) When the neighborhood of a mineral deposit is suspected and no certain indication of its exact locality appears, it is sought by prospecting pits, cuts, drifts, or borings. Prospecting pits are commonly dug upon the supposed outcrop of a deposit, to test its dimensions and quality. Open cuts are usually run on the surface at right angles to the prevailing course of the veins of the district, and are excavated down to the solid rock for the purpose of exposing the veins which they may cross. This is called "costeening." Boring is employed for determining the character of rock strata, and the position of mineral deposits in them. It has been usually applied to coal beds or to strata containing salt or petroleum deposits. In the latter cases the bore-holes subsequently serve for the extraction of brine or oil. The invention of the diamond drill (see BORING), by means of which holes can be driven in advance horizontally for hundreds of feet, has greatly enlarged the applications of boring as a means of exploration. Horizontal adits, or crosscuts, driven into the sides of hills at right angles with the veins known to exist in them, are the
However, the most expensive method of exploration. It may be resorted to when the existence and value of the deposits are well known, and the topography is such that the entry may subsequently be valuable for drainage and transportation. Finally, new deposits may be discovered underground by driving experimental openings from mines already in operation. The value of deposits is tested by shafts and drifts, usually excavated within the deposit itself. The construction of such works in the barren rock is seldom undertaken until the vein is found to be worthy of the expenditure. In the case of coal, building stone, iron ore, and, in general, all materials which occur in extensive and tolerably uniform deposits, and the value of which is small in comparison with their bulk, the test of quality is not difficult. But when the value of the deposits is concentrated value usually occur mixed with such variable proportions of "gangue" or barren matter, and when in fissure veins are subject to such variations in width and course, as to render it necessary to expose considerable bodies of vein matter, and to make tests either by thorough sampling or by actual reduction of large quantities, before the economical value of the deposits can be ascertained. By connecting with the shafts or inclines sunk upon the dip of the vein longitudinal drifts run upon its course, this object can be measurably secured. Alluvial deposits, such as those of gold and stream tin, are tested by actual working with pan, sluice, &c. When large operations, like those of hydraulic mining, are contemplated, the body of earthy gravel, cement, &c., if its value is not already known, is tested by shafts sunk to the bed rock at a sufficient number of points to give an indication of its average contents. II. APPROACHES TO MINES. Access to mineral deposits for permanent exploration is established, first, by suitable wagon or tram roads on the surface, and secondly by either stripping the overlying soil and rock from the deposit itself, as is done in quarries, clay banks, and some iron mines, or by sinking a shaft or running a drift or crosscut from the surface into the deposit. In the case of beds or veins which dip at a convenient and uniform angle, the shaft may be carried down upon the deposit itself, and is then usually called a slope or an incline. For less regular deposits, and for those in which the angle of inclination is inconvenient or variable, or the vein matter is of too valuable to permit the leaving of it in pillars to protect the shaft, it is better to drive a vertical shaft at some distance from the outcrop, in the hanging wall, so as to strike the vein at a considerable depth. A gallery run from the surface in a nearly horizontal line, to effect access and drainage, is called an adit or entry, and in some situations, as at the base of steep hills, this may be made the principal feature of the mine, the main workings being carried on through it until the vein is exhausted above its level. Sometimes the nature of the shafts permits the opening of mines at different levels, by means of adits. This system was most highly esteemed before the improvements in machinery and the introduction of steam favored the economy of mining in deep shafts. When adits must be driven for long distances through hard and barren rocks, it is sometimes difficult to decide whether the cost of their construction will be repaid by the saving in hoisting, drainage, and mechanical ventilation. Adits are usually carried on by miners of the Pacific states and territories, but this is a misnomer, as a tunnel proper extends entirely through a hill. Mining shafts are generally rectangular in section, and range in size from 3 or 4 ft. to 6 ft. on the shorter sides, and from 6 ft. to 20 ft., or even more, on the longer sides. This form facilitates timbering, and at the same time permits the best utilization of space, through the division of the shaft by partitions into separate compartments for pumps, hoisting, ladder ways, &c. Adits are placed with reference to securing the greatest depth below the surface by running as short a distance as possible, particularly in barren rock; with reference to the presence of a good place for a "dump" at the adit mouth; and also with reference to easy escape of waters, freedom from flooding by freshets, and facility of natural ventilation when the adit is to be connected with a shaft. For the latter purpose it is well that the adit mouth should not be in a narrow ravine or in the corner of a valley. Dimensions of adits depend upon the amount of water expected to run in them and the other purposes to which they are to be put. When in barren rock, it is an object to make them as small as practicable; 7 ft. high and 5 to 6 ft. wide is a convenient size. But when transportation is to be carried on and double tracks are to be laid, the dimensions must be increased. The height of the adit available for passage is diminished by the water channel, which usually runs under the floor or in a ditch at one side. The grade of adits is determined with reference to the amount and character of the water flowing in them and the speed which it is desirable to give to the current. The ancient mining regulations of Prussia required of deep adits a grade of from 1 in 800 to 1 in 400. Some of the adits at the coal mines of Saarbrück rise at the rate of 1 in 1,600; others at the rate of 89 in 64,000. According to the Saxon law, the grade may vary between 3 in 10,000 and 1 in 1,000. The long Ernst August adit in the Hartz has, for a length of nine miles, an average grade of 0'67 in 1,000. Here the water in the adit is itself used for transportation, and the current is intentionally kept slow. Access is further obtained to the different parts of the mineral deposit by subordinate shafts and galleries excavated in the deposit. These interior shafts not extending to the surface are known as winzes, and usually serve to connect the galleries on different levels. The galleries are known.
as levels or drifts in vein mining, and gangways in coal mining. When a mine is opened by a vertical shaft, the vein is sometimes cut by a crosscut level run from the shaft through barren rock, at a point higher than the intersection of the shaft and the vein. From the point where the crosscut enters the vein, levels are then run in both directions horizontally on the vein. After the main shaft has reached the vein and has been carried through it, the distance between vein and shaft of course grows larger with increasing depth, and the vein must be again opened by crosscuts from the shaft at different levels. The levels opened in the vein are so many parallel roads on the vein, succeeding each other every 60 to 100 ft. in depth. The winzes connecting them serve both in ventilation and in extraction, besides affording convenient access to different parts of the mine. The running of drifts to make connection with old and abandoned workings is sometimes dangerous, when the old workings are full of water and their exact position is not known by surveys. In such a case the approach is made cautiously, and a bore-hole is kept in advance, to tap the accumulated waters in such a way as to avoid an excessive flow or give the workmen time to escape. An accident of this kind at the Gouley mine, near Aix-la-Chapelle, in 1833, which caused the drowning of 63 miners, gave rise to the publication by the government of the Rhenish province of exact regulations, which constitute an excellent guide to the mining engineer. III. EXTRACTION OF MINERALS. To perform the work of regular extraction with due economy and safety, the following circumstances must be considered: the shape of the deposit, as a tabular or sheet deposit, a mass or stockwork, regular or irregular, &c., and if a tabular deposit, like a fissure vein or a bed, then its course and dip, its folds, basins, faults, and breaks; the thickness and inner structure of the deposit, or, in ore veins, the nature and distribution of the ore bodies, the amount of barren gange, and in coal beds and other deposits the proportion of marketable to waste material; the character of the "country" or wall rock, as making a solid or a precarious roof, and requiring more or less support; the number, relation, and distance apart of several deposits which it may be desirable to work at once or successively, as for instance seams of coal, lying one under the other; the conditions of ventilation, particularly where explosive gases are to be feared; the conditions of drainage; the character, abundance, and price of materials for underground supports (timber, masonry, iron pillars, loose rock, or earth); the size and shape of the pieces of material to be extracted (commercially important in coal and quarried stone); the method of excavation to be employed (picking, shovelling, fire setting, hydraulic sluicing, leaking, blasting, &c.); and finally, in a subordinate degree, the nature of the mineral itself, as for instance very rich and brittle silver ore, which is liable to be lost in fine particles among the piles of waste, or some kinds of coal which deteriorate by standing too long in the mine after they have been exposed and drained, or clays which become like quicksands in contact with water. Any one of the foregoing conditions may, under certain circumstances, be decisive as to the choice of a method of extraction.—Hydraulic mining is an application of the power of water, under high pressure and at great velocity, to move great masses of material, separate the heavier and more valuable portions, and convey away the lighter waste. (See Gold Mining.) In its modern form it was invented in California about 1852, and is mainly employed in that state. It has been introduced at Iron mountain, Missouri, for the purpose of removing and concentrating the surface ore of that locality. For hydraulic mining, it is necessary to have, besides a deposit suitable to operate upon, a supply of water at a proper altitude, and an escape for the turbid stream, at a level below all the workings. The waste material is thus removed by the current at small cost, while the gold is precipitated to the bottom and caught in crevices, "rifles," &c. As most "hydraulic-gravel" deposits have been accumulated in basins of ancient river channels, they are surrounded by hard rock, called "bed rock" below, and "rim rock" where it comes to the surface at the edge of the deposit. For hydraulic exploitation, the bottom of the deposit must be underrun by a tunnel through the bed rock, and a short shaft from the overlying deposit must be connected with this tunnel. Then the bank may be "hydraulicked" down, and everything except the large boulders sluiced into the shaft and tunnel, and so away to lower grounds. The method of extraction by leaching is peculiar to certain rock-salt mines, in which the mineral is too much mixed with earthy and stony matter to be quarried. Chambers are excavated in the mass, and filled with water, which is allowed to stand until it has extracted from walls and roof sufficient salt to render it a concentrated brine. It is then drawn off, and conveyed in pipes to the boiling works. A layer from the roof of the chamber, disintegrated to a certain distance by this leaching, falls, covering the floor with material from which the salt has been extracted, and leaving a new roof exposed for a repetition of the process. Thus the chambers slowly rise through the mountain. This method is in use at Berchtesgaden in S. E. Bavaria, and Hal-lein in Salzburg.—Other modes of extraction are divided into two classes: those in which the space excavated is filled wholly or partially with waste material, and those in which no such "packing" or "gobbing up" is employed. The former class is subdivided, according to the direction in which the work proceeds, into overhand stoping, underhand stoping, cross stoping, and long-wall working. (The latter method and its modifications, used chiefly in
coal mining, where the seams are not too thick, steep, or variable, may be employed either with or without gobbing up.) The word stope is probably a corruption of step, and refers to the stair-like appearance presented by the face of the excavation. Overhand stoping is conducted as follows: From the level below the ground to be exploited, a "raise" or upward shaft is driven up into the ground, and from this the different "breasts" are driven horizontally on the vein, in one or in both directions. The extraction begins at the bottom, by the excavation of a block having the width of the vein, a height of 4 to 9 ft., and a length of not less than 7 nor more than 30 ft. In this work two sides of the rock are always free: the upright face, toward the central shaft, and the lower horizontal side, over the level. When the breast has been driven far enough, a new workman or set of workmen may begin with a second breast, while the former still continues to advance. Fig. 1, representing the profile of a double stope, shows the order in which the work proceeds. The space behind and below the workmen is filled up with the waste rock, broken from the vein in order to get at the ore, or with rock brought from elsewhere for this special purpose. Openings or "chutes" are left in this, through which the ore can be allowed to fall to the level below, where it is received in cars. This level is usually protected by a roof of stalls and lagging, on which the waste rock is piled, as is shown in fig. 2; or a portion of the vein is left standing over the level, as a protection. The workmen stand on the waste rock, and stoping goes on in the manner indicated, until the whole of the valuable mineral between the bottom level and the one next above (say 60 to 100 ft., measured on the dip of the vein) has been extracted. Of course, by starting stopes at different points on the lower level, within the limits of the mining claim, or the body of valuable ore, more men can be set at work. But the regular productiveness of a mine is not susceptible of indefinite increase in this way. The maximum rate of exploitation which can be maintained until the mine is entirely exhausted, depends upon the rate at which the shafts or shafts can be sunk and new levels opened at greater depths. The too rapid exhaustion of one level would necessitate a suspension of active extraction while the next level below was in course of preparation; and in this work of sinking shafts and running drifts (sometimes called the "dead work" of the mine) it is not possible to multiply the number of men, so as to secure more rapid progress. Only so many men can be accommodated at the bottom of a shaft or the end of a drift; and when their effectiveness has been raised to the highest point by selecting good workmen, dividing them into three "shifts" or gangs, working eight hours each in turn, employing the most suitable tools and explosives, and, if circumstances are favorable, drills operated by steam or compressed air, the limit of practicable progress has been reached; and this determines the normal productiveness of the mine. Driving the stopes faster than the dead work is "robbing" the mine. Underhand stoping is the reverse of the method just described. Here the stopes begin from the level above, and may be commenced (if the presence of water is not too troublesome) before any lower level has been
opened. The ore has to be hoisted, and the waste rock to be lifted by hand and packed on stalls behind the miner, as shown in fig. 3. This system permits an earlier beginning of extraction, and gives the workman a firm footing on the sold vein and an easier and safer direction of working (viz., downward instead of upward). Moreover, there is less chance of losing small pieces of rich ore, which in overhand stoping get into the waste rock under foot and cannot be recovered. But overhand stoping has two great advantages: first, the convenience of rolling and dropping rock and ore, instead of hoisting them; and second, the saving of timber, which in most mining districts soon becomes expensive. The great amount of timber used in an underhand stope is not merely lost; it may give rise by its decay to slides in the packing, or the necessity of expensive repairs to prevent them. Both overhand and underhand stoping are variously modified, as for instance in their application to any thick vein in which cross stoping is not desirable. In such cases, the vein is worked in successive layers or zones, parallel with the walls, each layer beginning with that on the foot wall, being stope out by itself, as a separate vein; 12 ft. is usually as great a thickness as can be stope at one time with safety or convenience. Cross stoping is common in working thick veins. In this method, the vein material is removed in layers, not parallel with the walls, but extending from the foot to the hanging wall; and in each layer the exploitation takes place by driving breasts across the vein, leaving pillars between them; supporting the roof of the breast, 6 to 12 ft. wide, with timbers until

waste rock. A cross layer of the vein, 6 or 7 ft. in vertical height, having been thus removed and the space packed, the operation is repeated with the layer next above. Fig. 4 shows this method by a vertical cross section. It is employed at the quicksilver mine of Idiria, Carniola, and in various modifications at the zinc mines near Aix; the coal mines of Le Creuzot and St. Etienne, in France, the mines of roofing slate near the Rhine, and the lignite mines in Lower Styria. Long-wall working is employed on nearly horizontal deposits, usually coal beds. It may be classed as retreating or advancing, according to whether the extraction begins at the borders of the field or section of the bed to be worked, and retreats toward the main shaft, or begins at the shaft and advances toward the limits. In the latter case roadways are kept through the ground already worked out. Varieties of this method are employed in the copper schist beds of Mansfield, and in many foreign coal mines.

The methods of extraction without packing are: those in which the roof or hanging wall is supported by timbering, masonry, or pillars of the original material, left standing until the workings are to be abandoned; and those in which the roof is allowed to come down immediately after extraction. In the mines of the Comstock vein in Nevada, the spaces are kept open with elaborate timbering, framed as for immense houses. This is a great expense, besides being a source of loss and danger in case of fire. A conflagration in the Yellow Jacket, Kentuck, and Crown Point mines on that lode, which began April 7, 1869, not only cost many lives, but continued to burn, from 600 to 900 ft. underground, for many months, being sustained by the great quantity of dry timber in the stopes.—The system of extraction by breasts or chambers and pillars is practised chiefly in coal mining. It is wasteful of coal, since the pillars of that material left standing are but partially recovered by "robbing," when the breasts are worked out. It is estimated that from 30 to 40 per cent. of the coal in the anthracite mines of Pennsylvania is thus lost.—To the department of extraction belong also the various methods of transporting workmen and material. Where an adit or a slope of gentle inclination leads to the underground workings, the ore and rock are brought out in cars or waggons. For horizontal transportation men or boys, horses, mules, stationary engines, and locomotives are employed. Hoisting through shafts is performed by windlass, horse whim, or water or steam power. When the material extracted has to be lowered, as for instance to deliver it from breasts or stopes to the main roads of transportation underground, or from the shaft or adit mouth to a loading place at a lower level, gravity tramways may be employed, on which the loaded cars, descending, pull up the empty ones. The entrance and exit of workmen through shafts is effected by ladders or stairs, or by lowering

Fig. 4.—Cross Stoping.
and hoisting them in cars, buckets, or cages, or by means of an ingenious arrangement called the man machine or Fahrkunst. Whatever method is adopted, every mine should be provided with ladders in good repair, since other means may fail at a critical moment. In its simplest form, the fahrkunst is a continuous piece of wood, iron, or wire rope, extending from the top to the bottom of the shaft, and provided at regular intervals (8 to 24 ft.) with small platforms, upon which a miner can stand. This frame is so placed in the shaft, and supported by counter weights (and, in inclined shafts, friction rollers), that a regular reciprocating motion, like that of the pumping rods, can be imparted to it. The machinery is so arranged that the stroke is exactly half as long as the distance between the platforms on the fahrkunst, and at the end of the stroke in each direction there is an instant’s pause. During this instant the miner can step from the machine upon a fixed platform in the side of the shaft. As the fahrkunst is kept constantly running, a miner wishing to ascend by means of it has only to step upon it as it begins an upward stroke, step off at the end of that stroke, wait until the down stroke brings opposite to him the platform next above, then step upon that, and be carried another lift higher. At the same time, another miner may descend upon the same machine, by stepping on for the down stroke, and waiting during the up stroke. The double fahrkunst has two such frames or rods, running reciprocally side by side; and here the miner steps across from one to the other, always finding opposite to him, as the platform on which he stands pauses in its movement up or down, a platform on the other frame, just about to commence its movement in the same direction. The moving platforms are usually small, holding but one person conveniently. When two miners pass each other, one steps upon a ladder placed between the two frames. In Belgium the moving platforms are so large as to fill the whole shaft, and take several workmen at a time. The rate of working may be seen from the following statement, calculated for a shaft of 800 ft.:

The Belgian machine is here assumed to be carrying four men on each platform. On ladders one man usually descends 800 ft. in about 30 m., and ascends in an hour. The time allowed for 500 men is about 2½ hours to descend and 5 hours to ascend. The waste of strength involved is also to be considered. When miners are hoisted in the cages, the average velocity being about 15 ft. per second, and the average load four men, about 3½ hours are required to lower or raise 500 men in a double vertical shaft of 800 ft.; or when the load is six men, 2½ hours. At the Comstock mines, Nevada, 12 men descend at once, at a rate varying from 400 to 600 ft. per minute. Some of these mines are more than 1,600 ft. deep. IV. PROTECTION OF THE WORKS AND WORKMEN. Arrangements for the protection of the miners and works include timber or other supports, ventilation, and drainage. Shafts and permanent ways are carefully protected, if necessary, with stout timbering, masonry, or even cast-iron linings. Pillars of rock left standing, piles of waste material packed in the empty spaces, and posts, stulls, lagging, &c., suffice for stopes. In some mines the temporary supports are iron columns, or even screw-jacks, while escaping air is removed without damage and used again. Ventilation is necessary to remove explosive and inflammable gases (carburetted and sulphuretted hydrogen and carbonic oxide, which are also poisonous), and simply poisonous gases, such as sulphurous acid, carbonic acid, and quicksilver or arsenic vapors. Natural ventilation is secured by having two openings to the mine, at one of which (called the intake or downcast) fresh air enters, while the foul air escapes at the other (upcast). The difference in altitude between these openings, and the difference in temperature between the entering and the escaping air, determine the strength of the natural ventilation. It is likely in temperate climates that the air in the mine will be warmer in winter and cooler in summer than that outside. Hence the draft will be in winter out through the highest opening, and in summer the reverse, while periods of stagnation will occur in spring and autumn. The natural draft may be assisted by wise choice of the localities for the openings, or by use of weather caps and chimneys over the upcast; but these aids are not effective except where the intake is an adit. Artificial ventilation is effected by increasing the difference of temperature between the entering and the escaping air, so as to render the currents comparatively independent of the weather, or by increasing mechanically the difference in density. In the first class of instances, either the escaping air is warmed, or the entering air is cooled; in the second class, either the air entering is warmed by suction, or the entering air is condensed by blowing. The escaping current may be warmed by connecting the upcast with the chimney of a steam boiler above ground, or with a special furnace above ground, or by means of a furnace in the shaft, or near the bottom of it, or by introducing steam jets into the shaft. The jets have a mechanical as well as a thermal effect; but the total effect per pound of coal consumed is less than that of the furnace. The cooling of an entering current of air is sometimes effected by allowing water to fall into the downcast, and is also an incidental effect of the water
blow or hydraulic bellows, a simple contrivance by which a falling stream carries a draft of air with it into a receiver, where the air is disengaged from the water, and forced, under a pressure due to the water column, into the mine. Ventilating machines (exhausting or blowing machines) are used almost exclusively in coal mines, where a great excess of air, to dilute injurious gases, is a vital necessity. These ventilators are either reciprocal (pumps) or rotary (fans). The latter are generally employed, and for extensive ventilation the exhausting fans are usually preferred to the blowers. One of the most effective fans, Guibal’s, gives, with a diameter of 14-94 ft. and 8 arms revolving 134 times per minute, a current of 929 cubic feet of air per second. The distribution of the air currents through the mine, so as to bring fresh air to the workmen, and remove all foul gases to the upcast, is very important, and requires a system of air courses, doors, &c. Portable lights in minning are torches, candles, and oil safety lamps. (See Lamp.) Stationary lights are also employed (lanterns with oil or petroleum, gas light, and various electric lights) for illuminating permanent roadways, landings, &c. The drainage of mines is effected by natural means (through adits) or by means of pumps or buckets. These are sometimes operated by hand or horse power or wind, more frequently by hydraulic engines, and most frequently by steam.

V. MINING LAWS AND SCHOOLS. The inalienable right of the sovereign to the metals in the soil is an ancient doctrine, particularly with regard to the precious metals, but is gradually passing away in civilized countries, the governments of which are selling the “mineral rights” which they have hitherto farmed out or operated directly for the revenues of the state. A police supervision, in the interest of public safety and of political economy, is usually maintained. The laws of European states regulate minutely the privileges granted to miners, and their relations to the government and to the proprietors of the soil. In England and the United States, the title to the minerals beneath the surface usually goes with the ownership of the land, but may be disposed of by sale or lease separately. Gold and silver mines were excepted in Great Britain up to the time of William and Mary, being obliged to pay a royalty to the crown. On the public lands of the United States, citizens are allowed to mine without royalty, according to the local regulations established by state and territorial legislation and by the citizens in each district, subject to the general mining laws passed by congress, which fix as the conditions of the possessory title or license a reasonably recorded claim, and the performance of a certain amount of work annually. A complete title, covering a surface tract, and the right to the mineral veins having their outcrops or apexes within the vertical planes bounding the said tract, together with the right to follow such veins in depth, though they may extend under the surface of adjoining tracts, may be obtained after survey and advertisement, by purchase from the United States, at the rate of $5 per acre of surface patented. The mining law is administered, like the agricultural land laws, by the commissioner of the general land office at Washington. In most civilized countries statistics are compiled annually by the government, showing the production of mines and metallurgical works. In the United States this is done imperfectly in the decennial census, and has been done since 1866 for the states and territories west of the Rocky mountains, with particular reference to the gold and silver product, by a special commissioner of the treasury department. (For statistics, see the articles on the different metals and countries.) Regulations to secure safety of miners, and to determine the rights of mining operators toward each other and toward land owners, are made by the individual states and territories. In European countries schools have long existed for training engineers and metallurgists for this industry. Among the most celebrated are the mining academies of Freiberg in Saxony, Clausthal in the Hartz, Schemnitz in Hungary, Leoben in Styria, the academy at Berlin, the école des mines at Paris, and the royal school of mines in London. Much attention has of late been given to this subject in the United States, and the following institutions give special instruction in these branches: the school of mines of Columbia college, New York; the Rensselaer polytechnic institute, Troy, N. Y.; the Purdue scientific department of Lafayette college, Easton, Pa.; the Sheffield scientific school of Yale college, New Haven, Conn.; the Massachusetts institute of technology, Boston, Mass.; the school of mining and practical geology of Harvard university, Cambridge, Mass.; the Stevens institute of technology, Hoboken, N. J.; the school of mining and metallurgy of Lehigh university, Bethlehem, Pa.; the scientific department of the university of Pennsylvania, Philadelphia; the school of mines at Rolla, Mo.; the polytechnic department of Washington university, St. Louis, Mo.; the school of mines at Golden City, Colorado; and the university of California, Berkeley, Cal.

MINER, a S. E. county of Dakota, recently formed, and not included in the census of 1870; area, 432 sq. m. It is intersected in the W. part by the Dakota river. The surface consists of gently undulating prairies.

MINER, Alonso Ames, an American clergyman, born in Lempster, N. H., Aug. 17, 1814. He was principal of the scientific and military academy of Unity, N. H., from 1835 to 1839, when he was ordained a minister of the Universalist church, was settled at Methuen, Mass., and in 1842 took charge of the second Universalist church in Lowell. In 1848 he was associate pastor, and in 1852 pastor of the second Universalist church in Boston. He was presi-
MINER DEPOSITS

MINER, Thomas, an American physician, born in Middletown, Conn., Oct. 15, 1777, died in Worcester, Mass., April 23, 1841. He graduated at Yale college in 1796. The next six years he passed in teaching, and in the study of law, which he abandoned for medicine, and in 1807 he commenced practice at Middletown. About 1809 a malignant epidemic, called spotted fever, prevailed in the Connecticut valley, for which he pursued a new mode of treatment, making careful notes of his cases. In 1828 he published, with Dr. William Tully, "Essays on Fevers and other Subjects," and in 1835 a treatise on "Typhus Syncopalis." His autobiography appeared in the "New Englander," vol. II, p. 19.

MINERAL, a N. E. county of West Virginia, separated from Maryland by the North branch of the Potomac river, and intersected by Patterson creek and other streams; area, about 550 sq. m.; pop. in 1870, 6,362, of whom 378 were colored. It is crossed by several mountain ridges, between which lie picturesque and fertile valleys. The Baltimore and Ohio railroad runs along the N. and W. border. The chief productions in 1870 were 50,915 bushels of wheat, 71,885 of Indian corn, 29,931 of oats, 8,891 of potatoes, 23,406 lbs. of wool, 52,078 of butter, and 5,104 tons of hay. There were 1,333 horses, 5,173 cattle, 6,429 sheep, and 2,563 swine. Capital, New Creek.

MINERAL DEPOSITS. The useful minerals occur in a variety of forms and conditions, and the deposits which are composed of or include them may be classified into superficial, stratified, and unstratified deposits. I. SUPERFICIAL DEPOSITS. In these, the materials are yet unconsolidated, and have been washed down from cliffs and mountain slopes composed of rocks that contain metals, ores, and gems, either in veins or irregularly disseminated. This category includes the gold of the surface deposits associated with the gold-bearing rocks of California, Colorado, Australia, the Ural mountains, &c.; the platinum of Oregon and Siberia; the "stream tin" of Cornwall, Banca, Australia, and Durango; the diamonds of Golconda, Brazil, and South Africa; and the rubies and sapphires of Ceylon. From such deposits all the platinum, all the diamonds, and probably nine tenths of all the gold in use have been procured. The working of these deposits constitutes the simplest form of mining, viz., washing with water. The minerals obtained from them are usually distributed very sparsely through the rocks in which they primarily occur; and as in the course of ages, by frost, sun, rain, and ice, these rocks have been comminuted and washed away, the metals and precious stones they contain have been sorted and concentrated by the action of water, so that in many instances they are gathered with little labor. By the Spaniards, the superficial deposits containing gold are called placeras, and the working of these deposits has come to be generally termed placer mining.

II. STRATIFIED DEPOSITS. The useful minerals sometimes form entire strata, such as beds of coal and iron ore; and they are sometimes disseminated through sedimentary rocks of which they form a larger or smaller part. In this latter category are included the clay-iron-stone of the coal measures, and iron ores of the old red sandstone. They are found either in the triassic sandstones of New Mexico, and in the sandstones and conglomerates of Lake Superior. III. UNSTRATIFIED DEPOSITS. 1. Eruptive Masses. Formerly most of the deposits of crystallized iron ore (magnetite and specular iron) were supposed to be eruptive. We have learned now that they are for the most part only stratified deposits very much disturbed and metamorphosed. Such is certainly the character of the iron ores of Missouri, Lake Superior, and the Alleghany belt, all of which may be shown to be simply changed and disturbed beds of iron ore, once deposited in nearly horizontal sheets. The famous deposits of iron ore of the island of Elba and of Nizhni Tagilsk in Russia are still believed to be eruptive, but it is probable that they will hereafter be shown to belong to the same category with our American ores, wallite iron ores. Iron is a common ingredient of volcanic rocks, and in some instances the quantity contained in them is so great that they may be termed low-grade iron ores; but such cases are extremely rare, and it is very doubtful whether there are any deposits of metals or ores of economic value which can properly be regarded as eruptive masses. It is scarcely necessary to say that the great deposits of metallic copper found on Lake Superior, and supposed at one time to be the result of subterranean fusion, are now clearly shown to be the products of chemical precipitation, and to have been deposited much as copper is precipitated in the electrolysis process. 2. Minerals disseminated through Eruptive Rocks. Of this class of deposits, magnetic iron contained in volcanic rocks and the copper in the amygdaloids of Lake Superior may be taken as examples. In Japan the iron derived from decomposing volcanic rocks is collected and used, and large quantities of copper are obtained from the so-called melaphyre of the Portage Lake district on Lake Superior; but as a general rule igneous rocks are very barren in useful minerals. 3. Contact Deposits. The plane of junction between two rocks of different kinds, such as igneous and sedimentary rocks, is frequently the place where metals or ores have accumulated and formed concretions, strings, or sheets. Examples of this may be seen in the deposits of copper at the junction of the trap and ash.
bed and of the trap and sandstone in the Lake Superior series.—4. Impregnations. In certain cases metalliferous minerals are found diffused irregularly through rocky masses, the deposits of ore having no definite boundaries or any regularity of structure, and appearing as though the rock had soaked up or absorbed the minerals, as water saturates a sponge. Such accumulations of ore are called impregnations. The deposits of mercury exhibit this character in a marked degree.—5. Fahlbands. This name has been given to a peculiar kind of deposit where the ore is sparingly diffused through certain layers, which are prone to disintegrate and are more fahl (i. e., foul or rotten) than the associated strata. Typical examples of this kind of deposit may be seen in the silver mines of Kongsherg, Norway, but they are not common elsewhere. Usually the fahlbands are only rich enough for working where cut by veins.—6. Stockwork. Where the masses of metalliferous rock are penetrated in every direction by threads or strings of ore, so that the whole must be taken out together, it is called a stockwork. Such deposits occur locally in many mines, but rarely to such a degree as to give character to the mining operations. The copper mines of Lake Superior, and the silver mines of Norway, Freiberg (Saxony), and Nevada, all furnish examples of stockwork.—7. Mineral Veins. These are usually sheets of mineral matter, of greater or less lateral and vertical extent. They have been divided into three principal varieties, which are generally well marked, but which sometimes blend in such a way as not to be easily separated. These varieties of mineral veins are known as gash veins, segregated veins, and fissure veins. a. Gash Veins. These are such as are confined to a single stratum or formation, and hence opening into caves or chambers lined with "mineral." These gash veins have apparently been formed by the shrinkage of the Galena limestone after its deposition. Subsequently the shrinkage cracks were enlarged by the dissolving away of their walls, and were lined with galena, deposited from a solution which exuded from the adjacent rocks. Similar veins also containing galena occur in Missouri, but in a formation somewhat more ancient, the magnesian limestone, supposed to be the equivalent of the calciferous sand rock of New York. The fact that these gash veins are limited to a single formation has been amply proved by numerous shafts sunk in the hope of finding the ore at a greater depth, all of which have been failures. b. Segregated Veins.

![Fig. 2.—Horizontal Gash Veins or Floors of Lead in Galena Limestone. a. Crevice with pocket opening. b. Crevice openings.](image)

![Fig. 3.—Segregated Veins of Auriferous Quartz in Gneiss.](image)

These are usually lenticular sheets of ore-bearing mineral, which are conformable to the bedding of the associated rocks, that is, are interposed between the layers of such rocks. Segregated veins always occur in metamorphic rocks, and are usually inclined at a high angle with the horizon. They are called segregated veins because they are supposed to have been formed in the process of metamorphism by the separation or withdrawal of the materials which compose them from the adjacent strata, and their concentration along certain lines. Segregated veins are limited both laterally and vertically. They rarely exhibit anything of the banded structure which characterizes fissure veins, are chiefly composed of quartz, and form the great repositories of gold. All the quartz veins, which are so common in the
granitoid rocks of the Alleghanies, belong to this class and carry more or less gold. Iron pyrites is an almost constant associate of gold in segregated veins, sometimes being present in great quantities. Copper is also frequently contained in them, and in less quantity nickel. Though segregated veins have generally no great lateral or vertical extent, they sometimes attain a thickness of 20 or 30 ft., and have a length on the surface of a mile or more. The Pine Tree and Josephine lodes on the Mariposa estate in California have a thickness of 4 to 12 ft., and are said to be traceable for some miles. These are reported to be segregated veins lying in sheets of slate rock of Jurassic age. Segregated veins are generally of much more mod-
est dimensions, and are seen to lie alternately or en échelon along the outcrops of the con-
taining rocks. In Australia the gold-bearing segregated veins are commonly termed "quartz reefs," having doubtless derived their name from the fact that, being harder than the asso-
ciated rocks and yielding less readily to atmos-
pheric erosion, they are left in relief, some-
times projecting in ridges above the surface. e. Fissure Veins. These are of indefinite ex-
tent, laterally and vertically. They have been formed by volcanic or earthquake action, by which the rocks have been fractured and dis-
placed. In all cases where an important crack or fissure is made by subterranean upheaval, either by the slipping in of wedges of rock or by the shifting of the sides of the fissure so that their irregularities fail to match, the walls are prevented from returning to their original positions, and an irregular open crevice is pro-
duced. When subsequently filled by foreign matter containing metals or ores, such a fissure becomes a fissure vein. In some instances the fracture of the rocks has considerable regu-
larity, and the fissure may be of uniform width for several hundred feet in either direction. More generally, and especially where a fracture

is attended with displacement, the fissure is of very unequal width; the vein matter has in places a thickness of many feet, while at other points, where the projecting walls approach or come in contact, the vein becomes very thin and may be quite pinched out. From their mode of formation fissure veins are without definite limits horizontally or vertically. They may frequently be traced for miles upon the surface, and their limits in depth are rarely reached. Hence they hold more extensive and continuous deposits of ore than any other kind of mineral veins, and constitute the most trust-
worthy bases for mining operations. Fissure veins frequently exhibit a banded structure in the materials which compose them, and this forms one of their most striking characteristics. This feature is produced by the deposi-
tion on their walls of successive layers of dif-
ferent minerals, such as quartz, fluor spar, calc spar, copper or iron pyrites, blende, galena, and baryta. These layers often correspond on either side of the central line, showing that the deposition of the different sheets took place simultaneously on both walls. Some-
times a fissure vein exhibits a double or triple

series of bands, showing that after being filled with ores it was again opened and a new fissure formed, and then this was filled in the same way as the first. The quartz which con-
stitutes a large part of the material composing fissure veins frequently shows a "comby" structure, due to the formation of crystals which shoot out from the walls and interlock

where they meet. Another common feature in fissure veins is the "flucan" or "selvege," a sheet of clay which lines either wall and causes the vein matter to cleave off readily. This flucan seems to be due partly to the attrition of the sides when moved with im-
mense force upon each other, and partly to the action on the walls of chemical solutions filling the fissure. The sides and sometimes the in-
terior of fissure veins generally show polished and vertically striated surfaces ("slickensides"). These are undoubtedly produced by the fric-
tion of the walls on each other or on the ma-
terial composing the vein. As will be inferred from what has been said of their mode of formation, fissure veins cut indiscriminately through all kinds of rock. They frequently traverse stratified rocks across their line of

deposits. 579
deposition and outcrop, and are then called "cross-cut" veins, to distinguish them from those that are more or less accordant with the stratification. The materials composing fissure veins are very varied; indeed, it may be said that nearly all the minerals known are found in them. Quartz is a conspicuous ingredient in fissure veins, but sulphate of baryta, calc spar, and fluor spar sometimes form almost the entire mass of the veinstone.—The ores which are contained in fissure veins, like the earthy minerals, are widely varied. Silver, copper, lead, tin, zinc, antimony, iron, and more rarely many other metals are found in them. Gold is less common in fissure than in segregated veins, and it is almost never the sole object of search in their exploitation; but it is a recognized constituent in the veins worked in Cornwall, and in the silver ores obtained from some of the mines in Idaho, Nevada, Mexico, and South America. Silver may be regarded as the most valuable constituent of fissure veins, and all the great silver mines of the world are worked in veins of this character. The Comstock lode, near Virginia City in Nevada, is a true fissure vein, and perhaps the largest and richest known. It has been traced on the surface for several miles, and has been worked to the depth of 1,600 ft. Its normal width is perhaps 200 ft., but in places it expands to 800 ft., though here divided into several veins by great wedges or "horses," split off from the walls. It cuts through syenite and propylite, and evidently marks the line of a great fissure opened by volcanic action. All the silver mines of Nevada belong to the same class with the Comstock, though the other veins are generally of much more moderate dimensions. They are worked in fissure veins which traverse all the varieties of rock found in that region, such as granite, porphyry, trachyte, slate, and limestone. The number of these veins, the disturbed and broken condition of the strata, and the abundance of volcanic rocks in the district, all prove that it has been long the theatre of intense volcanic and earthquake action. In Nevada and Utah some very rich mines have been worked in deposits of ore, of which the true character has been imperfectly understood and very much misjudged. These are the chambers or pockets of ore so characteristic of the White Pine district, Nevada, and that of Little Cottonwood canyon in Utah, the latter including the famous Emma mine. These districts have been the centre of intense mining excitement and scenes of the wildest speculation; of the most unparalleled successes and sudden and complete failures. A large part of this history has been consequent on the peculiar nature of these mineral deposits. In both these districts the ore occurs in limestone, and often in chambers frequently of considerable size. These when first opened were supposed to hold innumerable wealth, but they proved to be of limited extent and were soon worked out. The relations of the ore chambers of White Pine and Little Cottonwood to the silver-bearing fissure veins of Nevada and Utah are not at first sight apparent, and yet they are unquestionably products of the same general cause. The true theory of their deposit is probably this. The "country rock," i.e., the rock enclosing the deposits of ore, unlike that of most of the mining districts of the west, is limestone. Many limestones are soluble in atmospheric water which holds carbonic acid in solution. In some limestone countries the underlying rock is honeycombed by caves and subterranean galleries, forming a system of underground drainage. The table land of Kentucky affords a typical example of such a region, and the Mammoth cave is only one of an immense system of natural sewers, by which the drainage of the surface is effected. If now the Kentucky table land were much disturbed by an earthquake and fissures were opened through the limestone, and these fissures were filled to form mineral veins, then, wherever these fissures communicated with the subterranean chambers and galleries, these would also be filled with vein matter and ore, and a condition of things would be produced similar to what we now find in Utah and Nevada, though on a much grander scale. With this explanation the western pockets and chambers of silver ore are seen to be natural offshoots and appendages of the fissure veins so common in the region where they occur.—The Filling of Mineral Veins. The manner in which the materials composing mineral veins have been deposited has been a matter of much discussion among geologists, and one about which there has been and still is considerable diversity of opinion. The theories which have been advanced to account for the phenomena are briefly as follows. a. The Theory of Injection. This was proposed by the Plutonists, who were prone to ascribe all the great changes on the earth's surface to the action of heat. There are few mineral veins, however, composed of materials which can be regarded as even the possible product of fusion, and most

---

**FIG. 6.—Fissure Vein with Cavity or "Vug" at Centre.**

**a a.** Country rock, **b b.** Heavy spar. **c c.** Calc spar. **d d.** Blende. **e e.** Comby quartz. **f f.** Vug.
of them contain minerals which could never have been formed in the presence of great heat. The veins containing great masses of copper on the south shore of Lake Superior, when first described, were considered as shining examples of the truth of the igneous theory; but the frequent occurrence of masses of native silver in the copper, both metals being distinct and almost chemically pure, prove that these metallic masses could never have been fused together, as in that case they would have formed an alloy. Other evidence has been cited by Prof. Pumpelly which demonstrates that none of the copper veins have been filled by igneous action, but that the materials they contain have been deposited from solution. Trap dikes, which are fissures filled by injected volcanic material, have doubtless suggested the igneous theory of mineral veins; but when they are carefully examined the materials which compose them are found to be quite different in their nature and arrangement from those which form mineral veins. In fact, dikes and veins have only this in common, that they fill similar fissures produced by subterranean violence. b. The Theory of Aqueous Deposition. This theory apparently emanated from the Wernerian school, who regarded water as the great, if not the sole cause of geological phenomena. The advocates of this theory have suggested that fissures have been opened up into seas or other water basins, and that the vein materials have been deposited from water, as limestone and other sedimentary rocks are laid down. A fatal objection to this theory is that we never find the materials composing true fissure veins horizontally stratified as aqueous sediments are, but on the contrary these materials are often deposited vertically against the walls of the fissures. Again, if the vein materials were deposited from reservoirs into which they opened, the bottoms of these reservoirs ought to show similar sheets of matter, whereas nothing of the kind has ever been found. c. Lateralsecretion. According to this theory, the materials of mineral veins have been derived from the adjacent rocks by percolation through the vein walls. If this were true, we should find the contents of veins changing with every stratum through which they pass, whereas in fact the composition of a mineral vein is often nearly identical in all parts of its course, notwithstanding it may pass through a variety of strata. Again, where two systems of veins cut through the same stratum, according to this theory, in that stratum their contents should be similar, whereas we often find them totally diverse. Where two veins cross each other, they are often seen to be of different ages, and to be composed of materials so different that they must have been derived from different sources. The banded structure of fissure veins seems also quite incompatible with this theory, for it is scarcely possible to conceive of the formation of the different layers which compose these veins on the supposition that they have been deposited by exudation from the walls of the fissure, and that the totally distinct minerals composing the inner and newer layers have been transmitted through those first formed. As has been mentioned, in gash veins the cavities are filled or lined with materials derived from the adjacent rocks, but these cases afford an unsatisfactory explanation of the filling of fissure veins, the only ones about which there is any question. d. Sublimation. Most of the minerals, and perhaps all of the metals, can be sublimed at a very high temperature; and some of them, as zinc, arsenic, and mercury, are vaporized at a comparatively low temperature. The fissures about a volcanic crater are frequently lined, sometimes filled, with minerals, some of them ores, which have plainly been driven out from the volcano in a state of vapor. Such cases have led some theorists to suppose that sublimation played an important part in the filling of mineral veins. As has been said, the deposits of mercury have often the character of impregnations, and in some instances at least we have good evidence that mercury is diffused in the form of vapor; but these deposits have certainly very little in common with the distinctly limited, often banded and crystallized matter filling mineral veins, properly so called. Hence this theory is in the main rejected by modern mineralogists. e. Chemical Precipitation. This theory attributes the deposition of mineral matter in veins mainly to precipitation from solution, and this is the view now generally taken by those best informed on the subject. According to this theory, fissures destined to become fissure veins are first filled with water, usually flowing from sources deep in the earth, where, highly heated and under great pressure, it becomes charged with mineral substances. As it approaches the surface and the temperature and pressure are reduced, its powers of solution are diminished, and a large part of the materials it has carried are precipitated on the sides of the channel through which it flows. The abundant and varied deposits made by thermal springs illustrate the sufficiency of this cause. In this view, the banded structure which is exhibited by mineral veins is attributed to changes during the lapse of ages in the nature of the solution, dependent upon some deep-seated cause, such as successive convulsions opening new sources for the supply of material. Sulphur we know is one of the most common constituents of volcanic emanations, and the normal condition of most ores found in veins is that of the sulphide; and we have reason to believe that they are mainly deposited from a hot solution in which sulphur was the most conspicuous ingredient. Highly heated water or steam, containing sulphur, fluorine, and chlorine, would be capable of dissolving most of the minerals with which it came in contact. It would certainly be charged with silica, and if flowing or driven through
rocks containing even minute quantities of silver, gold, lead, iron, copper, or other metal, would gather these materials, and coming toward the surface would precipitate them in the form of sulphides. The replacement of animal and vegetable tissues by mineral matter, which often occurs in their fossilization, affords proof that chemical solution is entirely adequate to produce all the phenomena exhibited in the filling of mineral veins. In petrified wood the vegetable tissue is replaced, particle by particle, by silica, evidently deposited from solution. The sulphides of copper and iron often replace wood in the same way, and this could only take place on a great scale, as it often does, when the rocks were saturated with a solution containing these metals. The formation of geodes, the filling of the cavities of amygdaloids with agate, chalcedony, and zeolites, the sheets and stalactites of iron and lead in the Galena mines, and the stalactites of lime in caves, prove that such solutions are constantly flowing through the rocks beneath us. In some formations and localities molluscan fossils are found completely replaced by galena, pyrites, and blende, the lime of their shells having been carried away and the different ores deposited in its place. In the cavities left by some shells, successive layers of sulphides of lead, iron, and zinc are deposited, showing in miniature almost precisely the phenomena observed in mineral veins. A few general features in mineral veins remain to be noticed. Oftener than otherwise, the mineral veins of any district are seen to belong to one or more systems in which the individual veins have nearly a common bearing and a general similarity of composition. In the mining district of Cornwall, England, there are two principal systems of veins, one running nearly north and south, the other approximately east and west. The latter carry copper and tin, the former chiefly lead and iron. In the lead region of the northern Mississippi there are also two principal systems of veins, which vary somewhat in their bearing, but are generally known as the north and south and east and west courses. In the mining district of Freiberg, Saxony, nine systems of veins are said to have been identified; and in the silver belt extending parallel with the Pacific coast, from Idaho and Nevada to Ophir, which has been almost constantly shaken and shattered by earthquakes, the systems of veins are almost innumerable. In less disturbed regions, like the Mississippi lead district, the courses of the veins coincide with the jointing of the rocks, and thus in many instances exhibit a kind of polarity; that is, one set of joints coincides with or approaches in direction the meridian, while the other is nearly at right angles to this. There is little doubt that the system in the jointing of rocks, and hence in the bearings of mineral veins, often determined by the jointing, has been considerably affected by terrestrial magnetism. It is also probable that this cause has operated to control or influence the deposition of mineral matter in veins. Mr. Fox of England found that the water in the copper mines was a weak solution of salts of copper, and that the galleries filled with this solution were in fact cells of galvanic batteries, from which well marked currents were produced. Solutions similar to these found in old copper mines, but hotter and stronger, have undoubtedly filled most of the fissures now occupied by metalliferous veins. It is easy to see that such cells might generate powerful magneto-electric currents, by which the metals, especially silver and copper, might be precipitated in great quantity, just as they are now precipitated in the electro-plating process.

**Gossans.** Nearly all mineral veins are found to be very much weathered and decomposed along their line of outcrop. The decomposition generally extends down to the permanent water level, below which the ore is in its normal state, and this for the most part is sulphide. When exposed to the action of atmospheric water and air, the sulphides are oxidized, and the whole mass of the veinstone is frequently rendered soft and spongy, and highly colored in various ways. When the vein contains much iron pyrites, this is converted into the hydrated sesquioxide of iron, coloring all the decomposed mass brownish red. From this fact the changed portion of the vein is called in Germany the Eisenhaut, iron hat. In Cornwall the decomposed portion of a mineral vein is called a gossan; and this term has been universally adopted in all mining districts where English is spoken. In the gossans of veins we usually find the sulphides of silver converted into chloride, bromide, iodide, &c., with many sprigs and masses of native silver. Copper ore, generally the sulphide of copper and iron in its normal state, is converted first into red or black oxide, and then into malachite, azurite, and chrysocolla, the carbonates and silicate of copper. Locally, when affected by saline solutions in South America, the copper mite, the chloride, is produced. All these secondary forms of ores are more easily treated than the sulphide, and the gossan which contains them is usually loose and easily excavated. This portion of a mineral vein is therefore much more easily and cheaply worked than that which lies below the permanent water level. Hence the first workings of mineral veins are frequently highly remunerative, while the cost of deeper excavations in harder rock, and the expense of treating the more intractable sulphides, cause subsequent operations below the water level to result in disappointment. In many mining districts, like those of the southern Alleghanies in the United States and of Sonora in Mexico, the first comers, by working the gossans, were able practically to skim the cream of the mineral veins, carrying off great profits, and leaving to the second generation an inheritance of which the value is often worse than doubtful.
MINERALOGY, the science which treats of the composition, structure, formation, and classification of minerals. The term therefore covers both descriptive mineralogy and mineralogy, which is the study of the laws in accordance with which minerals are formed. All objects in nature consist of certain substances recognized as elementary bodies, which exist either as individual wholes, when they are called native elements, or combined with one another. All the native elements belong to the mineral kingdom, and also all combinations of elements which do not pass through the cycle of change called growth. The combinations of the elements which man produces all belong to the mineral kingdom, since he is not able to impart the principle of growth. When his products are homogeneous in composition and structure, they are, strictly speaking, artificial minerals; and chemists are able to produce a great number of the combinations found in nature. The study of minerals presents three general classes of characteristics: chemical composition, crystalline form, and physical properties. 1. CHEMISTRY OF MINERALS. In combining, the elements exhibit a strict subjection to certain fixed modes of union, and these modes are the laws of chemical combination, which are still very imperfectly understood. Chemists recognize two kinds of units. The smallest possible particle of an elementary substance is called an atom. These atoms seem to exist in a state of polarity, and to possess electrical attraction and repulsion, by means of which they effect union with each other and with the atoms of other elements. They are not always able to exist by themselves, but the atoms of some elements act in pairs or triplets, or in some other degree of union. This combination of atoms, whether composed of the atoms of more than one element, or of one only, is called a molecule. Molecules have the power of cohesion, and by their aggregation masses of matter are formed. Both of these units are used in mineralogy. Every true mineral is formed of innumerable molecules cohering together, and each of these molecules is composed of one or more atoms of each element contained in the mineral, according to the proportion in which it is present. While there is an unending diversity in the composition of minerals, it is found that the elements always unite in some simple proportion or ratio. Three kinds of ratios are used in mineralogy. The percentage ratio is the one in which analyses are always published. It assumes the weight of each molecule to be 100, and expresses the proportionate quantity of each element in the molecule in parts of 100. Lime, for instance, contains 71-43 per cent. of calcium and 28-57 per cent. of oxygen. The atomic ratio is the ratio between the number of atoms of each element in the molecule, and is obtained by simply dividing the percentage ratio of each element by its atomic weight. When the symbol of a mineral is given, the atomic ratio may be ascertained by simple inspection of the symbol. In lime, the symbol of which is CaO, the molecule is composed of 1 calcium and 1 oxygen, and the atomic ratio is therefore 1 : 1. In andalusite, which is composed of Al₂O₃Si, the atomic ratio of the aluminum, oxygen, and silicon is 2 : 5 : 1; while if the oxygen is divided between the aluminum and silicon, the compound will be considered as formed of two radicals, alumina and silicea, and the atomic ratio of these will be 1 : 1, there being one of each. The third method of comparison is the oxygen ratio; it consists in a comparison of the number of oxygen atoms contained in the different oxygen compounds present. In andalusite, for instance, the alumina has three oxy atoms and the silicate two. The O ratio is therefore 3 : 2. The explanations so far given relate to the old method of writing chemical symbols. The new chemistry reaches the same results by a different mode of reasoning. Every binary compound consists of one positive and one negative element. Every ternary compound consists of one positive element, a second which is negative to the first but positive to the third, and finally a third which is negative to both the others. The number of negative atoms in a binary compound is found to vary with the different elements, each element having the power to fix a certain number of atoms of a more negative element; this power is called its atomicity or quantivalence. All of the stable binary compounds of hydrogen are found to contain one atom of hydrogen and one of the other element, whatever it is; and hydrogen is therefore taken as the standard. By comparing the other elements with it, it is found that 23 of them have a combining power equal either to 1, 3, or 5 hydrogen atoms; and these are therefore called univalent, trivalent, or quinquivalent. These never form stable saturated compounds with any even number of negative univalent atoms, and they are therefore called perissads, from the Greek word for odd numbers. The remaining 40 elements have a combining power which is 2, 4, or 6 times that of hydrogen, and they are therefore bivalent, quadrivalent, and sextivalent. These form the general class of artiads, and are never saturated when combined with an odd number of negative univalent atoms. The highest possible combining power of an element is called its atomicity, but this is not always the most common form of its occurrence, which is often one of the lower degrees; this prevalent form is its quantivalence. The oxygen ratio, although it was used with the best results in mineralogy long before the new chemical theories were established, is nothing more than the expression of the relative quantivalence of the different elements contained in a mineral. Oxygen is in all cases a negative element, and the number of its atoms which are combined with one atom of any other element, taken in connection with
the doubled atomic weights of the new chemistry, indicates the relative quantivalence of the combined elements. The change of ideas in regard to the modes of combination has necessarily produced a new mode of writing the symbols of minerals. Under the dualistic theory, when every ternary oxygen compound was supposed to consist of one oxide acting the part of a base and another oxide acting the part of an acid, the formula was constructed by writing the two compounds one after the other, as RO,SiO₂ or R₂O₆SiO₃, in which it stands for any basic element. The new system endeavors to make its formulas rational, that is, to construct them in such a way as to embody the present views in regard to chemical combination. The elements are divided into three classes: 1, the basic, which are positive to those following; 2, the acidic, which are negative to the foregoing, but positive to the third class; 3, the acidic, which are negative to both the first and second. In a ternary compound which consists of one element from each of these classes, the acidic element is supposed to act as a bond between the other two, and for that reason it is placed in the middle, the basic being written first, the acidic next, and the acidic last; as Mg₄O₄Si. It has been explained that one atom of each element has the power of uniting to itself a certain number of atoms (from one to six) of hydrogen or other univalent element; and just as the ancients provided the elements with hooks by which they caught hold of each other, so modern chemists express the quantivalence of an element by saying that it has a certain number of bonds of attraction. Magnesium has a quantivalence of 2, and as there are two molecules of it in the above symbol, the total number of its bonds in the formula just given is four. Silicon has a quantivalence of 4, so that the oxygen has four bonds to satisfy on each side, or eight in all. As its quantivalence is 2, the four molecules present in the compound have a total uniting power of eight. But the whole of the oxygen does not always play the part of a uniting element only. The number of molecules of uniting oxygen (or other acidic element) is equal to the number of bonds of attraction in the basic or acidic element, according as the former or the latter has the smaller number. In the symbol given above, the number of oxygen bonds is just sufficient to satisfy those of the other elements, but in the symbol Mg₄O₄Si there are two bonds on one side of the oxygen and four on the other. In this case part of the oxygen is considered to be combined with that element which has the greater number of bonds to be satisfied. When this is the acidic element, as in the present case, the symbol is written with the acidic element at the left side; as SiO₂O₄Mg. If the basic element had possessed the greater quantivalence, that element would have been written at the left; as in the symbol for chondrodite, Mg₄O₂(O,F)₄\|Sii. Thus the symbols are made to express the mineralogist's views of the constitution of minerals.—Replacement. Minerals in their chemical composition are elementary, binary, ternary, quaternary, &c., according as the number of molecules of which they are composed is one, two, three, or four, &c. This, however, does not indicate the possible number of elements present, since each molecule may contain several elements. Enstatite, which is composed of magnesium, oxygen, and silicon, is a ternary; and diaspole, which has magnesium, iron, calcium, oxygen, and silicon in its composition, is also only a ternary, since the first three elements form only one basic molecule. In this case each element in the basic molecule is a dyad (that is, it has a quantivalence of 2), and it may not seem strange that, with equal powers of combination, they should be able to replace each other. But other minerals are found which contain elements of the most diverse degrees of quantivalence, and therefore in the most diverse states of combination. Zircon sometimes contains a protoxide, a sesquioxide, and a deutoxide. The law under which these diverse combinations are brought harmoniously together is that "the replacing power of the elements is in proportion to their combining power." Thus one molecule of an element which has four bonds of attraction, like tin, is able to replace two molecules of an element which has only two bonds of attraction, like calcium. In stannite, which is a sulphide of copper, tin, and iron, the proportions of these elements are 2:1:1. Copper, which is bivalent, requires two atoms to occupy toward sulphur the same relation which one atom of tin and iron has. The proportion in which any element in any state of combination must replace other elements in a different state may be ascertained from the following table, in which the line A contains the several oxides that are known, the line B contains the same oxides reduced to a common oxygen standard (O=1), and the line C represents the proportions in which the bases are interchangeably. The different states are represented by Greek letters in order to avoid confusing fractions. Thus the beta state is sesquioxide and the gamma state is the deutoxide. R is used to represent any basic element, and it is to be remembered that, though only oxides are represented here, the rule holds good for all negative elements.

A: RO, R₂O₃, R₃O₄, R₄O₅, R₅O₆, R₆O₇
B: RO, R₂O₃, R₃O₄, R₄O₅, R₅O₆, R₆O₇

Any element in the tritoxide state (εR) therefore requires but one basic atom to replace three basic atoms of an element in the protoxide or alpha state. The method of writing the symbol of a mineral which has suffered such substitution may be seen from the symbols of magnetite and franklinite. The former contains iron in the alpha and in the beta state
of combination with oxygen. Its symbol is \((\frac{1}{6}Fe + \frac{1}{3}FeO)O\), and it is therefore a binary compound. In franklinite the \(\alpha Fe\) is partially replaced by zine and manganese in the alpha state, and the \(\beta Fe\) is partially replaced by manganese in the beta state. The symbol then becomes \(\{(\frac{1}{6}Zn, Fe, Mn) + \frac{1}{3}Fe, \beta Mn\}\)O. The \(\alpha\) is not written, the protoxide state being understood when no other is mentioned. The effect of the law of replacement is, that whatever kinds of binaries may be united in the mineral, the oxygen ratio is unchanged, and the use of this ratio is therefore continued in mineralogies, though the oxygen is no longer considered to be divided between the basic and acidic elements. It expresses the quantivalence of these elements, and this is held to be one of the most essential characteristics of a mineral species. While the power of replacement has greatly increased the number of mineral species by presenting us with compounds which vary too much to be described under one name, it has lessened the number of groups in an equally marked degree, since the substitution often takes place without materially altering the other characters. Thus tourmaline, which is a ternary, sometimes contains 12 elements, and the basic molecule always contains elements in the alpha, beta, and gamma states. Their proportions vary so much that five classes have been made in which the O ratio of these three kinds of bases varies between \(4:12:4\) and \(4:56:12\); and yet tourmaline is usually very plainly recognizable and possesses very persistent crystallographic habits.—Classification of the Elements. With the foregoing explanations the following table in which the elements are classified will be understood:

### Classification of the Elements

</table>

The three kinds, basic, acidic, and acidified, are arranged in three series. Each series begins with a section of perissads, or elements with a quantivalence which is 1, 3, or 5, and ends with a section of artiads, or elements which have a quantivalence of 2, 4, or 6, thus bringing together allied elements. The basic artiads comprise two groups, one of protoxides and sesquioxide, and the other of deutoxides. The acidic artiads form a tritoxide and a deutoxide group. It is therefore plain that each group is made up of elements which occur in the same state of combination, or have the same quantivalence, and the groups might with perfect propriety be called the alpha, beta, &c., groups. Each group therefore includes not only its own leading elements, but also the \(a, \beta\), or \(\gamma\), &c., states of other elements; and therefore each group comprises a series of homomorphous (or mutually replaceable) elements.

### II. Crystalline Form

Atoms are supposed to have definite shapes, for the greater number of the mineral species have exact geometrical forms which have been classified in six systems. (See Crystalllography.) The atomic form seems to be different for the different elements; and since the same element is sometimes found crystallized in more than one system, it is supposed that the number of atoms in the molecule influences its shape. Thus the mineral species palladium is the native element of the same name, and crystallizes in the isometric system; while allopalladium, which is also the native element in a pure state, is hexagonal. The theory is that, while the molecule of palladium contains one atom, the molecule of allopalladium contains three atoms of the same substance. The diamond (isometric) and graphite (hexagonal) are both carbon, and form another example of this phenomenon, which is called isomerism. A great many of the compounds are identical in composition, but differ in form. Andalusite, felselite, and cyanite have the same composition, but crystallize in different systems, and have a different hardness and specific gravity; and these differences are ascribed to a more or less condensed molecule, but what the numerical relation of the atoms in these molecules is, has not been established. It has, however, been suggested that the forms assumed may be due to the number of negative atoms in the molecule. Thus protoxides may assume isometric forms, deutoxides may be tetragonal, and tritoxides hexagonal. While this theory is not entirely borne out by the facts, it would probably be more eminently plausible if other portions of our system were more perfect. Thus, though
prototypes, like water and zincic oxide, take the hexagonal instead of the isometric form, this fact leads mineralogists to look upon these minerals as being composed of condensed molecules containing three atoms of each element, and to write their symbols, $\text{H}_2\text{O}_2$ and $\text{Zn}_2\text{O}_3$, rather than reject the theory. This theory does not account for all the examples of polymorphism, nor can they be accounted for without greater knowledge of the crystalline systems. Certain forms in some of the systems, when placed in a particular position, are identical, both in position and angle of the faces, with others in entirely different systems. Nevertheless, none of the efforts to reduce the crystallographic systems below six have been successful. It is, however, established that minerals may be isomorphous with others crystallizing in a different system, when their angles are nearly similar. The variations in the six systems depend upon the relative length of their axes; and when the axial dimensions of two minerals in different systems are nearly the same, they may enter into chemical or physical combination without violence to their individual laws of formation. The likelihood of such replacement is increased by the fact that the crystallographic forms of minerals, though precise in general, are not perfectly uniform in angle. Even the most important and distinctive angular measurements vary decided, and since a certain flexibility thus exists, the entrance of a different though similar mineral may take place without altering the angles beyond their ordinary limits. The extreme variation of axial dimensions which may take place is shown by the common and very well marked mineral calcite, the forms of which include 48 different rhombohedrons and 88 scalenohedrons, besides pyramids and prisms. If the extreme positive rhombohedrons were represented graphically on the same scale, one would be 112 times as long as the other. Yet these extremes are so intimately connected by gradually progressive steps as to forbid any classification of them.—Many theories have been proposed to account for the exact forms assumed by minerals, but two of them will be sufficient to indicate the tendency of speculation. One is chemical. It supposes that the elementary atoms and molecules have definite forms, and that when two elements combine, their molecules take a form which is dependent on the forces that produce the combination. The introduction of a third element may produce a complete rearrangement of the molecules and an entirely new form.

The other theory is based on physical laws. It has been suggested that minerals crystallizing in the isometric system may be composed of spherical molecules, that being the form which any body free to move must take when acted on equally in all directions. Minerals crystallizing in the other systems are made up of ellipsoidal molecules, and the form is tetragonal or rhombic, according as the lateral axes are conjugate axes or conjugate diameters of an ellipsoid. These axes and diameters are equal in all the systems except the triclinic, where they are unequal, and the vertical axis is at right angles to the other two in all but the monoclinic and triclinic systems. The hexagonal form may be produced by an ellipsoid molecule in which three conjugate diameters form the axes on which the faces are laid. These axes are called crystallographic, to distinguish them from the ordinary crystallographic axes, which are entirely distinct. Molecules are supposed to be governed by the laws of polarity, the opposite ends of the conjugate axes or diameters representing the north and south poles. By grouping them according to the known electrical laws, many of the remarkable compound forms can be imitated, and an interesting insight gained into the probable constitution of minerals. Local circumstances will sometimes alter the intensity of attraction between the molecules in favor of some one of the crystallographic axes, and a distorted form will result. A more general modification of molecular relations produces secondary planes. What these local circumstances are is not known, but the character of the mother liquor, or of the solid matrix in which the mineral is formed, is certainly one of them. Laboratory experiments prove this, and in nature we find aragonite assuming different modifications according as it is found in iron mines or in gypsum clays; minerals collected from one locality often present a general likeness, and may differ from the same species found in another region. Since a crystal increases by successive additions to a minute molecular nucleus, any variations in the intensity of the unifying force must produce alternate zones of strong and weak attraction. These pulsations of the formative force are the cause of cleavage, which is due to the lessened tenacity of the mineral along those lines which represent the period of weak action during the pulsation.

III. PHYSICAL CHARACTERISTICS. Fracture, taste, odor, polarization, electrical properties, and transparency are among the least decisive peculiarities of minerals. Streak is a very important character in all classes. Lustre is of great importance in distinguishing the two kinds, metallic and non-metallic minerals. The value of the other physical characters depends upon the kind of mineral under examination. Among those possessing metallic lustre, the hardness, specific gravity, color, and state of aggregation are far more serviceable than with those of non-metallic lustre. The origin of physical properties is unknown, but it is certain that some of them, as transparency, polarization, and refraction, depend upon the relations of the molecules toward light; lustre, color, and streak may have a similar origin, varied by the operation of the forces which formed the mineral. To these forces, tenacity, ductility, and state of aggregation may also probably be ascribed. Some of the above mentioned charac-
teters, and also hardness and specific gravity, may be due partly or entirely to the state of chemical combination. It has been shown that the superior hardness and specific gravity of the epidote group of minerals, as compared with the scapolite group, may be explained by supposing that the molecule of the former is more condensed than that of the latter.—

Classification of Minerals. The explanations above given embody the leading principles upon which the numerous minerals found in nature are distinguished from each other and arranged in related groups. The unit in mineralogy is the species. A mineral species must have a definite composition and individual characteristics of form, sufficient to establish its difference from all others. The mode of occurrence may be gaseous, fluid, or solid; the nitrogen and oxygen of the atmosphere, water, and mercury are all native minerals, as well as the solid substances. But definiteness of composition is a necessary characteristic, and marks the difference between minerals and rocks. While the latter are composed of mineral substances, the indefiniteness of their constitution prevents their classification and description by the accurate methods known in mineralogy. Even in the latter science a certain latitude in composition is necessarily allowed, as minerals are seldom perfectly pure. Elements foreign to those which properly compose the mineral are nearly always present, and when their amount is large in proportion to the whole, it may be a question whether a new species should be made. The tendency of the best authorities is to restrict the number of species as much as possible, and to describe the modifications, where the usual characteristics of the mineral are not much altered, as varieties. Thus under pyroxene Prof. Dana describes 21 varieties, and under amphibole 20. Tourmaline has already been cited as a case of extreme variation in chemical composition, and calcite in crystalline form, the variation in both cases being in remarkably well characteristic species. In the fifth edition of Dana's "Mineralogy" (1868), 883 species are described, and the number of varieties is probably two or three times as great. The classification of these species is based upon chemical composition; compounds of one kind, as silicates or sulphides, being placed together and subdivided into groups having the same general symbol, or the same crystalline form, or some common physical character. The arrangement according to composition will be understood by referring to the table of elements given above. Six general divisions are made: 1. Native elements, including any element in the pure state, and any compound of two elements in the same series and group. There are 20 elements known, forming 25 mineral species. Gold, silver, platinum, iridium, palladium, mercury, copper, lead, arsenic, antimony, bismuth, telurium, sulphur, selenium, carbon, nitrogen, and oxygen are certainly found native; while iron, zinc, and tin, though reported, are somewhat doubtful, if meteoric iron is excluded as not having been subjected to terrestrial conditions. When elements from two or more groups are united in a mineral, we are brought to the study of compounds, which forms all the remaining part of mineralogy, including five divisions. 2. All compounds in which the negative element is taken from the arsenic or sulphur group (series II. in the table). This division therefore includes phosphates, arsenides, antimonides, bismuthides, sulphides, selenides, tellurides, and double compounds, as sulphoantimonides, sulpho-bismuthides, &c.; in all, 110 species. 3. Compounds in which the negative element is taken from group A, series III., and therefore this division comprises all chlorides, bromides, and iodides, numbering 23 species. 4. Compounds containing the negative element of group B, series III., or fluorides, 13 in number. 5. Oxygen compounds, the negative element being taken from group C, series III. This division exceeds all others in the number of its species (587) and in the abundance of its minerals, which form probably more than nine tenths of the globe. 6. Those compounds of hydrogen and carbon which are called "organic," of which 73 species are recognized. In addition to the above, more than 100 new species have been reported since 1868, and though some of these may not be sustained, the interest taken in mineralogy as a speculative science is rapidly extending our knowledge of minerals and the discovery of new species. A general classification of species having been made according to chemical composition, as above explained, groups are formed, each of which contains minerals of one type. A mineral type includes species which closely resemble each other in crystalline form, and have a related elementary composition. Thus eight similar compounds of protioxides and dextrooxides are found to crystallize in the isometric system, and are all of the "spinel type." Crystallized minerals containing ferric anhydride assume either inclined or hemihedral forms, and therefore constitute a well marked type. Amorphous minerals are necessarily classed with those crystalline species which they resemble in composition, as their lack of definite form is looked upon not as a characteristic, but as the lack of one. This mode of ranking them does no violence to the theory held by some that they are formed from matter in the colloidal state. No uniform system of comparison has yet been discovered which will suit the requirements of all classes of minerals. Each element appears to have a definite form, which it tends to assume under all circumstances; and if the strength of this tendency varies with each one, the form of any given species will either be that of some dominant element, or a compound one resulting from the interaction of all the substances contained in it. But nothing is known of such a scale of crystallographic forces except that, in the some-
what casual juxtapositions brought about by the present system of arrangement, we find different compounds, such as sulphates and carbonates, crystallized in different forms; while a species which is a compound of both these, a sulphato-carbonate, has the general form of the sulphates. From this fact it is concluded that sulphur has a more energetic formative power than carbon. An excellent and simple example of the principles on which mineral types and groups are arranged will be found in Dana's "Mineralogy," fifth edition, p. 94, under the head of "Sulphides."—Nomenclature. Mineralogists have chosen the termination ite to characterize the names of their species. Ite or itas was used by the Greeks and Romans for this purpose, and it was appended to some word signifying a quality, locality, or some other fact relating to the mineral. Itronites, for instance, referred to the red color of the powder, and syenites took its name from Syene in Egypt. Werner, in the last century, introduced the custom of naming minerals after persons, and, though much opposed for years, especially by French mineralogists, this is now the common usage. Its popularity does not spring so much from the desire to do honor to discoverers and distinguished men, as from the liability to error when an attempt is made to name a mineral from some supposed quality while the information about it is still imperfect. Many other terminations are in use, as ine, ane, ene, ane, age, one, ote, &c.; but these have come down to us from former years. At present the rule is to use the termination ite, or if another is employed the latter must be applied to all minerals of the same class. A great advance in uniformity has been made by Dana, who undertook a thorough collation of the literature of the science, and applied the law of priority wherever it could be done without injury, thus restoring many old names. While ite is used for minerals, gte is used for rock masses, which, to deserve the application of the word, should consist principally or entirely of the compact mineral. Thus dolerite and pyroxenite are massive deposits of the minerals dolerite and pyroxene.—Mineralogy is the name given to the study of the laws which govern the formation of minerals. While the chemist constantly endeavors to work with pure materials and to have but few elements present in the artificial production of mineral compounds, nature has undoubtedly formed many or all of the mineral species from sources in which a great number of elements were mixed. The circumstances under which these elements were brought together, their proportion, and the influences to which they were individually or collectively subjected afterward, must have varied within very wide limits; and the fact that definite and unvarying species have been produced from heterogeneous compounds is proof of the operation of fixed and probably simple laws. On the other hand, the slight differences which are noticeable in the characteristic marks of a great many species are probably the traces of the different conditions under which the individuals of the species were formed. The development of these laws, and of the forces which have modified them, forms the speculative part of mineralogical science, and makes the science itself an important factor both in the history of the earth and in the development of chemical knowledge. The present state of this knowledge will not permit a trustworthy statement of mineralogical facts within the limits of this article. It is sufficient to point out some of the modes in which compounds may be formed. These are: 1, union of two gaseous elements; 2, union of one gaseous and one fluid or solid element; 3, union of two fluids; 4, union of one fluid and one solid; 5, combinations at a high temperature (igneous fluidity forming a matrix from which species separate on cooling); 6, combinations at a low temperature.—Artificial Minerals. By imitating these and other processes, many of the characteristic species may be reproduced, and the combinations always show themselves to be governed by the same laws that are discernible in the formation of true minerals. These artificial minerals mostly result from three sources: the study of chemical laws by experimental processes, the desire to produce gems by artificial means, and the casual formation of definite mineral compounds in metallurgical work. Of the salts which result from chemical reactions, a great number have been found in nature. Of minerals used as gems, the ruby, aquamarine, garnet, topaz, spinel, chrysoberyl, apatite, and others have been produced, but not of a size large enough to make them useful as ornaments or their manufacture profitable. Metallurgical processes, where high temperatures and the action of gaseous substances are long continued, and where compounds of all degrees of fusibility are melted and chemically combined, are a fruitful source of artificial and very perfect minerals. A few furnace products have never been found in nature. While artificial minerals are apt to be less perfectly crystallized than the native specimens, they are also apt to be of simpler forms, and have sometimes served to determine the primitive angle when it could not be decided by natural specimens.—Historical. While the ancients were acquainted with a great number of minerals, and observed the existence of crystals and the importance of physical characters, their complete ignorance of all our modes of investigation prevented their obtaining any real knowledge of the distinctive species. Stones of the most diverse composition, some minerals and some rocks, were grouped under one name, and it is frequently impossible to recognize from their description the minerals they knew. Theophrastus (315 B. C.) was the earliest writer on the subject, though other authors frequently referred to minerals as rem-
edies, usually of the miraculous kind. Passing to the Christian era, we find Pliny writing on this subject in the 1st century, and Dioscorides in the same or the following; after which there is a blank until the 11th century, when Avicenna divided minerals into four classes, stones, salts, sulphurous or inflammable bodies, and earths. The "stones" were chiefly silicates, and rude as this classification is, it was not until long after chemical science had made its mark that anything very much superior was advanced, the principal improvement made in more than six centuries being the substitution of metals for "stones." Agriola (1485–50) wrote several works, studied the external characters of minerals, and based his arrangement upon those which are apparent to the senses. The alchemical studies of the succeeding centuries bore some fruit, both in the discovery of new species and in the addition of heat and fusion as modes of investigation. Passing over Linnaeus (1735) and Wallerius (1747), who was the first to write a systematic descriptive work on this subject, we come to Cronstedt of Sweden, who in 1758 first pointed out the distinction between rocks and minerals which now enters into the fundamental definition of the latter.

He based his system upon chemical properties. Romé de Lisle, in 1772–85, made the first systematic effort to apply the principles of crystallography to the science, though Nicholaes Steno had in the preceding century pointed out the fundamental fact that, with all their variations of form, the faces of crystals preserved the same angular relations; and later Gmelinmini discovered that cleavage gave constant forms. Werner of Freiberg published in 1774 a work on the "External Characters of Minerals," in which he gave a much needed precision to the descriptive part of mineralogy, and retained the "natural affinity," or chemical affinity, of the generation, as the basis of classification; though the mode of carrying out the idea recalls Avicenna's work, seven centuries before. Werner also made four classes, earths, salts, inflammables, and metals, the first named being further divided into silicious, argillaceous, calcareous, and talceous; but the silicious division was made to include nearly all the hard minerals, without regard to composition.

It was under this form that mineralogy was introduced to English students by Kirwan in 1784. The idea now began to receive constant and important additions, the three modes of determination which still remain criteria (crystalline form, chemical composition, and physical characters) being each in turn elevated to a position of dominant importance. In 1783 De Lisle published a second edition, in which crystallography received increased attention; and in 1801 Hûty's Traité de minéralogie appeared, in which crystallography was made the principal agent in the determination of mineral species. He rediscovered the importance of cleavage, and afforded a mathematical explanation of the phenomenon, referred the numerous secondary forms to a fundamental molecule of invariable shape, and reduced all crystal forms to six systems, based upon the following forms: 1, the regular octahedron; 2, the rhombohedron; 3, octahedron with a square base; 4, the octahedron with a rectangular base; 5, the prism with a symmetrical oblique base; and 6, the prism with an unsymmetrical oblique base.

By reference to the article Crystallography it will be seen that, though the details of his system have been changed, the axial differences recognized by him remain. In his system chemical composition and physical characters were entirely subordinate to crystallographic habits. He made four classes: 1, free acids; 2, substances which are metallic but do not present a metallic appearance, in which were included the eight genera, lime, barytes, strontites, magnesia, alumina, potash, soda, and ammonia, together with the silicates; 3, metallic substances; 4, unmetallic combustible substances.

In 1804 Mohs of Vienna published a description of a collection of minerals, in which the external characteristics alone were used to describe them. In 1820 he expanded his ideas into a "Natural History" system, the object of which was to group together all minerals which presented similar characters in regard to taste, lustre, gravity, streak, hardness, &c. No tests were used which destroyed the mineral, such as acids and fusion. Each group was gradually reduced by a process of comparison and exclusion to its individual members. This method was borrowed from other fields of science, and its nomenclature repeated the classes, orders, and genera of zoology and botany. The system, though it has proved to be entirely unfitted to this science, did much good by requiring greater precision in description, bringing out many true relationships between substances, and discarding unimportant distinctions which were flooding the science with false species. It is still used, with modifications, in mineralogical keys which are constructed for the use of young students, and persons little versed in the study. Mohs's classification included three classes: class 1 contained four orders, gas, water, acid, and salt, and included bodies which have taste, give no bituminous odor, and have a gravity below 1.8; class 2, bodies which have no taste, but are of specific gravity above 1.8; class 3, fluid bodies with bituminous odor, and tasteless bodies of specific gravity below 1.8. This system was received with great favor, and not only held sway in Germany for 40 years, but extended into England and America. Two of the modes of determining minerals, crystalline form and physical characters, had now received the attention of able advocates, and were in rapid process of development by mineralogists throughout the world. The third, that which stands at the head in the present system, is chemical composition, which received from
Berzelius some time before 1816 (French edition, 1819) its first decisive impetus. That chemist looked upon mineralogy as properly a mere branch of his own favorite science. He explained mineral as he explained other compounds on the dualistic theory, according to which they were made up of an electro-positive and an electro-negative element or radical. His classification included two great groups, the first composed of native metals and binaries, not containing oxygen; and the second of electro-positive and electro-negative oxides, hydrates, silicates, alumina-silicates, tungstes, borates, carbonates, &c.; each acid, or each electro-negative element, having its own division as now. He introduced into the science the exact methods of chemistry, and urged the necessity of constant analysis, so that the existing mode of mineralogical study is known as the Berzelian, improved by the addition of crystallography and the special study of external marks.—While the science was thus receiving constant accessions in Germany and Sweden, the French mineralogists were also working out various schemes of classification. Unable to produce a harmonious arrangement on any simple plan, they adopted a mixed system. Brongniart, in his Traité élémentaire (1807) and Tableau des espèces minérales (1853), classified the earthy minerals according to the negative element, and the metallic ones according to the positive element. He had two grand divisions, the inorganic and organic. In the first were included 20 "mineralizers," such as oxygen, hydrogen, and sulphur; the second class, métaux autopsides, contains true metals and their compounds; while the third class, métaux hétéropsides, contains other bases and forms two orders, one of compounds without, and one of those with oxygen. Beudant, in his Traité de minéralogie (1824), endeavored to restrict the classification of minerals to their chemical reactions. He formed three grand genera, based upon the characteristic negative element. Gazoloytes contained a negative element capable of forming stable gaseous compounds with oxygen, hydrogen, or fluoric acid, and included carbon, silicon, chlorine, &c. Leucoloytes contained a negative element which does not form such stable gaseous compounds, but gives colorless solutions with acids. Chrocoloytes, on the other hand, give colored solutions with acids. Though this arrangement supplanted that of Haly, the groupings of minerals formed under it were of the most heterogeneous character. Dufrenoy in 1844 published the first edition of a treatise in which a mixed system was again presented. He recognized natural groups in some of which the bases bore the important part, and in others the acids. In these mixed systems the bases are the real ground of classification, but the importance and number of the silicates, and the fact that the base plays a secondary part in most of them, compel an exception to be made in their favor in any scheme where the bases are made the characteristic elements. The French school has always been distinguished for eminence in crystallographic and physical researches, the latest development of which is to be seen in DescloiZeaux's admirable investigations into the optical properties of minerals, by which the recognition of many obscure species has been greatly aided. The mixed classification of the French, however, has been rejected, partly for its incongruity and partly because the new chemical methods have been altogether in favor of the Berzelian mode.—In 1840 Gustav Rose of Berlin published a work on crystallography, in which the six crystalline systems formed the general divisions, in each of which the minerals were arranged in genera and species, according to their chemical composition. In 1852 he published his Krystallchemisches Mineralystem, in which the chemical composition is used both to determine the general arrangement and to fix the individual species, which are grouped into genera by their crystallographic characters. His method of arrangement was: 1 , simple bodies; 2, compounds of sulphur, selenium, tellurium, arsenic, and antimony; 3, compounds of chlorine, fluorine, iodine, and bromine, the oxygen compounds. Rammelsberg, in several works, and especially in his Handbuch der Mineralchemie, has paid great attention to the constitution of minerals, their relationships, the laws regulating their formation, and similar questions. K. G. Bischof, in his Lehrbuch der chemischen und physikalischen Geologie, entered into the genesis of minerals, and, though his views have been frequently rebutted, he exerted a marked influence upon the progress of the science. Germany continues to be one of the most active fields for the advancement of this science. Tschermach, Ly, and others issue periodical reviews of progress, mineralogical magazines are published, and a great number of works on the science in all its branches are constantly issued. The German school now probably includes a greater number of distinguished names than any other, though the science is rapidly advancing in all countries.—In the United States mineralogy had been but little cultivated before the beginning of the present century. A few collections of minerals had been brought from Europe, but the treatises of Kirwan and Jameson were almost the only works at that time. They were consulted with reference to them, and very few were acquainted with these. In 1816 Prof. Parker Cleveland of Bowdoin college published "An Elementary Treatise on Mineralogy and Geology," which was well received both in America and in Europe as a work of scientific importance, and particularly useful for the information it afforded respecting American minerals. The author, following the general plan of Brongniart at that time, sought to unite with the precise descriptive language of the system of Werner the chemical classification of the French mineralogists. His work was
for many years highly popular, and indeed almost the only one in use by American mineralogists. A second edition appeared in 1822. Ten years afterward Prof. Charles U. Shepard of New Haven published the first part of his "Treatise on Mineralogy," and in 1855 the second part. He adopted the arrangement of Mohs with little variation, making the natural history for external characters as far as possible the means of determining the species. He however appended a table in which the minerals were also arranged according to their chemical affinities. Francis Alger of Boston republished the then recent "Treatise on Mineralogy" prepared by Robert Allan from Phillips's "Mineralogy," enlarging it by numerous notices of American minerals and of recent discoveries. Like the last named work, it was particularly interesting for presenting many new facts in the development of the mineralogy of the United States. Prof. James D. Dana of New Haven commenced in 1837 the publication of his treatises upon mineralogy by the issue of the first edition of "A System of Mineralogy, including an extended Treatise upon Crystallography." Five editions of this work have been published. In those of 1837 and 1844 the natural history system of Mohs was extended and solidified, but in the third edition this was abandoned, and the author presented his work with a classification that claimed no inherent virtue but convenience. He however suggested a combination of the chemical and crystallographic methods, which in 1854 was embodied with alterations in a fourth edition. During the 17 years covered by this work the views of the English school of chemists were steadily gaining ground, and when the fifth edition appeared in 1868 the "new chemistry" with its rational symbols and its new tenets had been established, and was used by the side of the old method in this work. The system of arrangement in the foregoing part of this article. No attempt is made to afford students a tabular arrangement by which the name of given specimens can be ascertained. The book bears to minerals a relation similar to that which a dictionary bears to words; it gives accurate definitions of them on a systematic plan. Great care has been taken with these definitions, and in fact Prof. Dana's method does not commence with the system, but with the species. When all the facts of composition, crystal form, and physical characters of a species are known, it can readily be placed with those of a similar kind, and minerals which resemble each other in these things necessarily form a group. Partial differences give rise to sub-groups, and resemblances between entire groups cause the formation of divisions. The system is therefore strictly rational. In other respects Dana's fifth edition is a great advance upon any previous publication in this branch of science. He has adopted fixed rules for nomenclature and orthography, collated almost every work for synonyms, which are arranged in chronological order, and performed much similar work in a way that seems to leave nothing to be desired. MINERAL POINT, a city and the capital of Iowa co., Wisconsin, on a branch of the Pecatonica river, 47 m. W. S. W. of Madison, and at the terminus of the Mineral Point railroad (38 m. long), connecting it with the Illinois Central railroad at Warren, Ill.; pop. in 1870, 3,275. It is in the midst of a rich mineral region, yielding lead, copper, and zinc, and contains several hotels, numerous stores, foundries, smelting works for lead and zinc, and breweries. There are eight public schools, including a high school, three private schools, two weekly newspapers, and five churches.

MINERAL SPRINGS, those which are impregnated with minerals to such a degree as to possess medicinal properties. They differ from ordinary springs in the larger volume of gas, especially carbonic acid gas, the mineral ingredients held in solution in their waters, and the peculiar smell, taste, and sometimes color imparted by the solution; many of them also by a higher temperature, called thermal springs (75° to 212° F.). Some issue from the earth like fountains, foaming and steaming; others with a continuous or intermittent noise, gurgling and hissing. Like ordinary springs, they are found at every altitude and in all climates. Some break at boiling heat through a crust of ice and snow, and some issue with almost ice-coldness from among luxuriant vegetation. Many sulphur springs destroy all vegetation around them; others (calcareous) cover organic structures with incrustations. The waters of mineral springs are used both for drinking and bathing; their vapors for baths; and their spray, with the evolved gases, for inhaling. The ancients ascribed supernatural properties to mineral springs, and their priests, especially those of Asculapius, placed their sanctuaries near them, and as at the alkaline springs of Nympha and the gas springs of Dodona. Such places were provided not only with baths, hospitals, and medical schools, but also with theatres and other resorts for amusement, and were designed both for worship and for the cure of the sick. According to Strabo, the springs of Hierapolis imparted a red color to the roots of trees and shrubs, and the juices of the latter mixed with the water produced a purple dye. Philostratus says that the Greek soldiers wounded in the battle on the Caunes were healed by the waters of Agamemnon's spring near Smyrna. The pythons was thought to be inspired by bathing in the Castalian spring and inhaling the vapors of the steaming cave at Delphi. Josephus relates that Herod sought relief from his terrible disease in the thermal springs of Callirrhoe. The springs of Tiberias, which have a temperature of from 86° to 130° F., were used by the Romans, and are still frequented by patients from all parts of Asia Minor. The most celebrated bathing place of the Roman empire was the hot sulphur springs.
MINERAL SPRINGS

(190° F.) of Baiae on the gulf of Naples. Ischia, once covered with the villas and palaces of the Romans, still maintains the reputation of its thermal waters and vapor baths. The Romans discovered many of the most important thermal springs of Europe, and used them as army stations; among them are Baden-Baden, Wiesbaden, Bath, Aix-la-Chapelle, and Spa. Carlsbad was named after Charles IV., who is said to have discovered the Sprudel in 1847 or 1858, while hunting.—Many theories, both natural and supernatural, have been propounded by philosophers in all ages to account for the origin and properties of mineral springs; but modern analytical chemistry has dissolved the demons of the ancient and the wild spirits of Paracelsus (De Agis Mineralibus, 1562) into our familiar carbonic acid gas. Van Helmont's discovery of the alkalies and fixed air in the early part of the 17th century was the first step in this direction. Arago proved that the temperature of the springs corresponds with the depth from which they rise. Bergman, Berzelius, Bischof, and Struve showed that their composition depends on the amount of carbonic acid and other gases which are dissolved in them, consequent on their volcanic origin and on the nature of the rocks which they permeate; and Faraday, Liebig, and other chemists established the principles of a thorough analysis. During the past 50 years many mineral springs have been discovered, and all of note have repeatedly been analyzed. These analyses vary in their results with the changes to which the various springs are from time to time subject. The waters of the Kissingen Rakoczy spring lost 22 per cent. of mineral ingredients from 1830 to 1855, and underwent a change also in their relative proportions. At the time of the great earthquake of Lisbon (1755) the Carlsbad springs ceased flowing for three days.—Of the mineral springs of Europe, France contains about 900; Germany, Austria, and Switzerland, about 2,500; England, over 100; Spain, 1,200; Portugal, 200; and Italy, 800, two thirds of which are in Tuscany. The most important constituent of the waters of all spas, as mineral springs are frequently called, is carbonic acid gas, with which the muriated and muriated-alkaline springs are impregnated most, the saline, alkaline, and bitter waters least. According to Liebig, Kissingen Rakoczy contains in 16 oz. 41-77 cubic inches of carbonic acid, Carls-bad 14, and Kissingen bitter water only 5-9.

Nitrogen gas occurs especially in hot sulphur springs, with carbureted hydrogen, oxygen, and sulphuretted hydrogen as lesser gaseous ingredients. Mineral springs are classified as follows, according to the salts from which they derive their specific importance. 1. Chalybeate or Ferruginous Springs. The distinguishing characteristic of these is the presence of iron dissolved as a bicarbonate or in the inferior ones as a sulphate. Their other ingredients are bichromates of manganese, soda, lime, and magnesia, chloride of sodium, sulphate of soda and of potash, &c. Their water, which has an inky taste, is most effective as a remedy for anemia and chlorosis, by augmenting the number of blood globules and their hematine, and by diminishing the phosphoric acid in the urine. The strongest chalybeate spring, Schwabach in Germany, contains much carbonic acid gas, and, with the exception of iron, only a small amount of saline ingredients. Other chalybeates of note are Pyrmont, Altwasser, Reinzer, Brückenau, Steben, Drifur, Wildungen, Cudown, and Franzenbad, in Germany and Cisleithan Austria; Buzáis, in Hungary; St. Maurice, in the Engadine, Switzerland; Spa, in Belgium; Passy, Forges, Bussang, Plombières, Bagnères-d'Adour, and Dinant, in France; Cheltenham, Tunbridge, Scarborough, and Wells, in England; Bibiana, Catarina, Staro, and La Croix, in Italy; and Loka, in Sweden. In the United States the most noted chalybeate springs are: Schooley's Mountain springs, Morris co., N. J.; Fry's soda spring, near Mt. Shasta, Cal.; Stafford springs, Tolland co., Conn.; Greencastle springs, Putnam co., Ind.; Cataoo springs, Cataooa, Ga.; Schuyler county springs, Ill.; Owasso springs, Shiawassee co., Mich.; Cooper's well, Hills co., Miss.; Beersheba springs, Grundy co., Tenn.; Rawley springs, Rockingham co., Va.; and Bayley springs (alkaline-chalybeate), Lauderdale co., Ala. Dr. Walton includes also in this class the so-called alum waters of Virginia, viz.: the Rockbridge, Pulaski, and Bath alum springs; Stirling springs in Augusta co.; Church Hill alum springs, near Richmond; Bedford alum springs, near New London; and Variety springs in Augusta co.; also in the Oak Orchard acid springs, Genesee co., N. Y., and the Tascarora sour springs, Wentworth, co., Canada. He also names, as calcic-chalybeate waters, the sweet chalybeate springs, Alleghany co., Va.; Montvale spring, Blount co., Tenn.; and Hot Red springs (103°F.), Utah. Many iron waters are strongly impregnated with saline or alkaline chalybeates, and will be mentioned in speaking of saline and alkaline springs. 2. Muriated Springs. In these there is an excess of chloride of sodium and of carbonic acid gas, and they are mainly diuretic, or, according to Hanbury Smith, tonic and alterative, and effective in species of abdominal diseases, chronic rheumatism, and cutaneous complaints. According to Liebig, 16 oz. of Kissingen Rakoczy, the representative water of this class, contains chloride of sodium 44-7 grains, chloride of potassium 2-2, chloride of lithium 0-15, magnesium 2-23, bromide of sodium 0-064, nitrate of soda 0-07, sulphate of magnesia 4-5, sulphate of lime 2-99, carbonate of magnesia 0-15, carbonate of lime 8-1, protoxide of iron 0-24, phosphate of lime 0-046, silicea 0-09, ammonia 0-007, and traces of iodide of sodium, borate of soda, &c. Springs allied to it are Rodna in Transylvania, Lomberg (muriated-chalybeate), the tepid waters of
There were also traces of fluoride of calcium, bichromate of soda, and organic matter. Saratoga waters possess tonic and cathartic properties, and are therefore especially adapted to cases of dyspepsia, jaundice, calculus, and engorgement of the liver. (See SARATOGA SPRINGS.) Allied springs are: Congress spring, Santa Clara co., Cal.; Rockbridge baths, Rockbridge co., Va. (74°F); Capon springs and bath, Hampshire co., W. Va.; Artesian well, St. Louis, Mo. (2,199 ft deep); Spring Lake well and Fruit Port well, Ottawa co., Mich., which much resemble the celebrated waters of Creuznach, Prussia; and St. Catharine's wells, Ontario, Canada, also similar to Creuznach, but stronger. Plantagenet or Caratca and Caleidonia springs, in the same province of Canada, are fine types of iodo-bromated saline waters. 3. Sulphur Springs. These are impregnated with nitrogen and sulphuretted hydrogen gas. Cold sulphur springs are indicated as effective in catarrhal affections of the lungs and throat, and in hemorrhoids. Such are Weilbach, Neundorf, Eilsen, Langenbruecken, in Germany; Stachelberg in Glarus, Switzerland; Montmorency, La Roche, and St. Amand, in France; Harrowgate, Thanet township, and Butterby, in England; and many in Italy. Thermal sulphur springs are recommended in rheumatism and gout. Among these are Aix-la-Chapelle and Bartscheid (Kochbrunn, 166°F), in Prussia; Baden, near Vienna; Barèges, Bagneres-de-Luchon, Languedoc, Arles, St. Sauveur, Ax, Digne, and Aix-les-Bains, in France; Abano, Fossombrone, Volterra, Viterbo, Pozzuoli, Castellamare, etc., in Italy; Baden and Schonzach, in Switzerland; Melisenda and Treneseny-Toepitz, in Hungary; the Caldas of Rainha and Gerez in Portugal, and of Orense and Lugo, in Spain; and Ramlosa, in Sweden. The principal cold sulphur springs in the United States are: Alpena well, Mich.; Cold White Sulphur springs, Rockbridge co., Montgomery White Sulphur springs and the Seven Fountains or Burner's springs, Shenandoah co., Red Sulphur springs, Monroe co., and Greenbrier White Sulphur springs and Greenbrier Blue Sulphur springs, Greenbrier co., W. Va.; Sharon springs, Schoharie co., Richfield and Cherry Valley springs, Otsego co., Arvon springs, Livingston co., and Columbia springs, Columbia co., N. Y.; Bedford springs, Trimble co., Esclapias springs, Lewis co., Fox springs, Fleming co., and White Sulphur and Tar springs, Breckenridge co., Ky.; De Soto springs, La.; Green Cove springs, Clay co., Fla.; Red Sulphur springs, Walker co., Ga., and French Lick springs, Orange co., Ind. The Sandwich springs, Ontario, Canada, are also of this class. Of saline sulphur waters, applicable to the treatment of drurtons or herpetic diseases of the skin, the most noted are: West Baden springs, Orange co., Indian springs, Martin co., Lodi Artesian well, Wabash co., and Lafayette well (55°F), Tippecanoe co., Ind.; the upper and lower Blue Lick springs, Nicholas co., Big Bone springs, Boone co., Paroquet springs, Ballitúa co., and Olympian springs, Bath co., Ky.; Blount springs, Ala.; Massena springs, St. Lawrence co., N. Y., which resemble those of Eilsen, Germany; and Salt Sulphur springs, Monroe co., W. Va. Of calcic sulphur waters, prescribed in cases which otherwise would require sulphur waters, but which are complicated by disease of the bladder, the principal springs are: Chittenango springs, Madison co., and Clifton springs, Ontario co., N. Y.; and Yellow Sulphur springs, Montgomery co., Va. The principal thermal sulphur springs in the United States are: Caledonia hot springs, Napa co. (about 60 springs, varying from lukewarm to boiling hot), the Geyser, Sonoma co. (about 100 springs, varying from 97°F to 195°F), Paso Robles hot springs, San Luis Obispo co. (112°F to 125°F), and allied to the waters of Aix-la-Chapelle), Santa Barbara hot sulphur springs (60°F to 130°F), and Agua Caliente or Dr. Warner's ranch spring (136°F to 142°F), San Diego co., Cal.; Louisville
artesian well (76°), Ky.; Middle Park hot sulphur springs (111° to 116°), Summit co., Col.; Salt Lake hot springs (110° to 128°), Salt Lake City, Utah; Warm springs (90°), Merri- wether co., Ga.; Warm springs (96° to 98°), Bath co., Va.; and the Geyser or Warm Sulphur springs (90° to 104°), about 20 m. from Sitka, Alaska. 4. **Alkaline Springs.** The waters of alkaline springs increase, by their excess of carbonate of soda, the alkalinity and fluidity of the blood. Their action is diuretic, and they are efficacious in all affections of the kidneys, in catarrhs, in affections of the stomach, bladder, and abdomen, and in indigestion, jaundice, gout, and diabetes. According to Bauer, 16 oz. of the water of the Grande Grille (107°) of Vichy contains carbonate of soda 29-19 grains, carbonate of lime 1-92, ammonia 0-056, strontia 0-0175, magnesia 0-02, sulphate of potash 1-567, soda 0-9, phosphate of soda 0-082, and chlorides of soda 4-445. The Josephquelle of Bilin, Bohemia, contains about 23 grains of carbonate of soda in the same quantity of water. Other noted alkaline springs are Buda, in Hungary; Valis, Aix, Chandes-Aignes, Néris-les-Bains, and Luxeuil, in France; Gieshütel near Carlsbad, Fachingen, Gellman, and the muriated alkaline or acidic springs of Selters, Ems, and Salzbrunn, in Germany; Bristol, Buxton, and Dunblane, in Great Britain; Carlsbad, in France; Asciano, A劲na, and No- cera, in Italy. The principal constituents of the famous Selters and allied waters, used in acute catarrh and pulmonary affections, are chloride of sodium, carbonate of soda, and carbonic acid gas. The principal alkaline springs of the United States are: Bladon springs, Chocow co., Ala.; California Seltzer springs, Mendocino co.; Perry springs, Pike co., and Versailles springs, Brown co., Ill.; St. Louis springs, Gratiot co., Mich.; Sheldon springs (including the Mississip spring), Franklin co., and Well- don springs, St. Albans, Vt.; and the newly discovered waters of the Charters spring (143°, 145°), Wasco co., Oregon. 5. **Alkaline Saline Springs.** The waters of these springs are most efficient in diseases of the liver and abdominal plethora, obesity, gout, and calculi. Their representatives are the thermal springs (117° to 165°) of Carlsbad in Bohemia, nine of which are in use. The famous Sprudel, which used to spout 18 to 20 times a minute, rising from 4 to 8 ft., contains, according to Berzelius and Bauer, in 16 oz., sulphate of soda 19-28 grains, chloride of soda 7-97, carbonate of soda 10-13, carbonate of lime 2-37, carbonate of magnesia 1-969, carbonate of lithia 0-02, and fluoride of calcium 0-024. To this class belong the curative cold waters of Marienbad in Bohemia, Robitsch in Styria, and the thermal Ber- trich in Rhineland; Dax, Bagnères-d'Adour, and Ussat, in France; and Bath and Matlock, in England. In the United States the chief springs of this class are: Lansing well, Ingham co., Mich.; Ballston Spa, Saratoga co., and the Albany artesian well (500 ft. deep), N. Y.; Mil- hoit's soda springs, Clackamas co., Oregon; and the thermal, Idaho hot springs (85° to 115°), Clear Creek co., Col., and Charleston artesian well (87°, 1,250 ft. deep), Charleston, S. C. 6. **Purgative or Bitter Waters.** These waters de- rive their latter name from the taste of their chief ingredients, sulphate of soda (Glauber's salts) and sulphate of magnesia (Epsom salts). When taken in moderate doses they act as gentle purgatives and strong diuretics, and are useful therefore in all cases requiring active saline purgation. They are especially applicable to persons of robust constitution, with a tendency to abdominal plethora. The Kissingen bitter water contains, in 16 oz., sulphate of soda 46-81 grains, sulphate of magnesia 38-55, chloride of sodium 61-10, chloride of magnesia 30-65, chloride of ammonium 0-02, and chloride of lithium 0-00. Friedrichshall in Saxe-Meiningen, Püllna, Seidschütz, and Seid- litz in Bohemia, Epsom in England, Campagne- sur-Aude in France, and Ivánda in Hungary, are famous bitter waters. Of springs of this class in the United States, Crab Orchard springs, Lincoln co., Ky., produce the Crab Orchard salts, which are made by boiling down the water. Estill or Irvine springs, Estill co., Ky., are strongly impregnated with sulphate of magnesia. Harrodsburg springs, Mercer co., Ky., are modified in their laxative effect by equal amounts of sulphate of lime and of chloride of iron. Bedford springs, Bedford co., Pa., are purgative-chalybeate. Allied waters are: Beer springs, Oregon; Midland well, Midland co., Mich.; and Elgin spring, Addison co., Vt. 7. **Calcic Springs.** These are rich in carbonate of lime (limestone), or sulphate of lime (gypsum), mixed with iron, and with saline, alka- line, and other ingredients. Bathing in these waters cures exanthema, indigestion, and rheu- matic and gouty affections. Drinking them, especially those rich in carbonate of lime and carbonic acid, such as the Wildungen water, provides them with gravel and calculus, and in gastrical dys- pepsia. The following calcic thermal waters are regarded as of great therapeutical value: Lenk (158°), canton of Valais, and Weissenberg (trepid), in Bern, Switzerland; Lucca and Montione, in Italy; and in the United States, San Bernardino hot springs (100° to 172°), Cal.; Agua Caliente (130°), Mesilla co., N. M.; Sweet springs (74°), Monroe co., W. Va.; Berkeley springs (74°), in Bath, Morgan co., W. Va.; Warn springs (97° to 102°), Madison co., N. O.; and Bethesda springs (66°), Wankesha, Wis. (calcic-alkaline, efficient in urinary diseases). The principal cold calcic springs are: Wildungen, Waldeck, Germany; Contrex- éville, Vosges, France; in the United States, Butterworth springs, Kent co., Leslie well, Ingham co., Eaton Rapids wells, Eaton co., and Hubbardston well, Ionia co., Mich.; Yellow springs, Greene co., Ohio; and Gettysburg springs, Adams co., Pa. 8. **Indifferent Thermal Springs.** This class contains but small
MINERAL SPRINGS

amounts of salts and alkalines, the beneficial effect of bathing in their waters resulting mainly from their increased temperature (75° to 160°). These baths are efficacious especially in paralysis, articular and muscular rheumatism, old wounds, enervation, and decrepitude. The most noted are: Gastein, in Salzburg, Austria (eight springs, from 95° to 160°); Wildbad, in Württemberg; Püfners and Ragatz, in Switzerland; Tepitz and Johannesbad, in Bohemia; Warmbrunn and Landeck, in Prussian Silesia; Schlangenbad, in Hesse-Nassau, applicable especially to hysteria and skin diseases; Dombières, Voges, France, efficacious in gastralgia, rheumatism, and dartsous diseases of the skin; Bains, in Alsace; Alhama de Granada, in Spain; and San Martino, in Lombardy.

In the United States the most noted of this class are: Hot springs (57 springs, from 95° to 150°), Hot Springs co., Ark., which resemble those of Gastein and Pfiffers; Healing springs, Bath co., Va., applicable to all ulcerated conditions; Hot springs (105° to 108°), Bath co., Va.; Tuscan springs (76°), Shasta co., Cal.; Holston springs (60°), Scott co., Va.; and Lebanon springs, Columbia co., N. Y.—No complete analysis has yet been made of some valuable cold springs, such as the 16 Birchdale springs, near Concord, N. H., the waters of which are alterative, diuretic, and aperient; Parkersburg mineral wells, Wood co., W. Va., the principal constituents of which are sulphate of magnesia and sulphate of soda; Clarendon springs, Rutland co., Vt., used as a remedy in gravel, dyspepsia, and engorgement of the liver; Alleghany springs, Montgomery co., Va., and Shannondale springs, Jefferson co., W. Va., calcie waters. In F. V. Hayden’s “Preliminary Report of the United States Geological Survey of Montana,” &c. (Washington, 1872), Dr. A. C. Peale, the mineralogist of the expedition, gives a catalogue of the thermal springs met with, among which he enumerates 10 chalybeates, averaging 129°, near Ogden and the Great Salt lake, Utah; of calcaraceous springs, 5 in Lincoln valley, near Fort Hall, Idaho (75°), 6 in Madison co., Montana, 16 on Gardiner’s river, Wyoming, and 1 on the east fork of the Yellowstone (111° to 142°); 15 sulphurous and acidulous springs (151° to 171°) in the same tract; 6 sulphur and chalybeate springs (181°) on Yellowstone lake; 60 salses or mud volcanoes and sulphurous springs (178° to 184°) near Mt. Washburn and Túróld lake, Yellowstone valley; 17 salses (175° to 178°) on Crater hills and Steamy point, Yellowstone valley; 49 silicious (153° to 166°) on Yellowstone lake and Madison river; a great number of carbonated or soda springs (50°) on Bear river, Utah; and 400 geysers and silicious springs (157° to 184°) in the geyser basin of the National park.—Übersicht. Mineral waters are considered applicable to the treatment of chronic diseases only, as a rule, and are to be used during the inactivity of the disease. Medical advice is indispensable in their selection and use, as change of air, diet, &c., are important concomitants. Excesses of the table should be rigidly avoided during the treatment. The waters are usually taken before breakfast, the dose being gradually increased from one to four tumblers; but iron and alkaline waters may be taken several times a day, the latter with great advantage at bedtime. In some parts of France and Switzerland it is customary to drink while sitting in the bath, the usual time being two hours after breakfast. The stomach should be empty when the bath is taken. The regular temperature of the cold bath is 70°F. and below; of the warm bath, 92° to 98°; and of the hot bath, 105° to 110°. In the vapor and Russian bath the temperature is raised to 160°, and in the hot-air and the Turkish bath to 176°. The temperature of the body is so increased in these baths that the sudden transition to the cool shower bath and douche is soothing, and is followed under favorable conditions by copious perspiration. The mineral mud bath (85° to 100°) consists of mud taken from the marshy ground about the source of mineral springs. It is used chiefly in diseases of the skin, chronic rheumatism, and affections of the joints. When the symptoms of the “bathing crisis” appear, the use of mineral waters should be discontinued for a few days. A “small” or short cure requires three or four weeks, a “great” one five or six weeks. Mineral waters can be taken with benefit at any time of the year, but the season generally begins in May or June, and ends, according to the local climate, in September or October. After a season at the springs, the vineyards of Bingen, Dürkheim, Vevey, Montrex, and Meran are resorted to by many patients for an additional grape cure, the effect of which is generally cathartic.—For accounts of the mineral springs of Europe, see Durand-Fardel and E. Le Bost, Dictionnaire des eaux minérales (Paris, 1860); Althaus, “‘The Spas of Europe”’ (London, 1862); and in German, the works of Garless (1848), Posner (1856), and Lorsch (1855–60). Weller (1861), who also publishes a yearly guide, Wegweiser, H. Helft (1860), Braun (1869), T. Hirsfeld (Der Our-Salon, 1866–72), and R. Rentwigt (Badezeitung, 1869–72). For the springs of the United States, see Bell, “Mineral and Thermal Springs of the United States and Canada” (1855), and Walton, “The Mineral Springs of the United States and Canada, with Analyses and Notes of the prominent Spas of Europe” (1870).

MINERAL WATERS: Artifical, imitations of mineral spring waters, made by dissolving the salts which constitute the basis of the natural mineral waters in ordinary water impregnated with gases, especially carbonic acid gas. Experiments in their manufacture were made as early as the 16th century, but they have been produced in perfection only within the past 50 years, since chemical analysis has become an operation of minute exactness. The merit of the discovery of their principles belongs to
MINERAL WATERS

Berzelius and the German physician Struve; but the latter, who proved the practical value of the invention, and founded, as Berzelius did in Stockholm, the first manufactories or spas in Dresden (1818-20), Leipsic, Hamburg, Berlin, St. Petersburg, and Brighton, is deservedly called the father of artificial mineral waters. By powdering the clinkstone of Bilin and subjecting it to the action of carbonic acid water, under a slight hydrostatic pressure, he produced a mineral water identical with that of the natural spring of Bilin. Faraday and Liebig pronounced his artificial Carlsbad and Friedrichshall bitter waters to be identical in chemical composition and physiological action with the natural waters which they represented.

Artificial mineral waters have some advantages over natural waters. The supply of the latter exported from the springs of continental Europe is inadequate for the demand, and most natural waters lose materially by bottling. The springs too are subject to many changes, and frequently vary in the quantity or the relative proportion of their mineral ingredients. Artificial waters, on the contrary, are prepared according to analyses which represent the natural mineral waters when in their best condition. They are always the same in composition, in consequence of the technical perfection of their manufacture, and they produce the same general effect as the natural waters. They are more highly charged with carbonic acid gas than the latter, which insures their keeping in any climate and renders them more pleasant to the taste. The manufacture of mineral waters also embraces composition waters, devised for special medical purposes, and the beverages soda water, seltzer water, &c. The most important constituent of all these waters is carbonic acid gas, which is prepared by decomposing carbonates of lime and bicarbonates of soda with acids, especially sulphuric acid, in a vessel called the generator. Carbonates of lime contain from 41 to 52 per cent. of carbonic acid; bicarbonates of soda, 47-52 of soda and 52-38 of carbonic acid. Distilled water is used in making mineral waters, pure well or spring water for soda water, &c. Water absorbs nearly its own volume of carbonic acid gas at 60° F., and the absorption is increased by reduction of temperature, increase of pressure, or both. The principal substances or solids used in the manufacture of mineral waters are comprised in the following groups: 1. chlorides of magnesium, calcium, strontium, and lithium, carbonate of lime and of magnesia, and sulphate of magnesia; 2. the alkaline salts; 3. the salts of iron and of manganese. Waters containing sulphuretted hydrogen gas can never be perfectly imitated, because the formation of this gas is a continual process of decomposition, originating from the reaction of organic matter upon the sulphates. In the construction of the manufacturing apparatus two different systems are followed: 1. The Geneva system, an improvement of Struve's original apparatus. In this the carbonic acid gas passes from the generator through purifying vessels or bottles containing partly water, partly certain solutions of salts, and thence into the gasometer, out of which it is pressed by a pump into the mixing cylinder, where the water is impregnated with it. Between the pump and the cylinder is placed the repurgator, a cylindrical tube of strong sheet copper containing fine charcoal, in which the gas undergoes a final purification. The water is then impregnated with the gas by revolving a paddling shaft which passes through the middle of the mixing cylinder. The latter is provided with a manometer which indicates the pressure of the gas, tubes through which the water enters, a safety valve, and a water gauge. Bramah's apparatus is of similar construction, but has some improvements. In it the water to be aerated and the expanded carbonic acid gas are pumped in the proper proportions into the receiving vessel, where they are mixed and the aeration completed. This system is more generally in use in England and France than in Germany. 2. The self-generator system, after which the apparatus of Ozouf, Gappard, and Sauvresse are constructed. It dispenses with the pump and gasometer, the water being impregnated by the pressure of the gas itself. The generator which contains the carbonates is filled with hot water to a certain height, and a square cooling apparatus is therefore applied between the washing vessels and the cylinder. This apparatus is not so expensive as the former, but is less recommended on account of the imperfect purification of the gas and its liability to explosion. The apparatus of Mr. John Matthews of New York, which is now widely introduced in Europe, is a combination of the Bramah and the self-generator systems, the mechanical device of the former being greatly simplified, and the liability to explosion of the latter being obviated by a safety cap. This cap consists of a duplex disk, α, a nut, β, screwed firmly against it, a lead washer, γ, to close joint on the generator bung, and an aperture, δ, through which the gas escapes when the disk is ruptured by undue pressure.—After the mineral water is made, it is drawn from the apparatus into fountains (portable cylinders), siphons, or bottles, the faucets and filling and corking apparatus being so constructed as to prevent the loss of carbonic acid. For use, the fountains, which resemble the mixing cylinder in construction, are placed as reservoirs under or behind the marble case on the counter. The case contains ice in a cooling chamber, through which the connecting pipes

Matthews's Apparatus.
MINERAL WATERS

from the fountains pass to the faucets in front. The business of furnishing aereated waters in portable fountains has greatly increased since the improvements made by Matthews in the apparatus. The fountains previously in use were superficially coated with a wash of tin, and the contents were sooner or later contaminated by poisonous metallic salts. The Matthews fountains are composed of an inner container ofpure sheet tin secured in a shell of fine cast steel. Although much lighter than the old style of fountains, the 15-gallon fountain weighing but 40 lbs., they will resist a pressure of 500 lbs. to the square inch; and the connections being made of solid tin encased in sustaining sheets, the water cannot be contaminated. There are now 10,000 of these fountains in use, furnishing 4,000 places for dispensing aereated waters. The most perfect and elegant dispensing apparatus, in which the sirups are contained in portable glass tanks where they do not come into contact with any metal, are now made in the United States and extensively exported to Europe. An important and novel improvement in bottling aereated beverages, an American invention, in which the bottle is closed from the inside by a glass stopper, has recently come into extensive use both in the United States and in Europe.—Soda water proper is a solution of carbonate of soda in water, impregnated with carbonic acid gas. Webb’s English soda water contains 16 grains ofcrystallized carbonate of soda in one pint of water. Chloride of sodium is frequently added. Bicarbonate of soda is sometimes used for generating carbonic acid gas, and from this has arisen the popular use of the name soda water for carbonic acid water, or water charged with an excess of carbonic acid. German and American soda water, or what is called in France eau de selte, contains no soda. Priestley first produced it by pouring dilute sulphuric acid over carbonate of lime, and impregnating the water with the gas by a method which is still generally followed. Under the name of soda, carboionic acid water is mixed with sirups, and it forms a constituent of many of the American compound drinks. In Paris it is taken as eau gazeuse with hock and claret. Carbonic acid water improves the taste and increases the sanitary effect of drinks, is the best antidote for alcohol, and lessens the desire for spirituous liquors. It has a generally exhilarating and invigorating effect upon the system, essentially promotes digestion, checks too great acidity in the stomach, and is a much esteemed remedy in febrile diseases. Native wines are now extensively aereated in the United States, and American sparkling wines produced which will compare favorably with the best imported brands. This has been done only since the introduction of Matthews’s apparatus, in which the receivers and all the parts that come into contact with the wine are lined with pure silver, a metal which does not affect it unfavorably. Mineral waters have recently been brought from the most celebrated natural springs to New York in casks lined with pure tin sheets and aereated. Large quantities thus prepared are bottled or dispensed from fountains, and this trade is supplanting to a certain extent the manufacture of artificial mineral waters.—The great therapeutic value of baths in carbonic acid water (champagne baths) is now established. They produce a pleasant burning sensation in the skin, give elasticity to the limbs, and are generally invigorating if used moderately. They are produced by adding to 10 or 15 gallons of water at 110° F. an equal quantity of very strong carbonic acid water from a highly charged fountain, the escaping gas being finely divided by means of an apparatus constructed for that purpose. Chloride of sodium and of magnesium are added for brine baths.—See Carl Schulte, “Review of the History of Mineral Waters.” (New York, 1865).

MINERSVILLE, a borough of Schuylkill co., Pennsylvania, on the W. branch of the Schuylkill river and on the Mine Hill and Schuylkill Haven railroad, 4 m. W. of Pottsville, and 46 m. N. E. of Harrisburg; pop. in 1870, 3,699. It is surrounded by hills containing rich mines of anthracite, and has a national bank, a flour mill, saw mill, iron foundry, car factory, nine public schools, with a high school, a weekly newspaper, and four churches.

MINERVA, called by the Greeks ATHENA, PALLAS, or Pallas Athene, in mythology, one of the principal Olympian divinities. She was one of the most ancient religious conceptions of the Greeks. Jupiter, after a victory over the Titans, chose for his first spouse the goddess Metis; but an oracle having declared that the son of Metis would snatch the supremacy away from his father, Jupiter swallowed both Metis and her unborn child. When the time of birth arrived, Jupiter felt a violent pain in his head, and in his agony requested Vulcan to which were the head. Whereupon Minerva sprang forth, according to the later accounts, in full armor, and with a mighty war shout. She first took part in the discussions of the gods as an opponent of the savage Mars. She gave counsel to her father against the giants, and herself slew Pallas and Ececludus, the latter of whom she buried under Mt. Etna. She was the patron of heroism among men, and aided the Greeks in the Trojan war. As a protectress of the arts of peace, she appears as a maiden, in many respects resembling a princely daughter of the early heroic period. She bears in her hand the spool, the spindle, and the needle, and is said to have invented and executed in every kind of work proper to women. The agriculturist and the mechanic were also under her care, and the philosopher, the orator, and the poet delighted in her protection. In all these employments she is the symbol of thought, the goddess of wisdom; and as such she was worshipped throughout Greece, and under the
name of Minerva she was adopted by the Romans. She was especially the national divinity of the Athenians, having in the reign of Cecrops contended with Neptune for the land, which she planted with the olive. On the Acropolis of Athens stood the magnificent temple of the Parthenon, dedicated to her, and containing her statue by Phidias; and the sacred festival of the Panathenaea was celebrated with great splendor in her honor. In the representations of art, as in the events of her life, she remains the goddess of pure reason, raised above every feminine weakness, and disdaining love. The helmet, buckler, lance, and segis were her attributes; and the olive branch, serpent, and owl were sacred to her. In the ancient traditions she was represented as clothed usually in a sleeveless tunic, over which she threw a cloak, or folding peplos. 

MINGHETTI, Marco, an Italian statesman, born in Bologna, Sept. 8, 1818. He early became known as a lecturer on political economy and advocate of free trade, and as a journalist. In 1848 he was for a short time minister of public works at Rome, but he left the service of Pius IX. to enlist in the Sardinian army, in which he rose to be major. He assisted Cavour at the congress of Paris in 1856, and published in 1859 *Della economia pubblica e delle sue attinenze con la morale e col diritto.* He was next secretary general in the ministry of foreign affairs, and subsequently, as a member and president of the assembly of the Romagna, he was active in the annexation of those provinces to the dominions of Victor Emanuel. Afterward he represented Bologna in the national parliament. Shortly before Cavour's death he became minister of the interior, and retained that office for a short time under Risoli. From 1868 to 1869 he was premier, minister of finance; and after being minister to England he accepted in 1869 the portfolio of agriculture, and in 1873 succeeded Lanza as prime minister. In the elections of November, 1874, he was once more returned to parliament. He has been long engaged upon a work on Europe before the reformation.

MINGRELLIA, a district of Asiatic Russia, in the lieutenancy of the Caucasus, forming part of the government of Kutais, bordering on the Circassian districts, Imerethia, Guria, the Black sea, and Akhassia; area, about 2,600 sq. m.; pop. about 240,000, or, including Sameteli and Samurzakan (together 1,500 sq. m.), which are embraced in the same government, 280,000. The surface is generally mountainous, but slopes gradually to the south, particularly toward the Rion, its principal river. The climate is warm and damp, and fevers are prevalent. The soil is exceedingly fertile and vegetation rapid. The mountains are covered with magnificent forests, and much good lands lies waste. The principal products are maize, wood, wax, and wool. Tobacco, rice, and millet are raised, and a good deal of silk, honey, and wine produced. There is an iron mine and a smelting furnace, and in 1865 gold was discovered in the valley of the Ingar. The district is without internal improvement, and has a savage and deserted appearance. The inhabitants belong mainly to the Georgian race, but are generally inferior in appearance to the mountaineers of the Caucasus. The dominant religion is that of the Greek church. — Mingreli'a nearly corresponds with the ancient Colchis. It was long a part of the kingdom of Georgia, was afterward independent under a line of native princes, and became subject to Russia in 1804; but its prince remained nominally sovereign till Jan. 17, 1897, when he ceded all his rights to the emperor of Russia in consideration of 1,000,000 rubles. On the W. coast the Russians have established the forts of Redut-Kaleh and Anakilia. 

MINHO (Sp. Miño; anc. Minius), a river of Spain and Portugal, which rises in the Sierras de Mondofiedo, in the province of Lugo, Galicia, a short distance S. of Mondofiedo, flows first S. and then S. W., crosses the province of Orense, forms the boundary between the Spanish province of Pontevedra and the Portuguese province of Minho, and falls into the Atlantic near Caminha, about 20 m. S. of V. do. It is about 150 m. long, and is navigable for only a short distance from its mouth, being obstructed by sand banks. It abounds in salmon and lampreys. Its principal tributaries are the Sil, which joins it on the left about 70 m. from its mouth, and the Avia on the right. The largest towns on its banks are Lugo and Orense in Spain. 

MINHO, or Entre Douro e Minho, the northernmost province of Portugal, bounded N. by the Spanish province of Pontevedra, from which it is separated by the Minho, N. E. by that of Orense, E. by the Portuguese province of Tras-os-Montes, W. by the Douro, on which it is separated by the Douro, and W. by the Atlantic; area, 2,807 sq. m.; pop. in 1871, 971,000. It is a high table land intersected by several mountain ridges, running in a N. E. and S. W. direction, one of which rises to the height of nearly 8,000 feet. The principal rivers are the Lima, Cavado, and Ave, which flow into the sea, and the Tamega, an affluent of the Douro; there are also numerous smaller rivers and streams, and the valleys are exceedingly fertile and well cultivated. The principal productions are wine, millet, oil, flax, cork, oranges, lemons, maize, tobacco, barley, and oats. The well known wine called port from Oporto, whence it is shipped, is almost wholly made in this province. Numerous herds graze the pastures, and the province is famous for its pork. The sea and rivers abound with fish, the capture of which affords employment to many of the inhabitants. The principal manufactures are linen, hats, and cutlery. The population of this province is the most intelligent and prosperous portion of the Portuguese people. Capital, Braga. 

MINIATURE PAINTING, a species of painting on a small scale, executed with water colors.
on vellum, prepared paper, or ivory, or in enamel. The word originated from the ancient practice of writing the initial letters of manuscripts in minium or red lead, for the purpose of distinguishing the commencement of chapters or paragraphs. These rubies, as they were called, gradually received many fanciful adornments at the hands of the illustrators, who added rich arabesque borders, and finally delicately executed little pictures illustrating the text, to which the general name of miniature was applied. The taste for this species of ornamentation existed at a period considerably anterior to the Christian era. The ancient Egyptians illuminated their papyri with colored hieroglyphics; and from passages in Pliny, Seneca, and other classical authors, the art seems to have been familiar to the Greeks and Romans. The middle ages, however, and especially the period extending from the 8th to the 14th century inclusive, witnessed its most perfect development; and the medieaval monks in the solitude of their convents found at once an amusement and a pious occupation in embellishing their missals, breviaries, and other sacred volumes. The illumination of missals was consequently for many ages the chief form in which miniature painting was practised, although, as in the case of fresco and oil paintings, subjects other than Scriptural or sacred were from the outset occasionally selected. The art seems from an early period to have been divided into two branches, the professors of the first being called miniator or miniature painters, or illuminators of books; and those of the second miniator caligrafi, or calligraphers. "To the first class," says Mrs. Merrifield, "belonged the task of painting Scripture stories, the borders, and the arabesques, and of laying on the gold and ornaments of the manuscripts. The second wrote the whole of the work, and those initial letters, generally drawn with blue or red, festoons of flowers and fanciful ornaments, in which the patience of the writer is frequently more to be admired than his genius." Sometimes, however, the two branches were practised by the same person, and about the middle of the 14th century the execution of large illuminated initials adorned with various fanciful objects and figures, such as men, animals, birds, and flowers, became a distinct occupation, the ornamentation usually extending in scrolls along the upper and lower margins of the page. The pigments employed were of the purest quality, and were applied with an admixture of white in the shape of body colors, the vehicle being some glutinous substance sufficiently diluted in water to leave the surface of the vellum dull and lustreless. The Vatican collection of manuscripts contains one of the most ancient specimens of classical calligraphy extant, a Virgil of the 4th or 5th century with 50 miniatures, besides many others of some what later date; and fragments of an illuminated Homer, which may also be ascribed to the 4th or 5th century, are preserved in the Ambrosian library at Milan. The Byzantine artists particularly excelled as illuminators, and their manuscripts exhibit intricate arabesques of mixed foliage and animals, and the richest architectural fancies in the margins, although many of these are said to be repetitions of Romano-Christian works of the 5th and 6th centuries. The most elaborate exemplar of the school is the Menologium, or calendar executed about A.D. 1000 for the emperor Basil II, and which, notwithstanding one half of it is wanting, contains 430 miniatures on a gold ground, illustrating scenes from the lives of Christ and the saints, the history of the church, &c. The period extending from the middle of the 11th to the commencement of the 13th century was the richest in the history of the Byzantine school. Afterward the art rapidly deteriorated and was lost for a time. Under the early Carolingian kings of France, the transcription and embellishment of manuscripts were greatly encouraged; and the Bibles of Charles the Bald, preserved in the imperial library at Paris, and in the Benedictine monastery of St. Caixtus in Rome, are admirably illustrated. The English manuscripts are not inferior to the continental, and the benedictional of St. Ethelwol, executed in 963-7 by Godeman, a monk of Hyde abbey, is considered one of the purest specimens of early English art. The celebrated Bede missal, executed in France for John, duke of Bedford, regent of France under Henry VI., and now in the British museum, is one of the latest and richest specimens of the art of manuscript illumination. Among the most celebrated of the miniator, who were also equally if not more celebrated in other branches of art, may be mentioned Simone Memmi, Giotto, Fra Angelico da Fiesole, Jan van Eyck, Squarcione, Girolamo dal Libri, Hans Memling, and Giulio Clovio. Memling was principally the artist of all the illuminators; and of the industry of Giulio Clovio a memorable example is extant in his "Office of the Virgin," now in the royal library of Naples, the 28 miniatures of which are said to have occupied him nine years. With the invention of printing the occupation of the illuminator and calligrapher gradually ceased, although of late years the practice of embellishing books with illuminated borders and fanciful initials has again come into vogue. But modern invention has substituted for the toilsome efforts of the miniator of the middle ages various rapid processes for printing designs in colors, of which Owen Jones's publications afford some happy illustrations.—The term miniature painting is now applied almost exclusively to small portraits executed on thin sheets of ivory, which, on account of the semi-transparency of its texture, is preferred to any other material. This property of the ivory renders it necessary for the back to be protected by something perfectly white, as the effect of the painting might be injured by any dark substance showing...
through. Miniatures on ivory seldom exceed a few square inches in size. In England the art has been cultivated by an eminent line of artists from Holbein downward, embracing such names as Nicholas Hilliard, Isaac and Peter Oliver, Samuel Cooper, Hoskins, Flattman, Gibson, Cosway, Ross, Newton, Thorburn, &c., whose works are invaluable for the likenesses they afford of distinguished public characters. According to Dr. Waagen, "in no department have the English artists attained so high a state of perfection as in this." Under the first empire the French had many excellent miniaturists, including Isabey, who not only painted on ivory portrait pieces containing many figures, but attempted with success historical subjects; Augustin, Guérin, Saint, Mme. de Mirbel, &c. The most eminent American miniature painter was Malbone, whose works are executed with great delicacy, and after the lapse of many years retain much of their original freshness. Of late years the introduction of colored or retouched photographic likenesses has somewhat interfered with the profession of the miniature painter; but these, owing to their perishable nature, can never wholly supplant portraits on ivory. Photography, regarded simply as an auxiliary to the miniature painter, rather aids than injures him by the data it affords for greater accuracy of drawing and proportions. (See Enameling.—See "Original Treatises on the Arts of Painting in Oil, Miniature, Mosaic," &c., edited by Mrs. Merrifield (2 vols., London, 1849).

MINIE, CLAUDE ÉTIENNE, a French inventor, born in Paris about 1803. At an early age he entered the army as a private soldier, and, after serving several campaigns in Algeria, reached the rank of captain. He now began to study improvements in firearms and projectiles; and on the supposition that he was from this cause losing his efficiency as a military officer, his dismissal was determined upon. Through the influence of the duke de Montpensier he was retained in the service, and gradually several of his improvements in rifle balls, cartridges, and gun barrels were adopted. In 1849 he was decorated with the cross of the legion of honor; in 1852 he was promoted to the rank of major on the retired list, and soon after was appointed chef du tir, or instructor in the use of firearms, at Vincennes. In 1858 he resigned this post, and was appointed by the Egyptian government to superintend a manufactury of arms and a school of gunnery at Cairo. The rifle bullet named after him is said to have been the invention of his friend and instructor, Capt. Deligne. It consists of an elongated cylinder, conical in front and hollow behind, and fitted with a cap of thin iron, which, by filling the grooves of the barrel as the ball is forced through, gives to the latter a precision and range of flight previously unknown to gunnery. This was the first effectual introduction of the principle of expansion into the manufacture of firearms.

MINIUM. See Lead, vol. x., p. 245.

MINK, a small, fur-bearing, carnivorous mammal, found in the northern parts of America, Europe, and Asia, belonging to the genus _Putorius_ (Cuv.), in which are included the ermine and common weasels, and to the sub-genus _Lutreola_ (Wagner). The minks have one molar less on each side above and below than the martens (Mustela), and are therefore more carnivorous; the size is smaller, and the form more slender; the color is nearly uniform; the feet much webbed, and their pads large and naked, with the intervals not occupied by hairs. The common American mink (_P. vison, Rich._) varies in length (from nose to base of tail) from 13 to 18 in., the tail being 8 to 10 in. additional; the general color is dark brownish, the tail nearly black, the chin white, but not the edge of the upper jaw; some specimens are lighter, even to yellowish brown; the head is broad and depressed, with truncated snout, short round ears, eyes small and far forward, long and rigid whiskers in four horizontal series; body long and vermiciform, with long neck; short and stout limbs, with five-toed feet, armed with sharp claws; tail long and cylindrical, having on each side of the under surface a glandular cavity secreting a strong musky fluid, whence the generic name;
about 50 cents; but change of fashion afterward brought it into vogue and made it very valuable; it is fine, but shorter and less lustrous than that of the pine martens or American sable. (See FUR.) The animal is very generally distributed in North America, from lat. 70° N. to Florida, and from ocean to ocean. Some specimens from the west are larger than the average. In the northern states there is a smaller and blacker variety; the fur is dark and remarkably soft, and considerably more valuable than that of the common mink. —The European mink (P. lutreola, Cuv.) is of smaller size, darker colored, with less bushy tail, and the edges of the upper lip white; it is a rare animal, with the same habits as the American species, and its fur is more highly esteemed; indeed it is often sold to the inexperienced for sable, and that of the American mink is generally called by furriers American sable, though the latter belongs to the genus Mustela and is properly a marten.

MINNEAPOLIS, a city and the county seat of Hennepin co., Minnesota, on both sides of the Mississippi river, here spanned by four bridges, at the falls of St. Anthony, 14 m. above St. Paul by the course of the stream, and 8 m. in a direct line W. N. W. of that city. (pop. within its present limits) in 1860, 5,822; in 1870, 18,079, of whom 6,013 were foreign; in 1874, estimated by local authorities at 32,000. It is built on a broad natural esplanade overlooking the falls and the river, which is bordered at various points by picturesque bluffs. The surrounding country is remarkable for its beauty. Numerous lakes, particularly to the west, dot the landscape. The chief of these are Cedar, Calhoun, and Harriet, S. W. of the city. The celebrated Minnehaha falls, 3 m. below, attract large numbers of visitors. A cemetery association which was organized in 1871 has selected 128 acres between Lakes Calhoun and Harriet as the site for a cemetery. These grounds are covered with groves of young trees, and command fine views of the lakes. The city is regularly laid out, with avenues running E. and W. and streets crossing them N. and S. They are generally 80 ft. wide, with 20 ft. sidewalks, and two rows of trees on each side. There are many substantial business blocks and elegant residences. The court house, city hall, two principal hotels, academy of music, opera house, and Athenaeum are noticeable structures. The city is supplied with water by powerful works, the streets are lighted with gas, and a system of sewerage is in process of construction. The Chicago, Milwaukee, and St. Paul railroad has its terminus here. The St. Paul and Pacific, and the Lake Superior and Mississippi railroads, with the Minneapolis and St. Louis line, connect the city with the Northern Pacific railroad, with Duluth, and with St. Paul and the diverging lines. A line of steamers in summer runs from above the falls to St. Cloud on the upper Mississippi. —The wholesale trade of Minneapolis is important and constantly increasing. There are four large groceries, doing a business of from $4,000,000 to $5,000,000 a year, several hardware and iron houses, and three large dry-goods stores. The total commercial business in 1873 amounted to $14,501,700; in 1871 it was $10,530,000. There were five national banks and six private and savings banks in 1873, with an aggregate capital of $1,025,000, and loans, discounts, and exchange to the amount of $14,682,400. The amount of freight forwarded by rail in 1873 was 892,480,329 lbs.; received, 263,943,760 lbs.; being an increase over 1872 in receipts and shipments of 80,682,550 lbs. The falls of St. Anthony, having a perpendicular descent of 18 ft. and a total descent of 50 ft. within the space of a mile, afford abundant water power for manufacturing. The two principal items of manufacture are lumber and flour. There are 18 lumber mills, with an aggregate capital of $1,110,000; hands employed in 1873, 2,062; feet of lumber manufactured, 189,909,792; shingles, 114,554,250; lath, 32,843,150; pickets, 546,373; total value of products, $3,880,000. At the close of 1873 there were 18 flouring mills, with 150 run of stone and a daily capacity of 7,370 barrels, and others in course of erection which would increase the stone to 184 run and the capacity to 9,200 barrels a day. One of the mills, with 40 run of stone, is the largest in the country. The number of bushels of grain ground in 1873 was 3,545,000; barrels of flour produced, 646,000; pounds of feed, 57,050,000; total value of products, $4,842,920. At the two grain elevators 1,687,425 bushels of wheat were handled in 1873. A third elevator, larger than either of the others, is in course of construction. There are extensive works for the manufacture of engines, boilers, water wheels, ploughs, harvesters, &c.; several manufacturers of sash, doors, and blinds, four of furniture and desks, seven of barrels, seven of boots and shoes, five of saddlery and harness, two of bricks, two of soap, nine of carriages and wagons, one of linseed oil; several breweries, two paper mills, a cotton mill, and a woolen mill. There is also a pork-packing establishment, and the Chicago, Milwaukee, and St. Paul railroad has here extensive machine and repair shops. The number of hands employed in manufacturing in 1873 was 3,920; value of all products, $13,879,680; amount of capital invested, $16,000,000. The number of hands employed in 1867 was 1,841; value of products, $4,460,358. The amount expended in the city in building and improvements in 1873 was $1,729,700; taxable value of property, May 1, 1874, $26,947,969. —Minneapolis is divided into ten wards, and is governed by a mayor and a board of aldermen of two members from each ward. It has a municipal court and an efficient police force and fire department. It is the seat of the state university, which occupies
large buildings on the E. side of the river. (See Minnesota, University of.) Augustana theological seminary (Evangelical Lutheran) was organized in 1869 by Scandinavians. In 1873-4 it had 5 professors and instructors, 63 students, and a library of 1,100 volumes. There are also an academy, a female seminary, and a business college. The Methodists are erecting (1875) a large edifice near the city for Hamline university, soon to be organized. The public schools embrace the various grades from primary to high school. There are ten school buildings of brick and stone. The number of departments in 1873 was 35; teachers, 37; pupils enrolled, 2,298; average attendance, 1,866. The Athenaeum library contains 4,000 volumes. There are two daily and nine weekly (two Norwegian and one German) newspapers, and two semi-monthly (one Norwegian) periodicals. The number of churches is 48, viz.: 5 Baptist (1 African and 1 Swedish), 1 Christian, 5 Congregational, 4 Episcopal (besides 2 missions), 1 Freewill Baptist, 1 Friends, 7 Lutheran (3 German Evangelical, 3 Norwegian, and 1 Swedish Evangelical), 11 Methodist (1 African, 2 German, and 1 Scandinavian), 4 Presbyterian, 4 Roman Catholic, 1 Swedish, 1 Unitarian, and 3 Universalist.—Minneapolis was first settled in 1849, and originally embraced only that portion of the city on the W. bank of the Mississippi. It was incorporated in 1867, and in 1872 the city of St. Anthony on the E. bank of the river (incorporated in 1856) was consolidated with it.

Minnesota, a S. E. county of Dakota, bordering on Minnesota and Iowa, and drained by the Big Sioux river; area, 816 sq. m.; pop. in 1870, 355. The surface is elevated, and the soil productive. Capital, Sioux Falls.

Minnesingers (Ger. Minne, love, and Singer, singer), a school of German poets which sprung into existence in the latter half of the 12th century, and flourished until near the close of the 13th. Their themes were amatory and heroic, and were treated in much the same manner as those of the troubadours of Provence, though in a more earnest spirit and after a purer ideal conception of love. (See Germany, Literature of, vol. vii., p. 763.)

Minnesota, one of the northwestern states of the American Union, the 19th admitted, and the 28th in rank according to population, situated between lat. 43 deg. 30' and 49 deg. 24' N., and long. 89 deg. 39' and 97 deg. 5' W.; extreme length N. and S., 380 m.; breadth from 188 m. in the middle to 262 m. on the S. line and 337 m. near the N. line; area, 83,531 sq. m. It is bounded N. by British America, the dividing line being formed W. of the lake of the Woods by the 49th parallel, and E. of that lake by Rainy Lake river, Rainy and other lakes, and Pigeon river; E. by Lake Superior and Wisconsin, from which it is separated by a line drawn due S. from the first rapids in the St. Louis river to the St. Croix river, and by the St. Croix and Mississippi rivers; S. by Iowa; and W. by Dakota, from which it is divided by the Red river of the North, the Bois des Sioux river, Lake Traverse and Big Stone lake, and a line drawn directly S. from the outlet of the last named lake to the Iowa boundary. The state is divided into 76 counties, viz.: Aiken, Anoka, Becker, Beltrami, Benton, Big Stone, Blue Earth, Brown, Carlton, Carver, Cass, Chippewa, Chisago, Clay, Cook, Cottonwood, Crow Wing, Dakota, Dodge, Douglas, Faribault, Fillmore, Freeborn, Goodhue, Grant, Hennepin, Houston, Isanti, Itasca, Jackson, Kanabec, Kandiyohi, Lac qui Parle, Lake, Le Sueur, Lincoln, Lyon, McLeod, Martin, Meeker, Mille Lacs, Morrison, Mower, Murray, Nicollet, Nobles, Olmsted, Otter Tail, Pembina, Pine, Polk, Pope, Ramsey, Redwood, Renville, Rice, Rock, St. Louis, Scott, Sherburne, Sibley, Stearns, Steele, Stevens, Swift, Todd, Traverse, Wabasha, Wadena, Wasca, Washington, Watonwan, Wilkin, Winona, Wright, Yellow Medicine. St. Paul, the capital, near the E. border of the state, 400 m. N. W. of Chicago, had 20,030 inhabitants in 1870. The other cities, according to the census of 1870, were: Duluth, 3,131 inhabitants; Hastings, 3,458; Mankato, 3,482; Minneapolis, 13,966; Owatonna, 2,076; Red Wing, 4,260; Rochester, 3,958; St. Anthony, 5,015; St. Cloud, 2,161; and Winona, 7,192. Since the census St. Anthony has been annexed to Minneapolis.—The population of Minnesota was 6,077 in 1850, 172,023 in 1860, 250,099 (state census) in 1865, and 439,706 in 1870, including 438,257 white, 759 colored, and 690 Indians. The calculated population on June 1, 1873, was 552,459. Of the total population in 1870, 395,299 were males and 204,076 females, and 279,069 were of native and 160,697 of foreign birth. Of the natives, 125,491 were born in the state, 10,979 in Illinois, 5,998 in Maine, 39,507 in New York, 12,651 in Ohio, 11,966 in Pennsylvania, and 24,048 in Wisconsin. The foreign population comprised 16,098 born in British America, 1,910 in Denmark, 1,748 in France, 41,364 in Germany, 5,670 in England, 21,748 in Ireland, 2,194 in Scotland,
MINNESOTA

1,865 in Holland, 35,940 in Norway, 20,987 in Sweden, and 2,162 in Switzerland. The density of population was 5.26 to a square mile. There were 82,471 families with an average of 5.33 persons to each, and 81,140 dwellings with an average of 5.42 persons to each. The increase of population from 1860 to 1870 was 155.61 per cent., being a greater percentage of increase than that of any other state, except Kansas. The number of male citizens 21 years old and upward was 75,274; of persons from 5 to 18 years of age, 142,665; attending school, 96,738. There were 12,747 persons 10 years of age and upward unable to read, and 24,413 unable to write; of the latter, 5,558 were of native and 18,856 of foreign birth; illiterates, 7.99 per cent. of the population 10 years old and over; number of illiterates 21 years of age and upward, 18,484, of whom 8,106 were males and 10,378 females. The number of paupers supported during the year ending June 1, 1870, was 684, at a cost of $66,167. Of the total number (392) receiving support June 1, 1870, 126 were natives and 266 foreigners.

The number of persons convicted of crime during the year was 214; in prison at the end of the year, 129, including 73 natives and 56 foreigners. The state contained 103 blind, 166 deaf and dumb, 925 insane, and 134 idiotic. Of the total population 10 years old and over (308,568), there were engaged in all occupations 133,637; in agriculture, 75,157, including 20,277 laborers and 54,623 farmers and planters; in professional and personal services, 28,330, of whom 620 were clergymen, 8,556 domestic servants, 13,087 laborers not specified, 449 lawyers, 402 physicians and surgeons, and 1,754 teachers not specified; in trade and transportation, 10,582; and in manufactures and mechanical and mining industries, 18,588. The total number of deaths from all causes was 9,326, being 0.962 per cent. of the population. There were 4,382 deaths from diseases, being 7.7 deaths per 1,000 from all causes to 1 from that disease; 177 from pneumonia, 19.9 from all causes to 1 from that disease; 112 from diarrhea, 108 from cholera infantum, and 103 from whooping cough. The number of deaths reported by the state authorities in 1872 was 5,238, or 1.085 per cent. of the population. Of the whole number of deaths, 36.07 per cent. were from zymotic diseases, 18.00 constitutional, 18.01 local, 10.94 developmental, 4.72 violent deaths, and 17.04 unknown. The excess of births over deaths was 9,734. At the beginning of 1875 there were 6,973 Indians reported in Minnesota, who were settled on reservations in the central and northern parts of the state. They consisted of seven bands of Chippewas, with three agencies at White Earth, Leech lake, and Red lake. These Indians have schools and are for the most part occupied in agriculture.—Lying nearly at the centre of the continent and occupying the most elevated plateau between the gulf of Mexico and Hudson bay, Minnesota forms the water-shed of the three great river systems of North America: that of the Mississippi, which flows S. to the gulf of Mexico; that of the St. Lawrence, which, connected with the chain of northern lakes, has an easterly direction to the Atlantic ocean; and that of the Red river of the North, flowing N. to Winnipeg lake, which has its outlet in Hudson bay. A group of low sandhills in the N.W. part of the state, formed by huge deposits of drift overlying a local outcrop of the primary and metamorphic rocks, and called Hauteurs des Terres, forms the dividing ridge between the Mississippi and Lake Superior. The Heights of Land rise by scarcely perceptible slopes from the general level, in no instance higher than 1,000 ft. above the sea, which is not more than 600 ft. above the average elevation of the country. These hills are commonly flat to the top, varying in height from 5 to 100 ft. above the surrounding waters. The principal group of these drift hills is sub-divided into several ramifications. A prominent spur extends southerly from the Itasca crest of the Mississippi for perhaps 150 m., known as the Leaf mountains and the Coteau du Grand Bois of Nicollet, and forms a low dividing ridge between the waters of the Mississippi and Red rivers. The crest of the dividing ridge between Lake Superior and the Mississippi is not more than 1,400 ft. high; and the highest of the trap summits north of the lake is but 1,475 ft. Generally the surface of Minnesota is an undulating plain, with an average elevation of nearly 1,000 ft. above the sea, and presents a succession of small rolling prairies or table lands, studded with lakes and groves, and alternating with belts of timber. Two thirds of the surface slopes S. E. with the waters of the Mississippi, the northern part of the state being nearly equally divided between the alluvial levels of the Red river valley on the northwest and the broken high lands of the northeast which are mainly drained by the precipitous streams which flow into Lake Superior and the Rainy lake chain.—The Mississippi river rises in Lake Itasca in the extreme western elbow of the Heights of Land, and flows S. E., 797 m. of its course belonging to Minnesota, of which 184 forms the E. boundary; it is navigable about 540 m. within the state. The Minnesota traverses the lower part of the state in a S. E. and N. E. direction, and after a course through the state of 450 m. falls into the Mississippi at Fort Snelling, 5 m. above St. Paul; it is navigable about 300 m. The Red river of the North rises in Elbow lake, flows through several lakes, running in a S. W. direction, and then turning N. forms the W. boundary for 379 m.; it is navigable about 250 m. The St. Croix rises in Wisconsin, forms 129 m. of the E. boundary, and falls into the Mississippi; it is navigable for 33 m. In the N. E. part is the St. Louis river, which falls into Lake Superior, and is important as the first link in the chain of lakes and rivers of the St. Lawrence system; and in the S. W. are the head
waters of the Des Moines, about 183 m. long, of which about 50 are navigable. All the rivers have numerous branches, which are not navigable. The navigable waters within the state have a total shore line of 2,746 m., and a water line of 1,532 m. Along the banks of the Mississippi and of some other rivers are high bluffs, forming one of the most interesting and characteristic features of the scenery. Minnesota is distinguished for the number and beauty of its lakes. They have been estimated as high as 10,000 in number, and are from 1 m. to 30 m. in diameter; and many of them have an area of from 100 to 400 sq. m. Their waters, generally sweet and clear, abound in fish. The largest are the lake of the Woods, Rainy, Namekin, Bois Blanc, Vermilion, Swan, Sandy, Winibigoshish, and Leech lakes, and Mille lacs in the north and northeast, Red lake in the northwest, Big Stone, Benton, Sauk, and Swan in the west and southwest.—Notwithstanding the great area covered by this state, its rock formations, so far as they have been explored, appear to be limited almost exclusively to the azoic and lower protozoic groups; and over the greater part of the state these are concealed beneath the diluvial deposits which make the superficial covering of the rolling prairies. The N. W. coast of Lake Superior is made up of metamorphic slates and sandstones, intermingled with grits of volcanic origin and other bedded traps and porphyries. These are intersected by frequent dikes of greenstone and basalt; and among them are occasional deposits of red clay, marl, and drift. Behind this group are traced westward, along the northern boundary of the state, formations of hornblende and argillaceous slates, succeeded by granitic and other metamorphic rocks. These groups extend S. W. into the central portions of the state. Along the southern boundary the Devonian formation is found in the extreme west; the Niagara limestone succeeds this toward the east, and next occurs the Galena limestone, and then the Trenton limestone and the upper or St. Peter's sandstone, which overlies the Potsdam sandstone. These sandstones crop out up the valley of the Mississippi, nearly as far as Fort Snelling, where the lower Silurian limestones, which on both sides of the river lie behind and over the sandstones, meet in the valley and form the bluffs of the rivers. They are traced up the Minnesota river, curving round and almost reaching the southern boundary of the state again, and cutting off the continuation of the higher groups further northward. Thus throughout the state there appears to be no room for the carboniferous group. The lead-bearing rocks traced from the Iowa line are limited and of little importance. It is believed that the N. E. corner of the state will prove a valuable mineral field. Copper abounds in the mineral belt stretching along the N. shore of Lake Superior, and masses of the pure metal have been taken from Knife and Stuart rivers. Iron ore of good quality is found in considerable quantities around Portage and Pigeon rivers. Large deposits of peat exist in all parts of the state. In the Red river valley are extensive salt springs. Slate, limestone, sand for glass, and clay are also found. The existence of gold and silver on the shores of Vermilion lake has been shown. A geological and natural history survey of Minnesota is now (1875) in progress, under the direction of N. H. Winchell, state geologist, and S. F. Peckham, state chemist, professors in the state university, to which institution the survey has been intrusted by law. Up to 1875 a preliminary report and two reports of progress had been printed in the annual reports of the board of regents for 1873-5.—The soil is fertile, two thirds of the surface being well adapted to the cultivation of all the cereals and roots of the temperate zone. It is composed generally of a dark, calcareous loam, abounding in organic and saline ingredients, and is retentive of moisture. The climate of Minnesota is pleasant. The winters are cold, but clear and dry, and the fall of snow is light; the summers are warm, with breezy nights, during which occur most of the rains; and the general purity of the air and salubrity of its climate recommend it for the residence of invalids. The following summary for 1874, reported by the United States signal bureau, is for St. Paul, lat. 44° 53', lon. 93° 5':

The country, especially above lat. 46°, is well timbered; pine forests extend far to the north, and birch, maple, aspen, ash, and elm abound. A large forest of hard-wood varieties, known as the Big Woods, and called Bois Franche by the early French settlers, extends over the central portion of the state W. of the Mississippi, and covers an area of about 4,000 sq. m. On the river bottoms are found basswood, elm, aspen, butternut, ash, birch, maple, linden, balsam fir, and some oaks; and in the swamps tamarack, cedar, and cypress. Among the wild animals are the elk, deer; antelope, bear, wolverene, otter, muskrat, mink, marten, raccoon, and wolf. Of birds, there are the golden and bald eagles, grouse, partridge, hawk, buzzard, owl, quail, plover, lark, and many smaller kinds. There are also the pelican, tern, sheldrake, teal, loon, wild goose, wild ducks, and other water fowl. The waters contain pike, shovel-
MINNESOTA

605
pickeral, bass, whitefish, muskelonge, catfish, trout, and other varieties of fish.—Many natural objects of interest are found in the state. The Mississippi, studded with islands and bordered by ragged bluffs, presents a succession of picturesque scenes. Mountain island, with an elevation of 428 ft., Maiden’s rock, celebrated in Indian tradition, on an expansion of the river called Lake Pepin, about 400 ft. high, and La Grange mountain on the same lake, are all notable. St. Anthony’s falls, celebrated as much for their surrounding scenery as for the descent of the waters, which have a perpendicular fall of only 18 ft., are further up the river. A few miles beyond, between Minneapolis and Fort Snelling, are the Minnehaha falls, a romantic and beautiful cascade with a perpendicular pitch of 45 ft., flowing over a projecting rock which permits a passage underneath. Brown’s falls, which have a perpendicular descent of 50 ft., and including the rapids of 100 ft., are W. of the Mississippi, on a narrow stream which is the outlet of several small lakes. There are also falls or rapids on the St. Croix, about half a mile below which is a noted pass through which the river has forced its way, called the Dales of St. Croix, and others of less note on various streams. About 2 m. from St. Paul is Fountain cave, an excavation in the white sandstone, with an entrance about 15 ft. in diameter opening into a chamber 150 ft. long and 20 ft. wide. The cave has been explored for 1,000 ft., without the termination being reached.—Minnesota has made the most rapid progress in agriculture during the past few years. The most prominent staple is wheat, for the production of which the soil and climate are most favorable. Of the reported cultivated acreage in 1872, wheat occupied 61.14 per cent., the average yield per acre being 17.4 bushels; in 1873 the percentage of acreage had increased to 68.58. Next to wheat the most important crops are oats and corn, the percentage of acreage in 1872 being 19.97 of the former and 10.44 of the latter. The soil and climate are also highly favorable to wool growing. In 1860 Minnesota had 2,711,968 acres of land in farms, of which only 756,250 acres were improved, there being 15,181 farms with an average of 13 acres each. In 1870 there were 46,500 farms of an average of 139 acres each, the total acreage of farm lands being 2,322,102 improved and 4,161,756 unimproved, including 1,386,599 of woodland, the percentage of improved land to total in farms being 64.2. Of the total number of farms in 1870, 4,030 contained from 3 to 10 acres, 7,946 from 10 to 20, 18,099 from 20 to 50, 11,073 from 50 to 100, 5,039 from 100 to 500, 123 from 500 to 1,000, and 2 over 1,000. The cash value of farms was $27,847,429; of farming implements and machinery, $6,721-120; total amount of wages paid during the year, including the value of board, $4,459-201; total (estimated) value of all farm productions, including betterments and additions to stock, $38,446,400; orchard products, $15,818; produce of market gardens, $118,234; forest products, $111,528; home manufactures, $9,466; animals slaughtered or sold for slaughter, 20,420; all live stock, 290,118. The productions were 18,758,188 bushels of spring and 76,885 of winter wheat, 78,088 of rye, 4,743,117 of Indian corn, 10,678,261 of oats, 1,032,024 of barley, 52,458 of buckwheat, 44,601 of peas and beans, 1,943,063 of Irish and 1,596 of sweet potatoes, 3,045 of grass and 18,685 of flax seed, 665,663 tons of hay, 8,247 lbs. of tobacco, 401,185 of wool, 9,522,010 of butter, 263,977 of cheese, 222,063 of hops, 122,671 of flax, 210,407 of maple sugar, 92,506 of honey, 1,750 gallons of wine, 208,130 of milk sold, 38,735 of sorghum and 12,722 of maple molasses. Besides 9,667 horses and 54,862 neat cattle not on farms, there were 99,011 horses, 2,350 mules and asses, 121,467 milch cows, 43,176 working oxen, 145,736 other cattle, 182,945 sheep, and 148,473 swine. The agricultural statistics for 1872 were reported as follows by the state authorities:

In 1873 the number of acres under cultivation had increased to 2,332,672, of which 2,166,598 were sown with grain; number of farms, 58,373; there were 141,871 horses, 419,084 cattle, 4,005 mules and asses, 149,266 sheep, and 149,896 hogs.—As yet Minnesota does not hold a high rank as a manufacturing state, the people being more extensively engaged in agriculture. It has, however, a most important element for great industrial prosperity in the abundant water power afforded by its numerous streams. It has been estimated that about 100,000 horse power could be utilized during the day time throughout nearly the entire year, at the falls of St. Anthony; while the
St. Croix falls are only second to them in hydraulic power. The total number of manufacturing establishments reported by the census of 1870 was 2,270, having 246 steam engines of 7,085 horse power and 434 water wheels of 13,054 horse power, and employing 11,290 hands, of whom 10,892 were males above 16, 259 females above 15, and 139 youth. The capital invested amounted to $11,983,729; wages, $4,022,887; value of materials, $13,842,602; of products, $23,110,700. The most important industries are represented in the following statement:

The vast pine forests of Minnesota constitute an important source of wealth. It is estimated that about one third of the state is timbered land. On the head waters of the various tributaries of the extreme upper Mississippi and St. Croix rivers is an extensive "pine region," comprising an estimated area of 21,000 square miles. Vast pine forests are also found on the shore of Lake Superior, and on the Red river and its tributaries. The cutting and sawing of logs affords extensive employment for men and capital. In 1873, 164,743,150 ft. of logs were reported to have been sealed in the North Mississippi district, including 161,980,670 ft. at Minnesota, while 33,000,000 ft. were estimated to have been sawed but not sealed. The total number of feet sealed in the St. Croix district was 147,618,174; sawed and not sealed, 8,338,978; sawed and sealed, 94,229. In the Duluth district the number of feet sealed amounted to 6,147,988. In the St. Croix district the manufactured lumber was reported at 74,063,976 ft., besides 19,200,000 shingles and 19,477,850 lath. Minnesota has unusual commercial advantages, having within its limits three great navigable water systems, which are connected with the railroad system of the state, and afford continuous channels of communication with Hudson bay, the Atlantic ocean, and the gulf of Mexico. The Mississippi is navigable to St. Paul about 225 days in the year. The completion of the Northern Pacific railroad, which has its E. terminus at Duluth, on Lake Superior, and is now (1875) in operation to Bismarck in Dakota, 450 m., will give the state direct communication with the Pacific. This road, which joins the lake and the Red river water systems, is to be connected with the other railroads of Minnesota and the Mississippi river by three lines of railroad at the eastern, central, and western portions of the state. The Lake Superior and Mississippi railroad joins St. Paul, at the head of navigation on the Mississippi river, and Duluth, at the head of Lake Superior; while the former city will have direct connection with the Northern Pacific railroad by the two divisions of the St. Paul and Pacific, which are now in process of construction, one extending from St. Anthony to Brainerd, and the other from St. Cloud to St. Vincent, on the N. W. border of the state, a distance of 315 m., crossing the Northern Pacific at Glyndon, 13 m. E. of the Red river. This road is now in operation from St. Cloud to Melrose, 93 m. From St. Vincent it is to be continued to Fort Garry in the province of Manitoba, 61 m. from the Minnesota border. The state also has connection with the Union Pacific railroad by means of the St. Paul and Sioux City and Sioux City and St. Paul railroads. Furthermore, the completion of the contemplated improvements in the Fox and Wisconsin rivers will give to Minnesota a continuous water channel from the Mississippi river to Lake Michigan. The commercial importance of Minnesota will be seen from the fact that the entire trade of its great water systems, and much of that of its railroads, will here break bulk. The state comprises the United States customs district of Duluth and that of Minnesota, of which the port of entry is Pembina on the Red river, at the northern border of the state; and St. Paul is a port of delivery. The imports at Duluth during the year ending June 30, 1874, amounted to $12,129, and the domestic exports to $13,819. In the Minnesota district the imports were $182,054; domestic exports, $909,066; foreign exports, $2,521. The chief articles of export were oats, flour, and lumber. The number and tonnage of vessels that entered and cleared in the foreign trade, together with those registered, enrolled, and licensed, were as follows:

Of those enrolled in the Minnesota district, 54 were steamers and 39 unrigged vessels; and of those in the Duluth district, 6 of 1,282 tons were steamers. Besides the above, 259 vessels of 153,792 tons entered at Duluth in the coastwise trade, and 264 of 154,292
tons cleared. In 1873 5 steam vessels of 510 tons and 4 barges were built in the Minnesota district. Since 1857, when congress made to Minnesota a grant of six sections per mile of the public lands to aid in the construction of railroads, which was increased to ten sections per mile in 1865, not less than 12,200,000 acres of land, or more than one fourth of the entire area of the state, has been granted to railroad corporations, either by the general government or the state. These grants comprise 11,250,000 acres by congress and 1,950,000 by the state; and 5,515,007 acres have already been conveyed to the companies. The railroad companies in the state organized under special charters are required to pay to the state, in lieu of all other taxes, 1 per cent. of their gross earnings for the first three years, 2 per cent. during the next seven years, and 3 per cent. thereafter. Other railroad companies can acquire the same privileges by complying with the provisions of the law. The gross earnings of the companies subject to this law in 1873 were reported at $5,899,578, on which the tax amounted to $106,876. The gross earnings during the year ending Sept. 1, 1873, were $5,536,104, including $1,385,272 from passengers and $3,150,832 from freight. The total expenses of all the companies amounted to $4,410,885. A commissioner is appointed by the state, whose duty is to report to the legislature annually concerning the finances, business, and general condition of every railroad company in the state. Minnesota had 31 m. of railroad in 1868, 298 m. in 1866, and 1,092 in 1870. In 1874 there were 1,833 m. of main track and branches, exclusive of side track, &c. The railroads completed in the state, and their termini, in 1874, with the capital stock issued, the latter items being reported by the state commissioner for the year ending Sept. 1, 1874, are as follows:

<table>

There were 32 national banks in operation in Minnesota, Nov. 1, 1874, with a paid-in capital of $4,448,700; total amount of circulation issued, $4,465,000; amount outstanding at that date, $3,393,501, the latter being $77 per capita. The ratio of circulation to the wealth of the state was 1.5 per cent.; to bank capital, 76.3 per cent. There were five savings banks, with deposits aggregating $843,498. The total number of fire and marine insurance companies transacting business in the state in 1873 was 45, including 2 Minnesota and 36 other American and 7 foreign companies. The number of life insurance companies was 35, of which only one was organized under the laws of the state. The present constitution of Minnesota was adopted Oct. 13, 1857, and the government organized May 22, 1858. The qualifications for voters are, that they be males, 21 years of age, who have declared their intention of becoming citizens of the United States, and who have resided in the United States one year, and in the state four months next preceding. Indians and persons of mixed white and Indian blood, who have adopted the language, customs, and habits of civilization, are also allowed to vote in any district in which they have resided for the ten days next preceding. The legislature consists of 41 senators elected for two years and 106 representatives elected for one year. They must be qualified voters and residents in the state one year, and in their respective districts six months next before the election. The election is held on the Tuesday after the first Monday in November of each year, and the legislature meets on the Tuesday after the first Monday in January. Its sessions are limited to 60 days. The executive department consists of a governor (salary $8,000), lieutenant governor, secretary of state ($1,800), treasurer ($3,500), attorney general ($1,000), all
MINNESOTA

elected for two years, and an auditor ($2,500),
elected for three years. The judiciary com-
prises a supreme court consisting of a chief
and two associate justices (salary $3,000),
nine district courts, and a probate court in
each county, besides justices of the peace, who
have jurisdiction where the amount in dispute
does not exceed $100, and where the title to
real estate is not involved. All judges are
elected by the people, those of the supreme
and district courts for seven years and the
others for two years. The supreme court has
power to issue all remedial writs, and appoint
jurisdiction of judgments and orders of
the district courts. The latter have original
jurisdiction of all civil actions within their
respective districts when the sum in contro-
versy exceeds $100, all civil actions not within
the jurisdiction of justices of the peace, and
in equity; also appellate jurisdiction from
courts of probate and justices of the peace.
Besides the above named state officers, there
is a commissioner of railroads and a commis-
sioner of insurance. In 1872 a state board
of health was established, consisting of seven
physicians appointed by the governor from
different sections of the state, who are re-
quired to make sanitary investigations, and
collect and disseminate information concerning
the causes of disease and the effects of locali-
ties, occupations, &c., on the general health.
The public institutions are also made subject
to their sanitary inspection, and they are re-
quired to report annually to the legislature.
The state commissioner of statistics makes an
annual report to the legislature, embodying
the vital statistics of the state, agriculture,
property, taxation, &c. The constitution pro-
vides for the taking of a state census in 1865
and every ten years thereafter. The property,
real or personal, owned by a married woman
at the time of her marriage, continues to be
her separate property. During marriage she
may use and enjoy property and the earnings
of her industry free from the husband's con-
troul and from liability for his debts. She may
contract, and sue and be sued, as if she were
single, the husband not being liable for her
debts or contracts either before or during
coverture, except for necessary furnished to the
wife after marriage. In sales of real estate by
a married woman, however, the husband must
join in the conveyance, unless he has deserted
her for one year or she has cause of divorce
against him. The causes of divorce are adul-
tony, impotence, cruel and inhuman treatment,
sentence to imprisonment in the state prison,
willful desertion for three years, habitual drunk-
eness for a year, and cruelty. A married
woman may make a will without the consent of
her husband. A homestead comprising not
more than 80 acres of land in the country
with the buildings, or one lot with the build-
thereon in any town, city, or village, is
exempt from execution. The legal rate of in-
terest is 7 per cent. in the absence of agree-
ment; but any rate not exceeding 12 per cent.,
if agreed upon, will be valid. Registry of
births and deaths is required to be made by
the clerk of every city and town. Minnesota
is represented in congress by three represen-
tatives and two senators, and has therein
five votes in the electoral college. —The ac-
nowledged bonded debt of the state on Jan.
1, 1875, amounted to $480,000, which has been
contracted since 1867 for the erection of build-
ings for state institutions. (For an account of
the disputed indebtedness of the state see p.
611.) During the year ending Dec. 1, 1874,
the entire revenue of the state amounted to
$1,112,812, and the expenditures to $1,148,150.
The chief items of the receipts and disburse-
ments are represented in the following state-
ment:

RECEIPTS.

The total equalized valuation of taxable prop-
erty was $39,264,740 in 1861, $46,184,063
in 1865, $67,133,673 in 1870, $112,035,561
in 1873, and $217,427,211 in 1874. The great
increase of the last year is due largely to a new
tax law requiring property to be assessed at its
cash value. The total for 1874 includes 1,741,404
acres of land, exclusive of town and
city lots, valued with buildings at $113,410,-
620; town and city real estate, $85,994,793;
personal property, $45,021,798. Besides this,
90,533 persons had each $100 of property ex-
cept, or $9,053,300. The total taxes levied on
this equalized valuation amounted to $4,102,-
835, including $507,360 for state purposes,
$1,331,772 for common schools (a two-mill tax
yielding $433,193 and a special tax of $986,
In 1874 the state tax of five mills was levied, producing $561,459. All lands belonging to railroads are subject to taxation whenever sold or their sale is agreed upon. The number of acres of public lands surveyed up to Aug. 1, 1874, was 94,650,751, of which 10,900,756 had not yet been disposed of. The land not yet surveyed is in the northern part of the state.

The hospital for the insane at St. Peter will accommodate when completed 450 patients. The whole number under treatment in 1874 was 497, of whom 219 were women; number at the close of the year, 381; daily average, 341. Of those discharged during the year, 56 were recovered, 33 improved, and 4 unimproved; there were 24 deaths. The current expenses amounted to $35,017. The institution for the education of the deaf and dumb and the blind, opened in 1863, is beautifully situated at Faribault, and is free to all deaf and dumb and blind persons in the state between the ages of 10 and 25 years. In 1874 104 deaf and dumb and 22 blind students were in attendance, and there were reported in the state 71 persons of the former and 18 of the latter class who were not in any institution. Seven teachers are employed in the deaf-mute and three in the blind department. The complete course of study embraces seven years, and comprises, besides the usual subjects, instruction in industrial branches. Articulation and lip reading are taught to about 10 per cent. of the deaf mute. The expenses for 1874 amounted to $30,818. The soldiers' orphans' home, at Winona, at the close of 1873 had 65 pupils, of whom 38 were girls. The total expenditures in that year amounted to $17,451. Unlike institutions of this class in other states, except that in Pennsylvania, the home is a private incorporated association, having an agreement with the state for the support upon specified conditions of soldiers' orphans who are destitute. Only those between the ages of 4 and 16 years are admitted, and they are discharged at the age of 18 or younger. There is no school connected with the institution, but the inmates receive instruction in the state normal school. The state prison at Stillwater, and will have when completed a capacity for 500 convicts. United States military and civil convicts are confined here. In 1874 the average number of prisoners was 112, and the number remaining at the close of the year 134. The entire earnings of the prison amounted to $19,261, including $11,728 for convict labor and $6,499 for boarding United States military convicts. The cost of the prison after deducting the earnings was $17,618, or $158.27 for each convict. The labor of the prisoners is let out by contract. The reform school at St. Paul, opened in 1868, is intended for incorrigible and criminal boys and girls under the age of 16 years. At the beginning of 1874 there were in the institution 107 boys and 15 girls, all of whom were receiving instruction in the ordinary branches and industrial pursuits. Provision has been made for the establishment of an asylum for inebriates.—The permanent school fund is derived from the proceeds of the school lands, which comprise every 16th and 36th section, constituting one eighteenth of the entire public domain. It is estimated that these lands will amount to 2,900,000 acres. At the beginning of 1875, 450,357 acres had been sold, from which and the sales of timber a productive fund of $3,030,127 had been realized. The income of this fund amounted to $189,826 in 1874, which was distributed among the counties in proportion to the school population. The total distribution ($192,264) was based on the school population of 1873, 186,065, making the per capita appropriation 7 cents. The principal of this fund is protected by the constitution against diminution; and it is estimated that when the remainder of the school lands are sold the permanent school fund will exceed $15,000,000. The state superintendent of education is appointed by the governor, with the consent of the senate, for two years, and receives an annual salary of $2,500. County superintendents are appointed by the county commissioners. The most important statistics for the year ending Sept. 30, 1874, are given in the following statement:

| Number of persons between 5 and 21 years old | 210,154 |
| 15 and 21 | 57,550 |
| " attending school | 129,902 |
| " of school districts | 2,266 |
| " reporting | 2,114 |
| Number of winter schools | 2,769 |
| Average length in months | 9.56 |
| Total attendance | 8,864 |
| " Average | 71,822 |
| Number of summer schools | 2,718 |
| Average length in months | 3.71 |
| Total attendance | 8,751 |
| " Average | 10,048 |
| Number of teachers in all schools (male 3,645) | 5,562 |
| Average monthly wages of teachers | 301.86 |
| " male | 346.42 |
| " female | 229.91 |
| Number of schools | 2,758 |
| Value | $2,286,900 |
| Amount received from school fund, including 2-mill tax, fines, &c. | $392,708 |
| Amount apportioned from permanent school fund | 192,264 |
| " received from taxes voted by districts | 2,800,001 |
| " expended for school purposes, total | 1,189,643 |
| " for teachers' wages | 475,046 |
| " for school houses | 825,001 |

According to the federal census of 1870, the total number of educational institutions in Minnesota was 2,479, having 2,886 teachers, of whom 1,907 were females, and 107,264 pupils. The total income of all was $1,011,769, of which $2,000 was from endowment, $803,101 from taxation and public funds, and $106,668 from tuition and other sources. There were 2,424 public schools with 2,735 teachers and 103,408 pupils, 4 colleges with 31 teachers and 524 students, 3 academies having 10 teachers and 153 pupils, and 28 private schools with 29 teachers.
and 959 pupils. In 1874, 487 pupils were instructed in academies, 582 in colleges, and 2,980 in private schools, making with those in the common and normal schools a total of 133,584. Minnesota has three state normal schools: at Winona, opened in 1860; Mankato, 1868; and St. Cloud, 1869. The number of instructors and pupils in these during the year ending Nov. 30, 1874, together with the annual appropriation made by the legislature, was as follows:

For the further training of teachers, the superintendent of public instruction is required to hold annually in the thinly settled counties as many state teachers' institutes as practicable, each to continue in session at least one week. In 1874 six training schools of four weeks each and five institutes of one week each were held in 11 counties, and were attended by 1,024 teachers. The expense, $2,710, was borne by the state. These institutes are regarded as an important feature of the public school system. Applicants for position as teachers, if not graduates of a normal school, are required to obtain a graded certificate, which is granted on examination by county superintendents.—The state university is described in the article MINNESOTA, UNIVERSITY OF. Carleton college (Congregational), at Northfield, was organized in 1856, and has an English preparatory and a collegiate course, which are open to students of both sexes. In 1873-4 it had 10 instructors and 171 pupils, of whom 7 were in the college and 165 in the preparatory department; 64 were females. St. John's college is an important Roman Catholic school at St. Joseph's, organized in 1856, and having in 1873-4 22 instructors and 26 students in the ecclesiastical and 97 in the classical and commercial course. Macalester college (Presbyterian) at Minneapolis was opened in 1874. Besides the theological department of St. John’s college, instruction in theology is afforded by Augsburg seminary (Evangelical Lutheran) at Minneapolis, which was founded in 1859, and in 1873 had 5 instructors and 63 students. The only institution exclusively for the higher education of women which reported to the United States bureau of education in 1873 was St. Mary’s Hall at Faribault (Protestant Episcopal), which in 1873-4 had 14 instructors and 114 pupils. There are, however, seminaries for the secondary instruction of girls at Hastings, Minneapolis, and St. Paul. There are also several well conducted academies open to boys and girls in St. Paul, Red Wing, Caledonia, and other places. There are from 15 to 20 excellent high schools in the state, in which students may be prepared to enter the state university. Several private schools afford instruction in the Norwegian and Swedish languages. There are business colleges in St. Paul and Minneapolis.—According to the census of 1870, there were in the state 26,763 libraries, with an aggregate of 2,174,744 volumes; 23,701 with 1,596,113 volumes were private, and 3,062 with 578,631 volumes were other than private, including the state library of 10,000 volumes, and 23 circulating libraries containing 16,601 volumes. Besides the state library, the most important ones are that of the university of Minnesota, which contains about 10,000 volumes; St. Paul library, 6,000; the Minneapolis Athenæum, 4,000; and that of the state historical society at St. Paul, which has 5,643 bound and 8,730 unbound volumes. The whole number of newspapers and periodicals was 95, having an aggregate circulation of 110,778 copies, and issuing annually 9,543,656. There were 6 daily, with a circulation of 14,800; 5 tri-weekly, 4,200; 79 weekly, 79,978; and 5 monthly, 11,800. In 1874 the number reported was 128, including 7 daily, 4 tri-weekly, 112 weekly, and 5 monthly. The total number of religious organizations in 1870 was 677, having 592 editions, with 158,066 sittings and property valued at $3,491,750. The denominations were represented as follows:

<table>

—Though of recent settlement, Minnesota has long been the seat of a considerable traffic with the Indians, and of missionary enterprise. As early as 1808 Hennepin and La Salle penetrated these wilds, followed by La Hontan and Le Sueur, and in the last century by Carver; and within the present century this region has been thoroughly explored by Pike, Long, Keating, Nicollet, Schoolcraft, Owen, and others. But it was not until 1812 that the United States had any authority within the limits of Minnesota. In 1816 a law was passed excluding foreigners from the Indian trade; and the military post at Fort Snelling was established.
in 1819. In 1837 a small tract of country be-
tween the St. Croix and Mississippi was ceded by the
Indians to the United States, and lumbering
operations commenced upon the St. Croix.
The territory of Minnesota was established by
an act of congress passed March 3, 1849, and
the government was organized in June. It
embraced nearly twice the area of the present
state, its western limits extending to the Mis-
souri and White Earth rivers. Up to this pe-
riod the country was occupied almost entirely
by Indians; but a small civilized population of
whites and half-breeds had grown up around
the trading posts and mission stations, amount-
ing in 1849 to 4,857. In 1851 the Sioux ceded
to the United States all their lands in the ter-
ritory W. of the Mississippi to the Big Sioux
river. The population increased so rapidly
after this, that in 1857 application was made
for admission into the Union. In the con-
vention assembled to frame a state constitu-
tion, a dispute arose among the delegates,
which resulted in the secession of a portion
and the formation of another convention. The
two conventions, known as the republican and
the democratic, held sessions at the same time
in St. Paul. A compromise was effected, and
the same constitution was signed by the dele-
gates of both conventions and submitted sepa-
rately to the people by each convention, with
the names only of its officers and delegates.
It was ratified by an overwhelming majority.
According to the census ordered in the ena-
bling act, and dated Sept. 21, 1857, the terri-
tory contained 150,092 inhabitants. The act
authorizing the formation of a state govern-
ment passed congress Feb. 26, 1857, and the
state was admitted into the Union May 11,
1858, with the boundaries above described.
That portion of the state lying on the E. side
of the Mississippi originally belonged to the
country termed the "Territory Northwest of
the Ohio," and had the ordinance of 1787 been
fully complied with would have been included
in the 5th state (Wisconsin) formed from that
region. This section comprises an area of 22,336
square miles. The part of the country lying
W. of the Mississippi, and embracing more
than two thirds of its area, was originally a
portion of Louisiana, and came into the pos-
session of the United States in 1803; and be-
fore it was included in Minnesota it had been
a part of the territory of Missouri, and subse-
quently of Iowa. There are bonds amounting
to $2,275,000 outstanding against the state,
the validity of which has been disputed. These
bonds were issued in 1858 and lent to railroad
companies, upon the authority of an amend-
ment to the constitution made in that year.
Soon after receiving them the companies, as
is alleged, failed to comply with the condi-
tions upon which the bonds were granted, and
payment was refused by the state. In 1860
another amendment to the constitution was
adopted "expunging" the amendment of 1858,
and providing that "no law levying a tax or
making other provisions for the payment of
principal or interest of the bonds denominated
Minnesota state railroad bonds shall take effect
or be in force until such law shall have been
submitted to a vote of the people of the state
and adopted by a majority of the electors of
the state voting upon the same." Before this
amendment was adopted the mortgages held
by the state had been purchased and the mort-
gaged railroads bought by the government at
nominal prices. In May, 1871, a popular vote
was taken on a proposition for settlement by
arbitration of these claims, when 21,408 votes
were cast against and 9,293 in favor of the
proposition, the total vote being less than half
the average vote of the state. The total num-
er of men furnished by Minnesota to the army
and navy during the civil war was 25,034, or
19,675 reduced to a three years' standard.
MINNESOTA, or St. Peter's, a river of Min-
nesota, having its source in a series of lakes on
the Dakota border, between lat. 45° and 46°
N., and pursing a S. E. course for about 320
m., to its confluence with the Blue Earth; then
turning N. E. it flows in the division for
about 120 m., falling into the Mississippi at
Mendota. Its course is principally in the val-
ley lying between the Coteau du Grand Bois
and the Coteau des Prairies. For its whole
distance from Big Stone lake it has a fall of
only 220 ft. It is navigable for steamers about
40 m. to a point where at low water a ledge
of rocks obstructs further progress; but ordi-
narily small boats can ascend to Patterson's
rapids, 205 m. from its mouth.
MINNESOTA, University of, an institution of
learning in Minneapolis, Minn., beautifully sit-
uated on a bluff on the E. bank of the Missis-
ippi river, one mile below the falls of St. An-
thony. The college grounds comprise about
30 acres. The experimental farm of the agri-
cultural college is about half a mile below, near
the Bridal Veil falls. The buildings comprise
a main academic edifice, 180 by 90 ft. and four
stories high, and an agricultural college, 150
by 54 ft., two stories high, including a chemi-
cal laboratory and a plant house of glass.
The total cost of these buildings was $100,000,
appropriated by the state. The university had
a nominal existence, under a provision of
the state constitution, as early as 1857, but it
was not till 1867 that a preparatory depart-
ment was opened. In 1868 the university
was reorganized, and to the board of regents
was intrusted the income to be derived from
the state's share of the lands given in 1857 by
the general government for the endowment of
colleges of agriculture and the mechanic arts.
In September, 1869, the first faculty was or-
ganized, the president being William W. Fol-
well, M. A., who still retains that office (1875).
In 1870 the board of regents adopted a plan of
university organization in some respects novel.
The work of the first two years of the ordinary
college course was merged with the last two
years of the existing preparatory department
MINNETAREES into a department of elementary instruction, otherwise called the collegiate department. Having completed a four years' course in the collegiate department, the student then has his option to enter at once some one of the professional schools, or to proceed with higher academic studies in the college of science, literature, and the arts. The collegiate department is merely a temporary attachment, it being part of the plan of organization to drop off its studies as fast as the schools can assume them. The lowest class is to be discontinued at the close of the year 1874—5. In 1875 the following colleges or departments, with the courses and degrees named, had been opened: 1. The collegiate department, known in the organic law as the department of elementary instruction, having three courses of study: classical, scientific, and modern. The faculty have authority to permit students to select studies from the various courses, but the programme is arranged with reference to the wants of the regular students. No degrees are conferred in this secondary department. 2. The college of science, literature, and the arts, which presents a similar variety of courses, but with a large increase of options. The degrees of B. A., B. S., and B. L. are conferred upon students who complete the respective courses and pass the examinations. 3. The college of agriculture, offering an advanced or university course, based on the preparation of the collegiate department and leading to the degree of B. Agr.; and an elementary course coinciding in the main with the scientific course of the collegiate department. 4. The college of mechanic arts, with courses in civil engineering, mechanical engineering, and architecture, leading to appropriate baccalaureate degrees. Post-graduate courses are to be arranged, leading to the master's and other higher degrees. In 1870 the announcement was made, "No degrees except upon examinations." The government of the university is vested in a board of ten regents, of which the governor, the superintendent of public instruction, and the president of the university are members ex officio, the remaining seven being appointed by the governor with the consent of the senate, and holding their offices for three years. No applicant is admitted to the university without examination, and the only tests of progress are the examinations. The university maintains no dormitories. Tuition is free in all departments. Both sexes are admitted. The number of students in 1874—5 was 285. The faculty numbered 14 resident officers and one non-resident. The library contained about 10,000 volumes. By a law of 1872 the geological and natural history surveys of the state were intrusted to the university. Considerable collections have been made by the professors engaged in the surveys. The financial basis of the university consists in the following grants of public lands: 1, 46,000 acres to the territorial university; 2, 46,000 acres to the state university; 3, 120,000 acres, being the so-called agricultural grant of 1862, for the benefit of colleges of agriculture and the mechanic arts; 4, 12 sections of salt lands for the expenses of the geological survey. In 1874 the state legislature made an annual appropriation of $19,000. The total annual income at that time amounted to $50,000, the institution still retaining about 185,000 acres of public lands, all within the state.

MINNETAREES, a tribe of Indians on the upper Missouri, who are called by the Canadians Gros Ventres of the Missouri, but by themselves Hidatsa. They were originally part of the Crow nation, but separated from it after a quarrel. They came to the Mandans in a state of destitution, nearly all the men having fallen in battle. The Mandans did not allow them to enter their village, but permitted them to settle near. They gradually recovered, and adopted many Mandan customs and ideas, but have retained their own language. Lewis and Clarke in 1804 found the tribe in two villages on opposite sides of Knife river near the Missouri. They numbered 2,500, and traded with the great English fur companies, defending themselves against the Sioux, and making war on the Shoshones and Flatheads. The United States made a treaty with them at the lower Mandan village, July 30, 1825. They have never been hostile to the whites. When the smallpox swept away most of the Mandans in 1838, the Minnetarees were reduced to about 500. In 1842 they numbered about 300 males and 800 females, in 75 lodges, their village lying about 8 m. above the Mandans; but in 1845, under the constant attacks of the Sioux, they united with a part of the Mandans in a palisaded village at their present site, where Fort Berthold was erected the same year. They were then estimated at 760 souls. Though a treaty was made at Laramie in September, 1851, to which they adhered, the Sioux continued their hostilities, and in 1862 killed Four Bears, their head chief, a man of remarkable ability. During the civil war no arms or ammunition was issued to these tribes, while the Sioux procured supplies from the British territory, and in spite of all treaty obligations killed and plundered these unoffending Indians, who were unable to go on their usual hunts. They ceded some of their lands in 1864. In 1870 peace was again made with the Sioux and arms were furnished to the Minnetarees; at the same time a reservation in Dakota and Montana was set apart for them, but in 1873 they were still at Fort Berthold. They are reduced to 626, the Mandans, and since 1863 the Rickarees occupying part of the village. The Minnetarees are tall, well made, and light in color. They dwell chiefly in peculiar earth-covered lodges like those of the Mandans, 30 to 50 ft. in diameter. Every winter they go many hundred miles up the Missouri and Yellowstone valleys to hunt. Their religious ideas and rites are similar to those of the Man-
minnows. No attempt has been made to civilize or Christianize them beyond occasional visits of Roman Catholic missionaries. An account of the tribe and its language is given in Washington Matthews's "Grammar and Dictionary of the Hidatsa" (New York, 1873); see also "Hidatsa (Minnetaree)-English Dictionary" (New York, 1874).

**MINNOW**, the common name of many small cyprinodont fishes, of the genera *Fundulus* (Lacép.) and *Hydronyx* (Lacép.). In *Fundulus* the upper surface of the head is flattened; fine card-like teeth upon the jaws, and short ones on the posterior part of the hyoid arch, with opposite velvet-like patches on the roof of the mouth; no teeth on palate or vomer; branchial rays five; dorsal opposite the anal, and caudal rounded; upper surface and sides of head covered with scales. The common minnow, or "cobbler" of the young smelt fishes (*F. piceulentus*, Cuv. and Val.), is from 1 to 5 in. long; the females are of a uniform brown color; the males with lighter intervals on the sides arranged like transverse bands, the dorsal and anal with black dots, and anal slightly emarginated posteriorly, mouth protractile, and upward when closed. It abounds about the salt marshes of the northern and middle states, and is caught in large numbers in hand nets, as bait for other fish, particularly

**MINOW (Fundulus piceulentus).**

smelts.—The yellow-bellied minnow (*Hydronyx flavula*, Storer) is from 1 to 5 in. long; the female is yellowish above, lighter on the sides, and white beneath, with from one to five longitudinal interrupted black bands extending along the sides from the gill covers to near the tail, where there are three or more indistinct transverse bands. In this genus the head is more flattened, and the branchial rays are six. It is found in southern New England and New York.—The cyprinoid black-nosed dace (*Argyrostomus atronuca*, Heck.) is sometimes called brook minnow. The British minnow or minnow (*Leuciscus phoxinus*, Cuv.) rarely exceeds 3 in. in length; it is generally found in the same streams with trout, swimming in shoals.

**MINO BIRD (Gracuula religiosa),** a conrostral bird of the starling family and subfamily *Graculiinae*. In this genus the bill is as long as the head, broad at the base and strong, with the culmen curved, sides compressed and nearly straight, and tip slightly notched; nostrils partially covered by the frontal plumes; wings long, with the first quill rudimental, and the second shorter than the third and fourth, which are longest; tail short and nearly even; tarsi shorter than the middle toe, stout, and covered with strong scales; toes long, the outer the longest, and the hind one very long and strong; claws curved and robust; some parts of the head are naked or carunculated. This species, the best known of the genus, is about 104 in. long, of which the tail is 3, and the expanse of wings 19 in.; the body is round and plump; the color is velvet black, with green, blue, and purple reflections; on the wings is a white speculum; the bill, feet, and caruncles behind the eyes, yellow. It is found in Java, Sumatra, and other islands of the East Indian archipelago, inhabiting the jungles, where it is seen in pairs or small parties in the tops of lofty trees, searching for fruits, berries, and insects. It is easily domesticated, and becomes very familiar; it soon learns to whistle, sing, and talk, imitating the human voice, according to Latham, more nearly than any other bird; it is frequently kept as a cago bird in the East Indies, and sometimes in Europe and in this country, where as much as $100 has been paid for a single bird. Another species, with similar habits, is the musical grackle (*G. musica*, Temm.), found also in the East Indies.

**MINORCA** (Span. *Menorca*; anc. *Balearis Minor*), the second in size of the Balearic islands, lying 24 m. E. N. E. of Majorca, about 125 m. S. E. of Barcelona, between lat. 39° 47' and 40° 5' N., and lon. 5° 50' and 4° 28' E.; greatest length 53 m., greatest breadth 18 m.; area, 283 sq. m.; pop. about 45,000. The coast is indented on every side with small bays, several of which form excellent harbors. The surface is rugged, and rises gradually toward the centre, where it attains in Monte Toro an elevation of nearly 5,000 ft. The climate is very hot in summer and cold in winter, and the soil is rather sterile. Iron, lead, copper, and marble are found. The inhabitants are almost entirely engaged in agriculture, fishing, and commerce. Minorca is of great commercial importance in the Mediterranean trade, and the capital, Port Mahon, has an excellent harbor. During the greater part of the 18th century Minorca belonged to the British, who ceded it to Spain at the peace of Amiens (1802). (See *BALEARIC ISLANDS*.)
MINORITES. See Franciscans.

MINOS, in Greek mythology and legends, a Cretan hero and lawgiver. According to Homer, he was the son of Jupiter by Europa, brother of Rhadamanthus, and the father of Deucalion and Ariadne. The logographers make him also the brother of Sarpedon and husband of Pasiphaë. Some later writers distinguish two kings of the name, grandfather and grandson, but only one Minos was known to Homer, Hesiod, or the poets and historians to the time of Aristotle. To obtain possession of the throne of Crete, he affirmed that the gods granted him everything for which he prayed. He accordingly prayed that a bull might come forth from the sea, and promised to sacrifice it to Neptune. The bull appeared, and he obtained the kingdom; but, admiring the beauty of the animal, he sacrificed another in its place. Thereupon Neptune afflicted his wife Pasiphaë with a monstrous passion for the bull, for the gratification of which the inventor Deedalus contrived means, and she became the mother of Minotaur, a creature with the body of a man and the head of a bull, which was imprisoned by Minos in the Cretan labyrinth. The Cretans traced their legal and political institutions to Minos, it being said to have been instructed in the art of law-giving by Jupiter himself; and Lycurgus was believed to have followed his legislation as a model. After death he was constituted one of the judges in Hades. Later accounts represent him as an unjust and cruel tyrant. He is said to have acquired great maritime power, conquered the /Egean islands, made war upon Athens, and compelled the Athenians to send to Crete periodically a tribute of seven youths and seven maidens to be devoured by the Minotaur. These with the aid of Ariadne at length slew the monster and abolished the tribute. In a subsequent attempt to conquer Sicily Minos failed and was killed.

MINOT. George Richards, an American jurist, born in Boston, Dec. 28, 1758, died Jan. 2, 1802. He graduated at Harvard college in 1778, practised law in Boston, became clerk of the Massachusetts house of representatives in 1781, secretary of the convention which ratified the federal constitution, judge of probate for the county of Suffolk in 1792, and judge of the municipal court of Boston. He published an oration on the Boston massacre; a "History of Shay's Rebellion" (8vo, 1788); "Enquiry on Washington" (1800); and a "History of Massachusetts Bay" from 1748 to 1765 (2 vols., 1798-1803), in continuation of Gov. Hutchinson's.

MINIS. See MISSES.

MINSK. I. A S. W. government of European Russia, bordering on Vitebsk, Mohilier, Tchermezov, Kieve, Volhynia, Grodno, and Vilna; area, 35,295 sq. m.; pop. in 1867, 1,135,589. The territory of Minsk is a vast plain, over which are scattered a few hills of moderate elevation. In the north and east are large forests, and toward the south and southwest extensive marshes. The principal rivers are the Dnieper (which partly bounds it on the east), Niemen, Priepet, and Beresina. The climate is very severe in winter, but pleasant in summer. Agriculture is the principal occupation. The chief manufactures are fine cloths, linen, and sugar. The principal exports are timber, salt, and grain, which are brought by the rivers to the ports of the Baltic and Black seas. The population is composed chiefly of Lithuanians, Poles, Russians, and Jews. Five sevenths of them adhere to the Greek church. The inhabitants of the southern marshy portion are subject to the disease called plica Polonies. Among the more important towns are Pinsk and Slutzk. Minsk is divided into 10 circles, and was formerly a part of the Lithuanian provinces of Poland. II. A city, capital of the government, on the Svislotch, 110 m. S. E. of Wilna; pop. in 1867, 36,277, a large part of whom are Jews. It is the seat of a Greek archbishop and a Roman Catholic bishop. It has a fine cathedral, a number of other churches, a gymnasium, and a theatre. An important trade in grain is carried on. The names of Minsk were subjected to persecution by the emperor Nicholas in 1840.

MINSTRELS (Lat. minstrellus, diminutive of minister; Fr. meneestrel), a class of men in the middle ages who amused their patrons by the arts of poetry and music, singing to the harp their own verses, or the popular ballads and metrical histories of the time. They sometimes accompanied their music with mimicry and action, so that they were often called mimi and histriones. The name minstrel is of Norman origin, and they were successors of the skalds and bards of the north. The office became degraded, the minstrel on the continent being commonly classed with the dancer and mimic; while the Latin names mimi, scena, histriones, and joculatorae are grouped together. In England Edward II., Henry V., and Henry VI. showed great regard for minstrels; but the reign of Richard Coeur de Lion was their golden age. When Henry V. set out on his great expedition to France, 18 minstrels, with an allowance of 12d. a day each, accompanied him. But from the reign of Edward IV. their art seems to have declined. Toward the close of Elizabeth's reign a statute was enacted, by which wandering minstrels were punished along with rogues, tinkers, peddlers, vaga-bonds, and beggars.

MINT, the name of plants of the genus mentha (from Mintha, a nymph changed into this plant), of the order labiata, which is distinguished from related genera by an almost regular corolla and four fertile stamens; there are about 30 species, but few of which have any other than a botanical interest. Generally, when mint is spoken of, that which is also known as spearmint (M. cervisii) is understood, while the
common names of the other species have a descriptive prefix. Spearmint, common mint, garden mint, or usually simply mint, is a native of Europe, though found about moist ground and waste places in the United States, having strayed from gardens and fields where it has been cultivated. It is handsome, cleanly, of a deep green color, with an erect stem 1 to 2 ft. high, furnished with oblong-lanceolate, nearly sessile, acutely serrate leaves, and ending in slender, tapering spikes of pale purple flowers. The fresh leaves, chopped fine and mixed with sugar and vinegar, form the mint sauce much eaten with lamb, and bruised they are used for compounding various beverages, especially mint julep. An oil, upon which the properties of the plant depend, is separated by distillation in the same manner as described for peppermint; from this is prepared an essence, by dissolving it in alcohol, and a water, by mixture with that liquid, both of which are used to cover the taste of other medicines.—Peppermint (M. piperita) is more sparingly naturalized than the preceding, from which it differs in its more interrupted spikes and petioled leaves; it has a more pungent and camphoraceous taste and similar stimulating properties. The plant is largely cultivated for the production of the oil of peppermint, a culture that was at one time exclusively confined, in this country, to Massachusetts, the western part of New York, and some counties in Ohio, but was later taken up by the farmers in southwestern Michigan, where some years ago the breadth of land devoted to this crop was between 2,000 and 3,000 acres. At one time St. Joseph’s county, Mich., was the headquarters for oil of peppermint, but recently the makers in Wayne county, N. Y., have by attention to the quality of the product established a reputation which has led to increased production, and this county now produces more in value if not in quantity than any other district. Those engaged in the business have met with variable success, as the oil has been the subject of the operations of speculators; at one time the whole production of the country was controlled by a single firm, which in order to diminish the supply contracted with many large growers to discontinue the cultivation for life years. Peppermint requires a warm, rich soil; the land is laid off in furrows 15 to 2 ft. apart, and sets, or parts of old plants, are planted thickly in the rows; the plants are kept free from weeds until they cover the soil; the harvest begins early in August and continues until October; the first crop of the field is the best, the second and third being much less; the fourth year the field is ploughed, and the crop springs up from the broken roots; the yield of the fifth year is about equal to that of the second, and after this the land is devoted to other uses. The first year’s crop is best, not only because the plants are young and vigorous, but the mint is then free from a weed which is apt to spring up later, and also yields a volatile oil, which is bitter and pungent, and deteriorates the product; this weed, called mare’s-tail, fireweed, and by several other names, is erecthites hieracifolius, a composite somewhat resembling lettuce in appearance. The mint is cut with a cradle having two fingers, and raked into cocks, where it remains 12 hours to wilt before it is distilled. The still is a wooden vat of heavy staves hooped with iron, 4 ft. deep and 6 ft. in diameter; the wilted mint is packed into this vat by treading it close with the feet until the vat is full, when the lid is fastened down steam-tight; a pipe enters the lower part of the vat to convey steam from a boiler, and another from the top of the vat connects with a worm, as in an ordinary still. The steam being let on, the oil from the mint is volatilized, and its vapor, mixed with steam, is condensed in the worm; the mixed oil and water are collected in a receiver, when they separate by their difference in specific gravity. The oil is packed in tin cans holding 20 lbs. each, and a large share of the product is exported. The chief consumption of the oil is for flavoring confectionery, and it also enters into the preparation of essences, cordials, and the like. Essence of peppermint, a popular emmenagogue, is a solution of the oil in alcohol, of a strength proportioned to the price. Peppermint water is prepared like other similar waters by first rubbing up the oil with carbonate of magnesia, slowly adding water, and filtering, a fluid dram of the oil to a pint of water; the use of the magnesia is to finely divide the oil and expose a large surface to the water, in which it is slightly soluble; any other inert powder will answer as well.—Corn mint (M. arrhena), which has the odor of decaying cheese, the round-leaved mint (M. rotundifolia), the water mint (M. aquatica), and the whorled mint (M. nativa), are other European species naturalized in some localities, but mostly rare.—Our only native species, the wild mint
(M. Canadensis), is a common plant in damp places from Kentucky northward; it has hairy stems and leaves, and flowers in axillary whorls; its taste and odor are like those of pennyroyal. A smooth form of this, which has been called M. borealis, has a pleasanter odor.

**MINT** (Ang.-Sax. mynet, from mynetian, to mark), a place where money is coined by a government. The early methods of coining money were exceedingly imperfect. The metal, brought to the required standard of fineness, was melted and cast into small bars, which were reduced to thin plates under the hammer. Square pieces cut from these plates were rounded at the forge, and then by means of rude dies, one fixed like an anvil, and the other held in the hand and struck with a mallet, the round lump of metal was flattened and coined at the same time. The coins were apt to be irregular in weight and form, and not entirely round, and were liable to be clipped. It was not until the middle of the 17th century that the forge and the hammer gave way permanently in France and England to the mill and screw.—In Britain, in the 1st century of the Christian era, Canobelin, king of the countries lying between the Thames and the Nene, established his mint at Camulodunum (Colchester), and there coined money of gold, silver, and brass. In early Saxon and Norman times establishments under the crown for the coinage of money existed in almost every important town. In the reign of Ethelred II. (978–1016) there were 38 mints, and in that of Canute (1016–1035) 37. In those days communication between the different parts of the realm was at once difficult and dangerous, and it therefore became important to have the sources for the supply of money for the various districts within those districts. After the Norman conquest the number of these mints was gradually reduced, so that in the reign of Henry VI. (1422–1460) the only ones in England were at Bristol, Canterbury, Coventry, Durham, London, Norwich, Oxford, and York; in the reign of Henry VII. they were only at Canterbury, Durham, York, and London; and it is supposed that in the time of Elizabeth all coins were made at the mint in London. But when, in the reign of William III., a very extensive coinage of silver took place, several local establishments outside of London were employed. Athelstan appears to have been the first monarch who established any regulations for the government of the mints of the kingdom. His law, proclaimed about 928, provided that but one sort of coin should pass current, and granted to various towns each a number of coiners or moneymen, and to boroughs of inferior size each one moneymoon. All provincial mints received their dies from the mint of London. The moneymen coined money and distributed it, received that which was clipped or worn, and bought bullion, the right to do which the monarch claimed as his own exclusive privilege. The moneymen seem in those early times to have had almost entire control of the mints. Their names were stamped upon the coins, as a guarantee of their genuineness, as early as the time of Egbert, king of Kent, about the middle of the 7th century. Edward II., in the 18th year of his reign, made a considerable change in the organization of the mint. He appointed a master, warden, comptroller, king's and master's assay master, and king's clerk; and under this constitution it continued substantially till 1815. From an early period in English history, the clergy of the superior ranks shared with the king the prerogative of coinage; the bishops of Durham had for centuries enjoyed the privilege of coining sterlings and penceys, and about 1473 the then bishop, who did not consider himself authorized to coin halfpence without obtaining the king's permission, applied for it, and it was granted. During the civil war in the reign of Stephen, when the country was in great disorder, almost every baron usurped the prerogative of coinage and issuing money, which consequently became very much debased. In 1156 Henry II. issued a new coinage, and prohibited the use of any other money. Hammering money ceased current in England until the reign of William III., although the system of milling had been introduced from France in 1562, during the reign of Queen Elizabeth; but it remained in practice only ten years, when the old system was again resorted to on account of its greater cheapness. The invention of the mill for coinage is attributed to Antoine Brucher, a French engraver, who first tried it in Paris, in the palace of Henry II., for coinage counters. It was continued in use till 1585, in the reign of Henry III., when it was abandoned on account of its expense. In 1631 a commission was appointed in England to examine into the process of coinage milled money proposed by Nicholas Bryitt of Lorraine; but nevertheless all coins continued to be hammered till 1662 or 1663, when the milling process was finally and permanently adopted; and Bryitt seems to have been appointed chief engraver to the mint, and to have put the system into practice. It had already been adopted in France in 1645.—

The early milling operations employed four different machines: the rolling mill, for laminating the metals to plates of the proper thickness; the punching-out machine (fig. 1), for cutting out the blanks or planchetts; the machine for milling the edges (fig. 2); and the coining press (fig. 3), which stamped the impression on both sides at once. The hammer money which was called in by William III. had been so much clipped and filed as to have lost about half its value.
Such confidence was felt in the new money by reason of its being milled on the edge, that it was deemed almost if not quite impossible to abstract any portion of the metal from it. But it was soon found that this money could with facility be subjected to the “sweating” process, in which a portion was dissolved by acids from the surfaces of both gold and silver coin

![Machine for Milling Edges](image)

![Coining Press](image)

without being perceptible to the eye. In 1810 the mint, which from an early age had existed in the tower of London, was removed to a new building on Tower hill, with new and improved machinery and engines. In 1815 it was placed under a new system of organization, which lasted till 1851, when it was again reorganized.—Seigniorage, the deduction made from the bullion to cover expenses and to pay the sovereign for his prerogative, at one time formed a considerable part of the revenues of the crown; and it was not always fixed by law or uniform in amount, but was very often subject to the caprice of the monarch. In the time of Henry III. it was 6d. in the pound, and Henry VIII. had 50s. for every pound weight of gold coined. Charles II. relinquished it entirely, but in the reign of George III. it was again imposed upon the silver coinage, and when the market price of silver is 5s. an ounce it is equivalent to 10 per cent. apparent profit; but as the government is obliged to keep up at its own cost the renewal of the silver coin, the wear and tear of which is considerable, the real profit is trifling. While the English mint is said to be one of the most economical and efficient manufacturing establishments in Great Britain, the loss by the abandonment of the seigniorage is 3d. on each sovereign. This free coinage of Charles II., says a recent English writer, “was made partly as a concession to the goldsmiths, and partly under the impression that with a free mint we should attract all the gold of Goleconda and Peru to our coffers. Till then it had been the custom of the English government, as it is still the custom of every government but our own, and that of an own government in India and Australia, to levy a seigniorage of 1 per cent. or thereabouts upon the work of the mint.” This seigniorage was relinquished by Charles II. in consideration of the house of commons presenting him with the customs duties.—Mints and Assay Offices in the United States. Under the coinage act of 1873, which reorganized this branch of the public service, the following mints and assay offices are in operation: the mints of Philadelphia, Pa.; San Francisco, Cal.; Carson City, Nev.; and Denver, Col.; and the assay offices of New York, Charlotte, N. C., and Boise City, Idaho. The mint, by the act of April 2, 1792, was established for the purpose of a national coinage at Philadelphia. The machinery, as well as the metal first used, was imported. Steam power was first introduced in 1816. The first money coined by authority of the United States was copper cents in 1793. In 1794 silver dollars were coined, and in 1795 gold eagles. Branch mints were established in 1835 at New Orleans, La., Charlotte, N. C., and Dahlonega, Ga.; in 1854 at San Francisco, Cal.; and in 1870 at Carson City, Nev. Assay offices were established at New York in 1854, at Denver, Col., in 1864, and at Boise City, Idaho, in 1872. These various establishments were branches of the mint at Philadelphia, and under this organization the coinage was conducted till April 1, 1873, when the new law became operative. This law established the mint and assay offices as a bureau of the treasury department, placed the several institutions upon substantially an equal basis, and brought them all under the general supervision of the chief officer of the bureau. Under this act the officer previously called director of the mint took the title and assumed the duties of the superintendent of the mint at Philadelphia. The bureau of the mint of the United States is in charge of the director of the mint, who is under the general direction of the secretary of the treasury, and is appointed by the president, by and with the advice and consent of the senate, for five years, unless sooner removed by the president for rea-
MINT

sons to be communicated by him to the senate. The officers of each mint are a superintendent, an assayer, a melter and refiner, and a coiner, and for the mint of Philadelphia an engraver. The following are the usual forms in which gold bullion is received: lumps, grains, and dust in their native state; amalgam with the quicksilver burned off; foreign coin, United States coin issued before 1834, and United States defaced coin issued since; jewelry, dentists' plate, bars, rings, &c. The following are the usual forms in which silver bullion is received: foreign coin, United States coin issued before 1833, and United States whole dollars and defaced coin issued since; plate, bars, rings, &c.; native lumps and grains in their native state; and, as an accommodation to the holders, the coppery silver of Lake Superior, but it must contain at least one fourth silver. Deposits of bullion, not less than $100 in value, are receivable by the superintendent, who causes it to be weighed in the presence of the depositor, and gives him a receipt therefor expressing the weight in troy ounces. Each deposit is kept separate during the process of melting and assaying, and until its precise value is determined. This is generally accomplished in three days, when, on presentation of the original receipt, the net proceeds are paid to the depositor or his order. The charge for converting standard gold bullion into coin is one fifth of 1 per cent.; and the charges for converting standard silver into trade dollars, for melting, refining, toughening, &c., are fixed from time to time by the director so as to equal but not to exceed the actual average cost. Deposits of gold are paid in gold, and if the deposit contains the value of over one dollar of silver clear of parting charges, the value of such silver is paid in silver coin. The charges for refining and separating silver from gold vary from one cent to six cents an ounce; for coinage of gold, one half of 1 per cent.; and for making fine gold bars, six cents per $100 if the deposit contains silver, and if not, five cents an ounce. Deposits of silver are paid in silver. If the silver deposit contains the value of over one dollar in gold, clear of parting charges, the value of such gold is estimated and paid in gold coin. The charges for refining and separating gold from silver vary from one third of one cent to six cents an ounce; for coinage into trade dollars they are 50 cents per 100 pieces; for making fine silver bars, one half cent an ounce on the fine silver. Silver bullion is purchased at 118 cents an ounce (standard fineness nine tenths pure silver), and paid for in silver coin of less denomination than the dollar. Each deposit of gold or silver is melted and cast into bars, being thus brought into a homogeneous state, so that an assay piece taken from it shall fairly represent the mass. The assayer, operating upon a small quantity of the assay piece which he has taken, determines by an exceedingly delicate chemical analysis the proportion of gold or silver or both which it contains. The fineness and the weight of the deposit after melting are the data for calculating its value. Deliveries of bullion, composed of these various deposits, are made from time to time to the melter and refiner, and are charged to him in account. It is his province to refine them, and convert them into ingots of standard metal, 900 thousandths fine, suitable for the fabrication of coins. Gold and silver in their pure state, on account of their softness, are altogether unadapted for coin. Consequently, each metal is alloyed with a certain quantity of some other metal baser than itself, to give it greater hardness and durability. In the United States silver, in the manufacture of silver coin, is alloyed with copper; the proportion in 1,000 being 900 parts silver and 100 parts copper; and in gold coin, 1,000 parts, 900 being pure gold, 100 alloy of silver and copper, of which not more than 50 parts is allowed by law to be of silver. In practice a very small fraction of this alloy is silver. By means of powerful but accurately constructed rollers, driven by steam, the ingots (which are bars sharpened at one end like the blade of a chisel, and about one foot long, three fourths of an inch to two and a half inches broad, and half an inch thick) are rolled into thin strips or ribbons of the proper thickness for the coin to be made, through the rollers exhibited in the drawing (fig. 4) just above the clock dial. This process is required to be gone through ten times for gold and eight times for silver. These strips must occasionally be annealed in furnaces, in order to soften them, before they are drawn, which latter operation is done by means of the drawing bench (fig. 5), in which they are drawn like wire through a steel gauge to make them straight and of uniform thickness. Next comes the cutting press (fig. 6), a vertical steel punch working accurately into a matrix or round hole in a steel plate of the size of the planchet required, and operated rapidly by an eccentric, under which

![Rollers](https://via.placeholder.com/150)
the strips are fed by hand. The gold planchets are subjected before coining to a careful adjustment by weight. This is done by women, whose delicacy of touch fits them admirably for this service. Seated at a long table, each one has a balance before her and a flat file in her hand; and the gold planchets are successively tried against a counter weight. Those that are too light are thrown aside to be remelted, and those that are too heavy are brought to the proper weight by moving the file lightly round the edge. The planchets are now ready for the milling machine (fig. 7), an American invention, by which the planchets, as rapidly as they can be fed by hand into a vertical tube, are caught one by one edgewise, and caused to rotate in a horizontal plane in a channel formed on one side by a revolving wheel, and on the other by a fixed segment of corresponding curve, but slightly nearer the wheel at one end than at the other. The effect is that each piece in passing through this narrowing channel has its edge evenly crowded up into a border or rim. After being annealed and cleaned or “whitened,” the planchets are ready for the coining press. The coining press (fig. 8) in use in all the mints of the United States is constructed after the plan of the French lever press invented by Thonneller. The pressure upon the die is effected by a lever moved by a crank and operating a toggle joint. The planchets being fed by hand into a tube or hopper in front of the machine, the lower piece in the tube is seized by steel feeders and carried forward and lodged in the collar between the upper and lower dies. At the same moment the lever is descending, and by the time the planchet is in position the toggle joint, brought into a vertical position, imparts to the piece a pressure which within the narrow limits of its motion is almost incalculable. The immediate relaxation of the joint causes the upper die to be lifted, when the feeders, coming up with a second planchet, push away the one already coined. The planchet before being struck is slightly less in diameter than
being carefully inspected by the coiner to eliminate defective pieces, are counted and put up in bags, and delivered to the superintendent, by whom the coiner is held to the same accountability as the melter and refiner. The counting is performed with great accuracy and despatch by a counting board of very ingenious construction. The dies used in all the mints of the United States are made under the supervision of the engraver of the Philadelphia mint. The production of original dies cut by the engraver's hand in steel is a work of great labor, and it would be impossible in this manner to supply the dies necessary for the coinage of the country. The original dies, being carefully finished and hardened, are used simply to strike copies in softened steel, which is done by repeated blows under a powerful screw press. As the devices upon the original dies were sunk, these copies will be in relief. To prepare dies for coinage, therefore, this hardening and copying process must be repeated. A rigid system of registration and accountability is necessary to keep the old dies from falling into improper hands.—In the various operations of the mint, particularly in those of the melter and refiner's department, a large amount of precious metals will be temporarily lost by becoming absorbed in the melting pots and fluxes and mixed with the ashes and débris of the furnaces. These materials are carefully gathered up, and the gold and silver extracted by various methods. The chlorination process of Prof. Miller of the Australian mint, for refining and parting the precious metals, has lately been introduced at the Philadelphia mint. Under the coinage act of 1853, provision is made for the purchase of silver bullion, and the gain arising from its conversion into coin of a nominal value exceeding the cost thereof is credited to a special fund called the silver profit fund. In adjusting the weights of gold coins the following deviations cannot by law be exceeded in any single piece: in the double eagle and the eagle, one half of a grain; in the half eagle, the three-dollar piece, the quarter eagle, and the one-dollar piece, one fourth of a grain; and in weighing a number of pieces together when delivered by the coiner, the deviations from the standard must not exceed \( \frac{1}{16} \) of an ounce in $5,000 in double eagles, eagles, half eagles, or quarter eagles, in 1,000 three-dollar pieces, and in 1,000 one-dollar pieces. In the silver coins the following deviations must not be exceeded: in the dollar, the half dollar, the quarter dollar, and the dime, one and a half grain; and in weighing large numbers of pieces together when delivered by the coiner, the deviations from the standard must not exceed \( \frac{1}{16} \) of an ounce in 1,000 dollars, half dollars, or quarter dollars, and \( \frac{1}{16} \) of an ounce in 1,000 dimes. In the minor coins no greater deviation is allowed than three grains for the five-cent piece and two grains for the three-cent and one-cent pieces.—During the year ending June 30, 1874, the amount of gold deposits at the mints and assay offices of the United States was $68,861,595; silver deposits and purchases, $15,122,151. Deducting the redisposals of bars made and issued by one institution and deposited at another, the deposits were: gold, $49,142,511; silver, $11,485,078. The amount in bars transmitted from the New York assay office to the mint at Philadelphia for coinage during the fiscal year was: gold, $18,704,101; silver, $2,613,036; total, $21,317,737. The distribution of the gold and silver bullion deposited and purchased, including receipts, was as follows:

The directors of the mint since its organization have been as follows: David Rittenhouse of Pennsylvania, July, 1792, to July, 1795; Henry DeSaussure of South Carolina, July 11 to Oct. 28, 1795; Elias Bondinot of New Jersey, October, 1795, to July, 1803; Robert Patterson of Pennsylvania, July, 1805, to July, 1824; Samuel Moore of Pennsylvania, July, 1824, to July, 1835; Robert M. Patterson of Pennsylvania, July, 1835, to July, 1851; George
N. Eckert of Pennsylvania, July, 1851, to April, 1853; Thomas M. Pettit of Pennsylvania, April to June, 1853; James Boss Snowden of Pennsylvania, June, 1853, to April, 1861; James Pollock of Pennsylvania, April, 1861, to October, 1866; William Milward of Pennsylvania, October, 1866 (not confirmed by the senate); Henry R. Linderman of Pennsylvania, April, 1867, to May, 1869; James Pollock of Pennsylvania, May, 1869, to April, 1873 (date of reorganization, since superintendent at Philadelphia); Henry R. Linderman, April, 1873. The present mint of France, a very complete and magnificent establishment, where probably the finest work of the kind in the world is done, was built in 1771 and the following years, and commenced work in 1775. In this mint, besides the operations connected with the public coinage and making of medals, the assaying of gold and silver is done for jewellers, who are obliged by law to have every article stamped before it can be sold. The coinage of gold from 1850 to 1872 was of the value of 6,917,507,383 francs, and of silver during the same period 843,821,298 francs.

MINTO, Gilbert Elliot, first earl of, an English statesman, born April 23, 1751, died June 21, 1814. He was the elder son of the third baronet, Sir Gilbert Elliot of Roxburghshire, Scotland, and entered the house of commons in 1774 as a liberal whig. He was ambassador at Copenhagen from 1788 to 1794, and was sent as viceroy to Corsica during the English occupation of that island in the earlier years of the war with the French republic. On his return to England he was raised to the peerage (Oct. 10, 1797) as Baron Minto. In 1799 he was appointed ambassador at Vienna. On resuming his seat in the house of lords, he urged the union of Ireland with England, and subsequently opposed the emancipation of the Irish Catholics. In 1806—7 he was president of the board of control for Indian affairs, and he was governor general of Bengal from 1807 to 1813, when he was made Viscount Melgund and earl of Minto (Feb. 24).—See "Life and Letters of Sir Gilbert Elliot, first Earl of Minto," by his grandson, the countess of Minto (London, 1874).—His son Gilbert Elliot-Murray-Kynynmound, second earl, born Nov. 16, 1782, was minister to Berlin in 1822, first lord of the admiralty 1835—41, lord privy seal in the administration of Lord John Russell (his son-in-law) 1846—52, and in 1847 was sent on a special mission to the Italian courts for the purpose of promoting liberal reforms. He died July 91, 1859.

MINUIT or Minuets (properly Minzwueil), Peter, an American colonial governor, born in Wesel, Germany, in the latter part of the 16th century, died near Fort Christiansa, Delaware, in 1641. He was a Protestant deacon in his native town, and on Dec. 19, 1625, was appointed by the Dutch West India company its director general in New Netherland, and landed on Manhattan island May 4, 1626. His first measure was to purchase the island from the aborigines for 60 guilders. He built Fort Amsterdam, and maintained the right of the Dutch against the claims of English supremacy over New Netherland. The colony prospered under his administration, but the West India company held him responsible for abuses which had led to the accumulation of landed property in the hands of the patroons, and he was recalled in August, 1631. He sailed in March, 1632. Stress of weather drove his ship into Plymouth, England, where it was attached at the suit of the council of New England, on a charge of illegally trading within the English dominions. The Dutch ambassador in London protested, but the ship was not released till May 27. Minuit, failing to regain his position under the West India company, offered his
services to the Swedish government in 1637, and toward the close of that year sailed from Copenhagen under the auspices of Oxenstiern, and with a commission from the queen of Sweden authorizing him to plant a new colony on the W. coast of Delaware bay. He anchored in Chesapeake bay in March, 1638, and soon began to build Fort Christina, 2 m. from the confluence of Minqua's Kill with the South river, near the present site of Wilmington, and despite the opposition of the Dutch he increased the settlement, which he called New Sweden. It was the first permanent European settlement of Delaware, and was annexed to the Dutch possessions in 1655.

**MINUTE (Lat. minutum), the 60th part of an hour; also used to denote a portion of the arc of a circle, and as a measure of angles. When the circumference of the circle is divided in 24 hours, the minute is \( \frac{T \pi}{15} \) part of the circle. When the circle is divided into 360\(^{\circ}\), the minute is the 60th part of a degree, consequently equal to \( \frac{T \pi}{15} \) of the circumference. To distinguish these two measures, the former is called a minute of time, the latter a minute of arc; 15 minutes of arc of a parallel of latitude being equal to one minute of time, and 4 minutes of time to a degree.—The term is used in architecture to indicate the 60th part of the diameter of the shaft of a column, measured at the base, and serves as a measure to determine the proportions of the order.

**MINOTULLI.** 1. Heinrich Mein von, baron, a German archeologist, born in Geneva, May 12, 1772, died near Lausanne, Sept. 10, 1846. He entered the Prussian army at an early age, was wounded during the campaign on the Rhine in 1793, and made professor in the military school in Berlin. In 1820 he led a scientific expedition to Egypt under the patronage of the Prussian government, and visited Thebes, and Asswan, whence he returned to Alexandria, reaching Berlin in August, 1822. The architect Liman, the naturalist Hemprich, and seven of his other companions had died on the journey, and a great portion of his collection was lost by shipwreck. The remainder of it was purchased by the king of Prussia. Minutoli passed his last years in Switzerland. He published *Betrachtungen über die Kriegskunst* (3d ed., Berlin, 1816); a narrative of his travels under the title of *Reise zum Tempel des Jupiter Ammon und nach Oberägypten* (1824—’77); *Beiträge zu einer künftigen Biographie Friedrich Wilhelms III.* (1843); *Militärische Erinnerungen* (1845); and various historical and archaeological works.—While in Italy he married in 1820 Wofradisz, countess von der Schulenburg, the widow of a Saxon officer, who accompanied him in his travels, and wrote in French an admirable work on Egypt (*Souvenirs d’Égypte*, 2 vols., Paris, 1826; German translation by Gersdorf, Leipzig, 1829).

**H. Julius von,** baron, son of the preceding, born in Berlin in 1805, died near Shiraz, Persia, Nov. 5, 1890. He became well known in 1846 by his discovery of the Polish conspiracy while he was director of police at Pozán. In 1851 he was appointed Prussian commissagent general for Spain and Portugal, and in 1856 ambassador to Persia. He wrote on jurisprudence and Prussian history, and most extensively on Spain and Portugal and the Canary islands. The principal of the latter works are *Altes und Neues aus Spanien* (2 vols., Berlin, 1854), and *Portugal und seine Colonien im Jahre 1854* (2 vols., Stuttgart, 1855).

**MIocene,** in geology, the intermediate of the three epochs of the tertiary or mammalian age, having the eocene below and the pliocene above. The term is derived from Gr. *μική*, less, and *αἰον, aion,* recent, from less than half its species being of living forms. Some geologists make a fourth division, called oligocene, by separating an upper portion of the eocene and uniting it with the lower section of the miocene. The beds of the miocene epoch are of either marine or fresh-water formation. The marine beds cover a large part of the Atlantic border of the United States, belonging to what is known in American geology as the Yorktown period. They are full of fossils, and occur at Gay Head on Martha’s Vineyard, in Cumberland co., N. J., on both sides of the Chesapeake in Maryland, and in Virginia at Yorktown, Suffolk, Smithfield, and other places. Fresh-water beds of miocene occur in the upper Missouri region, along the White river, called *mawaises terres* or “bad lands.” They constitute the “White river” group of Hayden, and have a thickness of 1,000 ft. and upward. In these beds are found the remains of the *Titanothereum,* which also occurs in the eocene. There are also in the Wind river valley and on the west side of the Wind River mountains other fresh-water deposits from 1,000 to 1,500 ft. thick, called the Wind river group. In California, on the opposite side of the continent on the miocene formation consists of sandstone and shale, in some places attaining a thickness of 4,000 or 5,000 ft. They occur near Astoria on the Columbia river, and also in the coast ranges both north and south of San Francisco, in the Santa Inez mountains, and at various other places.

**MIOLAN- CARVALHOS.** Caroline Marie Félix, a French singer, born in Marseilles, Dec. 31, 1831. She studied under Delarte and subsequently under Duprez at the Paris conservatoire, where she obtained the first prize after having appeared in the first act of *Lucia di Lammermoor* and the second act of *La Juive.* In 1856 she won great applause in *D’Ambassade- drice* at the Opéra Comique. In 1853 she married M. Léon Carvalho (Carvaillé), who became manager of the Théâtre Lyrique, with his wife as the leading prima donna. She performed with brilliant success in London in 1859, as successor of Mme. Bosio. Her chief rôles are Margaret in “Faust,” Dinorah, Juliet in “Roméo et Juliet,” Zerline in “Don Juan,” and Rosine in “The Barber of Seville.”
MIOT, André François, count de Melito, a French author, born in Versailles, about 1782, died in Paris, Jan. 5, 1841. He was connected with the ministries of war and foreign affairs and the diplomatic service, and was councillor of state under the empire, minister of war and the interior under Joseph Bonaparte in Naples, and intendant of his court in Madrid. In 1835 he was admitted to the French academy. His principal works are: a translation of Hiero- dotus with a life of Homer attached (3 vols., Paris, 1822; Bibliothèque historique de Diodore de Sicile, a translation containing all new fragments of the works of Diodorus (7 vols., 1835–5); and his posthumous Mémoires sur le concours, l'empire et le roi Joseph (3 vols., 1858).

MIQUELON. See Saint-Pierre.

MIRABEAU, Gabriel Honoré Riqueti, count de, a French author and statesman, born on his father's estate of Bignon, near Nemours, March 9, 1749, died in Paris, April 2, 1791. A huge-headed infant, who had come into the world with a pair of grinders, one foot twisted, and tongue-tied, disfigured when three years old by confluent smallpox, he grew up *as ugly as the nephew of Satan,* but giving signs of bodily strength, passionate temper, and intellectual power. His father was a philanthropist and the author of a work entitled L'Ame des hommes, but was a tyrant at home, and tried to subdue his son by severity and contempt. The boy was educated at first by private tutors, and then was entered at a military school in Paris, under the assumed name of Pierre Buffière, because his family were ashamed of him. On July 19, 1767, his father placed him as a volunteer in the Berry regiment of cavalry, under a colonel notorious for his severity. He contracted a few debts, lost 40 livres at the gaming table, and surpassed his colonel in the affections of a young girl at Saintes. These offenses begat upon him the wrath of his father, who in the autumn of 1768 banished him by a lettre de cachet to the fortress on the isle of Ré. Here he made a friend of his jailer, who reported favorably concerning him, and his father procured him a commission as second lieutenant in the regiment of Lorraine, which was sent to Corsica in 1769. During a year of hard service he evinced such alacrity, courage, and fidelity as to command the esteem of his officers and the affections of his comrades. On his return he was sent to his uncle, the bailli of Mirabeau in Provence, who undertook to conciliate his father. At last Mirabeau was allowed to assume his true title, and was presented at court. By his father's advice he married, June 22, 1772, Marie Émilie de Cuvet, the only daughter of the marquis of Marignane. She had no portion, and he soon became involved in pecuniary difficulties. His father not only declined to help him, but prevented the marquis of Marignane from doing so, and on Aug. 28, 1774, imprisoned him in the castle of If at Marseilles; and when his wife and family prayed for his release, he had him removed, May 25, 1775, to the fort of Jouj, in the Jura mountains. Being allowed occasionally to visit the neighboring town of Pontarlier, Mirabeau fell in love with Sophie, marchioness de Montler, the young and gifted wife of an old magistrate. In August, 1776, he eloped with her to Verrières, Switzerland. A few weeks later they were in Amsterdam, where Mirabeau, under the fictitious name of Saint-Mathieu, tried to make a living by writing for Dutch publishers. He made some translations from the English, and wrote his Avis aux Hessois, a pamphlet against the Hessian sale of soldiers to England for service in the American war. On May 10, 1777, he and his paramour were condemned by the tribunal of Pontarlier, he being sentenced to be beheaded for "forcible abduction and seduction," while she was condemned to imprisonment for life. On May 14 they were arrested and taken to Paris; he was imprisoned at Vincennes, and she was sent to a convent at Gien. His father had resolved to keep him a prisoner for life. In his dungeon he constantly wrote love letters to Sophie (a favor which had been granted to him by the chief of police, as the only means of preventing his suicide), and accomplished a good deal of literary work, the most important part of which was his Lettres de cachet et prisons d'état. In spite of the fact that he was attacked by several serious diseases, and was losing his eyesight, his father was deaf to all appeals, until the death of his little grandson suggested the "necessity of perpetuating the family," and Mirabeau regained his liberty Dec. 18, 1780, after an imprisonment of three years and a half. He at once set to work to settle a warfare that had been going on between his parents for many years; but here he failed. His mother was forever alienated from him by the success which she obtained in her lawsuit against her husband was followed by a reconciliation between father and son, May 20, 1781. Meanwhile Mirabeau had had an interview with Sophie; but jealousy had sprung up between them, they parted in anger, and in 1789 she committed suicide. An attempt at reconciliation with his wife was unsuccessful, and he resorted to legal proceedings for her recovery. These he conducted himself, with marked ability and eloquence. His pleadings before the parliament of Aix created deep emotion among the people of that city, the majority of whom sided with him; but one half of the judges were relatives of Marignane, and the court decreed, July 5, 1788, that the wife should remain separated from her husband. Though defeated, Mirabeau became a popular idol. After a futile attempt to appeal the suit, he went to England, where he published his Considerations sur l'ordre de Cincinnati, and his Doutes sur la liberté de l'Excout, a defence of the Dutch monopoly against the designs of the emperor Joseph II. He returned to Paris in April, 1785, and wrote several able pamphlets on financial subjects. At the close of this year

561 VOL. XI.—40
he visited Berlin, where he published a pamphlet upon Cagliostro and Lavater, and Moses Mendelssohn, ou la Réforme politique des Juifs. After paying a short visit to Paris, he returned with a secret mission from the French ministry. For six months he held a semi-official correspondence, and accumulated materials for a great work upon the Prussian monarchy. In 1787 he returned to France, and wrote a pamphlet, Dénonciation de l’agitation, directed against Calonne, and followed some time after by a similar attack on Necker’s policy. Being threatened with another lettre de cachet, he went to Brunswick, where he completed his work De la monarchie prusienne, which was published the next year (8 vols. 8vo and 4 vols. 4to). With the exception of the few months of his mission to Prussia, he had recently been greatly embarrassed by pecuniary difficulties; but now he found himself in the most wretched situation, and it was probably under the pressure of sheer penury that he published, under the title of Histoire secrète de la cour de Berlin, his confidential letters to the French ministry. This publication was ordered to be burned by the executioner. The convocation of the states general being now announced, he went to Provence in the beginning of 1789, and presented himself for election to the nobility of this province; but he soon drew upon himself their implacable hostility by his boldness in the discussions as to the mode of election. He was finally expelled from their assembly, as having no fief of his own, and threw himself into the arms of the third estate. Several times he was called upon by the authorities to exhort the people during riotous disturbances. He was elected to the states general for both Marseilles and Aix, and decided to sit for Aix. In the assembly he never had a party; but by logic and eloquence he always held it at whatever important occasion. He encouraged the third estate to maintain their rights against the pretensions of the other orders, and at the end of the royal sitting of June 23 he sent the grand master of ceremonies back to the king with this bold answer: “Go and tell your master we are here by the power of the people, and that we are only to be driven out by that of the bayonet.” But, detesting mob license no less than tyranny, he advocated the royal prerogative of the veto, and, while “utterly opposed to a counter revolution,” declared himself ready to make an effort for “the restoration of the king’s legitimate authority as the only means of saving France.” In consequence of this, part of his debts, about 80,000 francs, were secretly paid by order of the king, and he received a monthly pension of 6,000 francs. He also received four notes of 250,000 francs each; but these were given back to the king at Mirabeau’s death. This has been cited as evidence of his venality, though he pursued a line of policy dictated by his convictions. On May 20, 1790, in an elaborate oration, he supported the king’s right to declare peace or war, in opposition to several celebrated orators, and especially Barnave, whose popularity was now more than equal to his own. Barnave was borne in triumph, while Mirabeau was charged with treason and corruption. Three days later he ascended the tribune, defended himself with fervid and convincing eloquence, and came out triumphant. The mass of business which Mirabeau now carried on simultaneously was prodigious. In addition to his duties as a deputy, he published a journal, which, first under the title of Journal des États Généraux, then Lettres à nos Constituants, and finally Courrier de Provence, gave a report of the sittings, and freely discussed all the questions of the day. In these labors he called around him coadjutors, such as Dumont, Duroveray, Reibez, and others, who not only wrote for his periodical, but assisted him in the preparation of documents, and even of his speeches. But his strength became exhausted by his herculean labors, rendered still more dangerous by high living and licentiousness. On March 27, 1791, though very ill, he occupied his seat in the assembly and spoke five times. When he went home, his friend and physician Cabanis saw that his end was approaching. The news of his illness spread over Paris like a public calamity; and in the chaussée d’Antin, the street in which he lived, was thronged by the multitude; bulletins were printed and distributed every hour; twice a day the king sent to his house for tidings. After a night of terrific suffering, at the dawn of day he addressed Cabanis: “My friend, I shall die to-day. When one has come to such a juncture, there remains only one thing to be done; that is, to be perfumed, crowned with flowers, and surrounded with music, in order to enter sweetly into that slumber from which there is no awaking.” He ordered his bed to be brought near the window, and looked with rapture at the brightness of the sun and the freshness of his garden. His death was mourned by the whole nation; every one felt that the ruling spirit of the revolution had passed away. His body was carried in pomp by the assembly and the people to the church of St. Geneviève; but three years later, by order of the convention, it was removed to the churchyard of St. Catherine, the burial place of criminals.—Editions of Mirabeau’s works have been published by Barthe (8 vols. 8vo, Paris, 1819—20), and by Mérihon (9 vols. 8vo, 1823—7); but neither of these collections is complete, while their biographical notices are far from correct. Many of his productions have had but one edition, and are now difficult to find. The Mémoires biographiques, littéraires et politiques de Mirabeau, by Lucas Montigny, his adopted son (9 vols., 8vo, Paris, 1834—5), are as yet, in spite of serious defects, the most valuable source of information on the subject. See also Correspondance entre le comte de Mirabeau et le comte de La Marek pendant les années 1789, 1790 et 1791 (3 vols., Paris, 1851); Dumont’s
posthumous Souvenir (1831); Schneidewind's Mirabeau and his Life (Leipsic, 1831); "Mirabeau, a Life History" (London, 1848); Ver- morel, Mirabeau, sa vie, ses opinions et ses discours (5 vols., Paris, 1864—6); Reynald, Mirabeau et la constituant (Paris, 1872); and Loménie, Mirabeau et son père (Paris, 1874).

MIRACLE (Lat. miraculum, from mirari, to wonder), in the stricter usage of the word, a work of divine power, interrupting (or violating) the ordinary course of nature, and directly designed to attest the divine commission of him who works the miracle. In the Scriptures of the Old and New Testament, both the τέρατα, or prodigium, and the σημεῖα, or sign of divine power, are included in the general idea of miracle, but not dissociated. In the New Testament these words (τέρατα, δηνῶμεν, σημεῖα) are used to express the supernatural acts and occurrences by which the character and mission of Christ and his apostles were declared and attested. The first is the most general and indefinite, properly an extraordinary and portending phenomenon, something monstrous and out of the course of nature. The second is more specific, implying the possession of supernatural power, through which such acts were performed. The third is still more specific, expressing the object of such acts, namely, as signs or indications by which something is made known. Christ says: "The works that I do bear witness of me, that the Father hath sent me." Augustine, De Civitate Dei, 21, 8, argues that a miracle is not against nature in its highest aspect: "How is it that against nature which comes from the will of God, since the will of such a great Creator is what makes the nature of everything?" Abéard maintained that, in relation to the divine omnipotence, nought is miraculous. Aquinas sharpens the contrast between the miraculous and the natural. The schoolmen set up two criteria of miracles: that they are, 1, above the ordinary course of nature; 2, by the power of God. After the reformation, in connection with the progress of modern philosophy, both physical and metaphysical, the necessity of yet further distinctions and limitations became manifest. Bacon in his "Advancement of Learning" asserts: "There never was a miracle wrought by God to convert an atheist, because the light of nature might have led him to confess a God; but miracles are designed to convert idolaters and the superstitions, who have acknowledged a deity but erred in his adora- tion; because no light of nature extends to declare the will and worship of God." Spinoza in his Tractatus Theologico-politicus led the way in the historical criticism of the Biblical narra- tives, on the basis of the definition: "A mira- cle signifies any work the natural cause of which we cannot explain after the example of any- thing else to which we are accustomed; or, at least, he who writes about or relates the mirac- le cannot explain it." German rationalism, in its earlier form, attempted the explanation of the gospel miracles by material and spiritual causes. Some alleged that Jesus had unusual knowledge of the powers of nature, or effected his cures by his spiritual influence over men's souls. Others, as Paulus, explained them by the supposition that the disciples confounded natural events with supernatural; e. g., the two angels in the tomb, clad in white, were an illusion caused by linen garments hanging there; or by such violent interpretations as that the walking upon the sea meant walking on the border of the sea. Some, again, found in them only a symbolical and allegori- cal sense, and interpreted them as images of spiritual truths. In the mythical theory of Strauss they are denied as facts, and explained, not as wilful deceptions, but as a spontaneous expression of popular religious feeling, ascrib- ing to Christ what is false in fact, but true in some very general philosophical idea. As to the position of miracles in the evidences, some divines, in the reaction against rationalism, have laid the chief stress upon these external signs of divine power, making the miracle to be the main source of an undoubting belief, while others put the truth of the doctrine in the front rank, and made the doctrine the test of the miracle, rather than the miracle the proof of the doctrine. Thus Dr. Wardlaw would test the doctrine by the miracle, while Dean Trench advocates the converse order. But it seems difficult, and even illogical, to construct on this point an absolute dilemma; for, on the one hand, the mind receives a spiritual and divine truth on its own evidence, and for its own sake; while, on the other hand, all who are enlisted in this debate allow that miracles have an important position in the external evidences for the Christian faith. For a full discussion of miracles, see Douglas, "Criterion, or Miracles Examined" (London, 1794); Campbell, "Dissertation on Miracles" (Edinburgh, 1768); Farmer, "Dissertation on the Miracles" (1771); Leland, "View of Deistical Writers" (1795); Schleiermacher, Der Christliche Glaube (Berlin, 1821—2); Strauss, Das Leben Jesu (Tübingen, 1835; abridged ed., 1864; English translation, 1865); Tholuck, Glaubenswürdigkeit der evangelischen Geschichte (Hamburg, 1887), and on the miracles of Mohammed and those in the Catholic church, in his Vermischte Schriften (1839); Leslie, "Truth of Christianity" (1848); Wardlaw, "On Miracles" (1855); W. L. Alexander, "Christ and Christianity" (New York, 1854); N. W. Taylor, "Lectures on Moral Government" (1850): McCosh, "The Supernatural in relation to the Natural" (New York, 1869); Mozley, "Bampton Lectures on Miracles" (London, 1865); G. P. Fisher, "Essays on the Supernatural Origin of Christianity" (New York, 1865); the duke of Argyile, "The Reign of Law" (London, 1866); and "Christianity and Skepticism," the Boston lectures for 1870 (Boston, 1870). On the con- tinuance of miracles in the church, besides the works of Blunt and Bishop Kaye, see Middle-
MIRACLES AND MORALITIES, religious and allegorical plays, which constituted the drama of the middle ages. They were often called miracle plays and moral plays, and in later times have more frequently been indiscriminately styled mysteries. The subjects of the miracles were either the narratives of the Bible or the legends chiefly of the lives of the saints; and the moralities, which appeared later, intermingled allegory with sacred history, or were represented exclusively by allegorical personages. In the first ages of Christianity baptism was refused to any one concerned with the theatre, and both the Greek and Latin fathers anathematized the dramatic art. In the 4th century the church succeeded in extinguishing the theatre everywhere except in Constantinople, where the genius and the arts of antiquity lingered in decay. This triumph had hardly been accomplished when from the bosom of the church sprang a new drama and spectacle. The emperor Julian ridiculed the asceticism of the church by a law forbidding any Christian to be taught in heathen learning. Apollinaris, presbyter of Laodicea, and his more celebrated son of the same name, bishop of that see (died about 390), were fine classical scholars. The former versified the Pentateuch and the history of Israel, and the latter paraphrased the gospels after the manner of the dialogues of Plato. Soon the sacred ceremonies and commemorations of the Christian faith, in the name of which profane games had been proscribed, were transformed into dramatic representations. Gregory Nazianzen, patriarch of Constantinople, is the reputed author of a play on Christ's passion, and of others of the same kind, written to supersede those of Sophocles and Euripides. The progress of this Christian drama cannot be traced till about the 11th century, when Theophylact of Constantinople introduced the feast of fools, the feast of asses, and other religious pastimes, which were celebrated in churches. To these sports the clergy added the acting of miracle plays, which originally were not only composed by ecclesiastics, but were performed by them in churches and the chapels of monasteries. They were afterward exhibited by companies of tradesmen, each guild sharing the expense and undertaking a portion of the performance; and they served the purpose of amusing the people on public occasions and festivals, while the clergy were at length forbidden by popes and councils to take any part in them. Jugglers and minstrels attended the travelling companies. The stages, either temporary or portable on wheels, usually consisted of three platforms, one above another. On the uppermost sat the Pater Caelumis, surrounded by his angels; on the second appeared the saints and glorified men; while living men occupied the lowest. On one side of the stage was a dark, pitchy, flaming cavern, from which issued hideous howlings, as of souls tormented by demons; its occupants were the greatest jesters and buffoons of the company, who frequently ascended upon the stage to act the comic parts. It is probable that miracles were introduced, perhaps by returning pilgrims, from Constantinople into Italy, and thence into France and England. The oldest known are in Latin, but in the 12th and 13th centuries they became common in the modern languages; and with some exceptions there is a general resemblance in subjects, characters, and theatrical machinery between those of different countries. They probably had a common origin, and were introduced about the same date, being communicated from one religious body to another. Three Latin miracles written early in the 12th century by Hilarius, a disciple of Abéard, are extant; the subjects are the raising of Lazarus, the life of St. Nicholas, and the history of Daniel. The miracle of St. Catharine, by Geoffroy, abbot of St. Albans, was performed in Dunstable, England, and in Paris about the same time, and it was then no novelty. Other Latin plays are preserved which seem to have been very popular, both as scholastic exercises among the younger monks, and as popular exhibitions, the greater part of the story being told by pantomime. The mystery of the wise and foolish virgins, in which Latin and Provençal are used alternately, indicates the period of transition to the vernacular languages, and may stand at the beginning of European dramatic literature.—The miracle of the passion was one of the earliest and most wide-spread, and from it the first theatrical company of Paris, established in 1402, was called the brethren of the passion. It embraced the principal events in the life of Christ, was exhibited with splendid pomp, and its representation occupied several days. Among its characters were the three members of the Trinity, angels or archangels, the apostles, devils, and Herod with all his court. The Virgin Mary is a favorite character in French mysteries, and several of them bear the title of miracles de Notre Dame. Others are entitled mysteries of the conception, of the nativity, of the resurrection, and of divers events in the legends of the saints and in the narratives of the Old and New Testaments. The splendor of the theatrical decorations and appliances for inspiring terror increased during the 15th century. In one of the Parisian mysteries St. Barbara was hung up by the heels on the stage, and, after uttering her monstrosities, was torn with pincers and scorched with lamps before the audience. In a mystery exhibited at Montz in 1437, an immense dragon sprung
out of hell, and threw the spectators into con- 

sternation by spreading his wings close by them. The mystery of the "Acts of the Apostle 

ses" was acted for many successive days in 

1541 before the nobility, the clergy, and a large 

popular assemblage in Paris. The dramatis 

personae are God the Father, Son, and Holy 

Ghost, the Virgin and Joseph, archangels, an 

gels, the apostles and disciples, Jewish priests, 

emperors, philosophers, magicians, Lucifer, 

Satan, Beelzebub, Beilai the attorney general 

of hell, Cerberus the porter, and a multitude of 

other personages, amounting altogether to 485. 

A large number of French miracles exist in 

manuscript, and many have been printed or 

reprinted during the present century.—The 

Germans have numerous miracle plays, two of 

which cannot be traced in the contemporary 

productions of other European nations. The 

subject of the first of these is Dr. Faustus, 

which represents the life, death, and damna- 

tion of a daring libertine. The subject of the 

second is the canonization of Pope Joan, which 

was written in 1480 and attained general pop- 

ularity. It has 25 characters, among which 

are the devil and his mother Lilis, three good 

gangs, the Virgin Mary, her Son, Pope Basil, 

four cardinals, a Roman senator, and Death. 

The scene shifts between earth, hell, purga- 

tory, and heaven. It begins with a council of 

devils, who agree to tempt Jutta, the heroine, 

to profane the papacy. She assumes boy's 

clothes, accompanies a young clerk to the uni- 

versity of Paris, acquires a doctor's degree, 

goes to Rome, and is made successively car- 

dinal and pope. The Virgin Mary sends an 

angel to ask Jutta whether she prefers perdi- 

tion or penance and final pardon. She resolves 

to repent, but death suddenly seizes upon her 

soul while she is lying-in, and carries it to the 

devils in hell. The Virgin again intercedes, 

and sends an angel from the throne of grace 

to release her from torment. The play ter- 

minates with the magnificent spectacle of her 

ascension into heaven. Germany was celebra- 
ted for its Fastnachts spiele, or carnival plays, 
in which religious subjects were treated with 

unbounded license. In one of them, which is 

extant, Virgil accompanies the shepherds to 

adore the new-born Christ.—The records of 

English miracle plays are at least as ancient as 
those of France or Germany. Their early 

popularity is attested by Langland and Chau- 
er, and subsequently immense crowds assem- 
bled with the greatest enthusiasm to witness 
their performance. They may be traced from 
the beginning of the 12th century, but whether 
they were originally in Latin or in Norman 
French is not certain. Higden, who wrote, 
translated, or compiled the Chester plays in 
1288, is said to have been obliged to visit Rome 
three times before he could obtain leave to 
have them acted in the English tongue. The 
Chester, Coventry, and Towneley mysteries 
form three great series. As early as 1268 re-

ligious dramas were exhibited by the incorpo-
library three miracle plays in the Digby manuscripts relating to the conversion of St. Paul, and two manuscripts containing the Cornish plays of the deluge, the passion, and the resurrection. Only a single example of the Newcastle mysteries remains, entitled "Noah's Ark, or the Shipwrights' Ancient Play," in which God, an angel, Noah and his wife, and the devil are the characters. According to Malone, the last mystery performed in England was that of Christ's passion in the reign of James I., but other authorities say they were acted in churches, and even on Sunday, as late as the reign of Charles I. They had, however, generally ceased to be written from the time of John Bale (1538). The principal English miracle plays have been published, and no other portion of medieval literature is so strikingly marked by mingled drollery and solemnity. — From the reign of Henry VI., miracles had been enroached upon and superseded by moral plays or moralities, in which abstract allegorical personages took the place of Scripture characters. The change was gradual. In one of the Coventry miracles the representatives of Veritas, Justitia, Paz, and Minercordia appear in the parliament of heaven. Death and the mother of Death were successively added; and as these characters increased, Biblical history fell into the background and was at length eliminated. Moralities reached their highest perfection in the reigns of Henry VII. and Henry VIII., though they subsequently exhibited greater complication and ingenuity. They contained two standing characters, the Devil and the Vice. The former, the leader of the Seven Deadly Sins, was made as hideous as possible, shaggy, bottle-nosed, and with a tail. He entered upon the stage crying "Ho, ho, ho!" and his part consisted largely in roaring when castigated by the Vice. The latter, though represented as "most wicked by design and never good by accident," was chiefly employed in belaboring the Devil. He was generally of the fool's habit, and the character was gradually blended with that of the domestic fool. Morality was abundant in France and England in the 15th and 16th centuries. The interlude of John Heywood marks the transition in England from them to legitimate tragedy and comedy. In Paris the devout buffoonery of the brethren of the passion gave offence and caused their suppression in 1547, and the company which purchased the Hôtel de Bourgogne was enjoined to abstain from "all mysteries of the passion, or other sacred mysteries." In French the Moralité tres singulière et tresbonne des blasphémateurs du nom de Dieu is one of the most celebrated; and in English Skelton's "Magnifrycence," designed to show the vanity of worldly grandeur, in which the characters are Felicity, Liberty, Measure, Adversity, Poverty, Despair, Miscifel, GoodHope, Redress, Circumspection, Perseverance, Fanacy, Folly, and Crafty-conveyance. — Mysteries are still occasionally performed at several places in Europe, the most celebrated being that of Ober-Ammergau, in southern Bavaria, which is represented every tenth year. (See Ober-Ammergau.) — See Onésime Le Roy, Études sur les mystères (Paris, 1837); Achille Joubalin, Mystères inédits du quinzième siècle (2 vols., Paris, 1837); Heinrich Hoffmann, Fundgruben für Gescichte deutscher Sprache und Literatur (Breslau, 1830–37); "The Chester Mysteries" (London, 1818); William Hone, "Ancient Mysteries Described" (1825); Thomas Sharp, "A Dissertation on the Pageants or Dramatic Mysteries anciently Performed at Coventry" (Coventry, 1825); Collier, "History of English Dramatic Poetry" (3 vols., London, 1831); "Ancient Mysteries from the Digby MSS." (Edinburgh, 1835); "The Towneley Mysteries," published for the Surtees society (London, 1836); William Marratt, "A Collection of English Miracle Plays" (Basel, 1888); Thomas Wright, "Early Mysteries, and other Latin Poems of the 12th and 13th Centuries" (London, 1888); Edwin Norris, "The Ancient Cornish Drama" (Oxford, 1859); and H. N. Oxenham, "Ober-Ammergau in 1871" (London, 1871). A large number of the French miracles and moralities have been published separately, among which are Les blasphemateurs (1831) and La vendedion de Joseph (1835), both exact reproductions in form and type of the manuscripts in the national library. —

...
MIRAGE

4, a combination of the two preceding, in which there are appearances of objects both erect and inverted. The causes, in many instances, are not easy to assign definitely. The mirage of the desert and the appearance of an inverted image of an object over the surface of water are usually explained as follows. In the first case the aerial strata decrease in density from above downward, in consequence of the cooling of the upper strata from radiation, and the warming of the lower by the hot sand.

Let fig. 1, in which the curves are exaggerated, serve for explanation. By referring to the article Loom it will be seen that in refraction there is a certain angle at which a ray of light, having passed through one medium, on coming to the surface will not pass out of the medium into the next and suffer refraction, but will be totally reflected back into the first medium. This angle is called the critical angle, or angle of total reflection, and varies with different media. Now an effect analogous to this may take place when a ray of light is passing through different strata of air at a very small angle, which at last becomes reduced to a degree or part of a degree which may be called the critical angle. Suppose the aerial strata in fig. 1 to decrease in density from a to d; a ray of light coming from the object will be refracted from the perpendicular in passing downward through the stratum a, still more in passing through b, and so on until it penetrates a stratum, which we will suppose is d, where the critical angle is reached, and the ray becomes totally reflected. The direction of the ray will then be upward, but will be refracted toward the perpendicular as it passes through successive strata of increasing density, so that when the ray reaches the eye the object will appear in the direction of e. In the second case, which takes place over the surface of water, and where the lower strata of air are cooled by the water so as to be denser than the upper, the course of the rays is shown in the exaggerated drawing in fig. 2. A vessel which may be so distant as to be partly or entirely hidden by the curvature of the earth, will appear inverted above the horizon when the rays of light are at first refracted from the perpendicular until the critical angle is reached at the stratum d, when total reflection takes place, by which the ray is given an inclination downward, so that the object appears in the direction of e. Simple looming, in which the object is seen in an erect position, will take place when the rays of light from it reach the eye before total reflection takes place, or before the critical angle is reached. When the object is seen both in an inverted and erect position, the case is, as has been remarked, a mixed one, and explainable by the examples already given.

When the strata are regular, the inverted will be above the erect image; but inequalities sometimes exist which cause, it is said, a contrary appearance, and lateral mirage may sometimes be produced in consequence of strata of different densities lying in a vertical position, as when a stratum of air is heated by a wall which is exposed to the rays of the sun. It is said that on the lake of Geneva boats have been seen doubled from the unequal density of two contiguous columns of air, more or less saturated with moisture, one being on the point of forming a fog. Many remarkable cases of mirage and looming have been recorded. In 1822, in the arctic regions, Captain Scoresby recognized by its inverted image in the air the ship Fame, which afterward proved to be at the moment 17 m. beyond the visible horizon of the observer. Dr. Vince, on Aug. 6, 1806, at 7 P.M., saw from Ramsgate, at which place usually only the tops of its towers are visible, the whole of Dover castle, appearing as if lifted and placed bodily on the near side of the intervening hill. So perfect was the illusion, that the hill itself could not be seen through the figure. The phenomenon called fata Morgana is a complicated case of mirage. (See FATA MORGANA.)

MIRAMICHI, a bay and river of New Brunswick. The bay is about 21 m. long and 20 m. wide at its mouth, Blackland point being on the north and Esquimac point on the south. It contains Fox and Portage and a number of smaller islands. The river is formed by the junction of two branches about 50 m. from the sea. At its mouth, which is obstructed by a sand bar, are landing places for cargoes, but the chief business places are Newcastle and Chatham, 20 m. up the stream. It is navigable for a distance of 40 m., from its mouth. Great forests of pine cover the banks of the river and the surrounding country. In 1825 a conflagration destroyed the forests on the N. bank and all the towns and villages within an extent of 85 m. long, and in some parts as much as 25 m. broad. The smoke and cinders were seen at Quebec, more than 250 m. distant, and as
far S. as Bermuda. The pines in the burned district have been succeeded principally by poplar, white birch, and maple.

MIRAMON, Miguel, a Mexican soldier, born in the city of Mexico, Sept. 29, 1832, shot at Querétaro, June 19, 1867. He was of French descent. In 1846 he entered the military academy at Chapultepec, and in September, 1847, participated with his classmates in the defence of Molino del Roy and Chapultepec against the Americans. He was wounded and taken prisoner, but after the treaty of peace returned to the academy and completed his studies. Entering the army in 1852, he was often engaged in suppressing local insurrections in the states of Jalisco and Mexico, until in October, 1854, he was sent with the rank of captain in the expedition against Alvarez, who had pronounced for the plan of Ayutla. He distinguished himself in several actions, especially in that of Temazcalo, for which he was promoted (July, 1855) to a colonelcy. A few weeks later, on the accession of Alvarez to the presidency, the regular army was placed under the control of its late enemies. This was so irksome to Miramon that in December, being sent as second in command of an expedition against the rebels of Zacapoaxtla, he imprisoned his superior, and with the entire force joined the pronunciados, leading them soon after to Puebla, which city submitted without resistance. In the memorable siege of Puebla, March, 1856, Miramon was the soul of the defence; and six months later he again pronounced at Puebla against Comonfort, defending that city a second time for 45 days against 10,000 besiegers. Escaping just before the capitulation, he engaged in a guerilla warfare, capturing Toluca in January, 1857. He was soon after wounded and made prisoner, but escaped in September, rejoined the revolutionists of the south as second in command, seized the town of Cuernavaca, and held it until the outbreak of the final movement against Comonfort headed by Zuloaga. During the fighting in the streets of Mexico in January, 1858, Miramon hastened thither with Osorio, and took by storm the Hospicio and the Acordada, thus deciding the withdrawal of Comonfort and the accession of Zuloaga to the presidency. Miramon was now, at the age of 25, made a brigadier general. Already the idol of the reactionary or church party, he was its most conspicuous leader in the three years' "war of reform" which commenced at this time. In March he gained the battle of Salamanca, which led to the flight of Juarez from the country and the surrender to the conservatives of the chief cities of the interior. He defeated the liberal coalition in the important battles of Ahualulco (September) and Atequiza (December), besides scores of minor engagements. The news of the battle of Atequiza having reached Mexico at a moment when a junta was engaged in the election of a president to succeed Zuloaga, overthrown by the plan of Navi-dad a few days before, Miramon was chosen, Jan. 2, 1859. He came at once to the capital, but declined the presidency and reinstated Zuloaga. The latter voluntarily retired from office a few days later, appointing Miramon president ad interim. Taking possession of the government on Feb. 2, Miramon soon placed himself again at the head of the army, with which he laid siege to Vera Cruz, then the capital of the liberal government of Juarez. Obliged to raise the siege in April, he returned to Mexico in time to witness the battle of Tacubaya, in which Gen. Marquez defeated the forces of Degollado. The execution of the prisoners of Tacubaya, including many non-combats and several medical students (April 11, 1859), is the chief blot upon the character of Miramon. With alternate successes and reverses, the war of reform was prolonged until the close of 1856, when the decisive battle of Calpulalpan (Dec. 22) opened the gates of Mexico to the liberal army under Gonzalez Ortega, and Miramon was forced to seek safety in flight from the country. In 1862 he attempted to return under cover of the intervention, but was not permitted by the allies to land at Vera Cruz. The succeeding years he passed in Europe. He approved the choice of Maximilian as emperor, but was requested to remain abroad in the nominal discharge of diplomatic functions, in order that his popularity might not embarrass the imperial administration. At the close of 1866, when it was believed that Maximilian was about to resign, Miramon returned to Mexico along with Marquez. As the result of conferences at Orizaba, Maximilian abandoned the intention of abdicating, returned to Mexico, placed Miramon and Marquez at the head of his diminished army, and with them and Mejia undertook the desperate campaign of Querétaro. Captured on May 15, 1867, Miramon was tried and condemned by a military commission, and was shot on the Cerro de las Campanas, along with Maximilian and Mejia. He left a widow and several children, who reside in Austria.

MIRANDA, Francisco, a Venezuelan revolutionist, born in Caracas about 1754, died in prison in Cadiz, Spain, July 14, 1816. He entered the Spanish army at an early age, and at 17 was captain in the Guatemala troops. He was in the French service in the American revolutionary war from 1779 to 1781, and conceived the idea of freeing the South American colonies from Spain. He went to South America in 1783, but his plans were discovered and he fled to Europe. After extensive travels, partly on foot, he then entered the French service as general of division, took part in the campaign of 1792, and in 1793 accompanied Dumouriez to Belgium, where he commanded a division of the army at Neerwinden. He was held responsible for the loss of that battle, and was accused of being implicated in the treason of Dumouriez, and brought before the revolutionary tribunal, but acquitted. He soon
again gave umbrage to the revolutionists, and was compelled to seek refuge in England. In 1805 he returned to France, but was again expelled from the country by the first consul. In 1806 he fitted out an expedition in the United States, enlisting many Americans, and returned to South America, with the view of establishing a republic at Caracas, but was not successful. Toward the close of 1810 he again went to South America, during the disorder of the Spanish government and maintained himself at the head of an army of insurgents; but he was delivered by Bolivar (July 31, 1812) into the hands of the Spaniards, and carried to Cadiz, where he died after four years' imprisonment. See "History of Miranda's Attempt to effect a Revolution in South America" (New York, 1808).

MIRANDOLA, Giovanni Pico della, count and prince of Concordia, an Italian scholar, born at Mirandola, Modena, Feb. 24, 1463, died in Florence, Nov. 17, 1494. Almost from childhood he displayed an extraordinary memory. At the age of 14 he was sent to Bologna to study canon law; but he soon went to Ferrara and applied himself to philosophy, theology, and languages, acquiring a knowledge of Latin, Greek, Hebrew, Chaldee, and Arabic, and the different systems of philosophy. After mastering all the learning of the time, he went to Rome in 1486, and propounded there 900 theses as subjects of controversy. His challenge was not accepted, but some of his theses were denounced to Pope Innocent VIII. as heretical; and though he ultimately proved their orthodoxy, he suffered much persecution. These trials induced him to give up the study of profane literature and to devote his attention to religion and philosophy. Resigning his principal in favor of his nephew, he lived at Florence until his death, a year before which Pope Alexander VI. absolved him of all heresy.

A collective edition of his works was published at Bologna in 1496, Venice in 1498, Strasbourg in 1504, and Basel in 1557-1601.

MIRIEL, Charles François Brisson de, a French naturalist, born in Paris, March 27, 1776, died near there, Sept. 12, 1854. In 1794 he entered the topographical bureau, but in 1796 fled to the south of France for political reasons. He studied botany at Tarbes under Ramond, and made several botanical tours across the Pyrenees. In 1798 he returned to Paris, and became connected with the museum of natural history. He published some essays in the Bulletin de la société phylomathique, and in 1800 began a course of botanical lectures at the Atheneum. In 1803 he became superintendent of the gardens and conservatories of Malmaison. In 1806 he went to Holland, where Louis Bonaparte appointed him his private secretary and counsellor of state. He soon returned to Paris, and in 1808 became a member of the institute, and assistant professor of botany and vegetable physiology to the faculty of sciences, and in 1828 professor of culture in the jardin des plantes. His works comprise Traité d'anatomie et de physiologie végétale (2 vols. 8vo, Paris, 1802); Exposition de la théorie de l'organisation végétale (8vo, Amsterdam, 1808); Éléments de physiologie végétale et de botanique (3 vols. 8vo, Paris, 1815). He also wrote 5 of the 18 volumes devoted to the history of plants in Sonnini's Cours d'histoire naturelle. His second wife, Léonie Aimée Zoë Réve, born in Cherbourg, July 26, 1756, was one of the best miniature portrait painters of her day. She died in Paris, Aug. 31, 1849.

MIRECOURT, a town of France, in the department of Vosges, on the Madon, a tributary of the Moselle, 17 m. N. W. of Epinal; pop. in 1866, 5,735. Nearly the entire male population are engaged in the manufacture of musical instruments, principally violins, guitars, and barrel organs. The town has a communal college, a tribunal of commerce, and a public library of about 7,000 volumes.

MIRES, Jules, a French speculator, born of Jewish parentage in Bordeaux, Dec. 9, 1809, died near Marseilles, June 6, 1871. He settled in Paris as a broker, and became director of a gas company. In conjunction with his townsman Moïse Millau, also a Jew, he purchased in 1848 the Journal des Chemins de Fér, which gave them considerable control over railway enterprise; and they increased their influence by purchasing an interest in the Conseiller du Peuple, the Constitutionnel, and other journals. They next founded the railway bank (la caisse des chemins de fer), by which they made several millions. Mires remained the sole director of this establishment in 1853, and thenceforward was prominent in many loans and industrial enterprises. In 1860 he negotiated a Turkish loan. In February, 1861, he was arrested for maladministration, and sentenced to five years' imprisonment and a fine of 5,000 francs. The imperial tribunal confirmed the sentence, but the court of cassation set it aside and ordered a new trial at Donai, which ended in a reversal of the judgment, and his escaping with one month's imprisonment for an incidental misdemeanor. But when the case was again brought before the court of cassation, the Donai decision was reversed, and Mirés served out his term of imprisonment till 1866. On gaining his liberty, he came forward as a negotiator of loans, and attempted to reorganize his bank; but the bank of France declined to deal with him, he recovered his influence among his old followers. In 1869 he was involved in a libel suit with Pèreire, and in 1870 he was sentenced to six months' imprisonment and 3,000 francs fine for attacking his former judges in his pamphlet Un crime judiciaire.

MIRIAM, the sister of Moses, the Hebrew lawgiver. She was present on the bank of the Nile, watching the fate of the infant child Moses, when he was found by the daughter of Pharaoh, and she called her mother Jochebed, the wife of Amram, to nurse him for
MIRROR

The princess. In the Bible she is called "the prophetess;" and after the passage of the Red sea she headed the triumphal procession of women, and led their song of victory. Having together with Aaron spoken against Moses in the desert, on account of his having married an Ethiopian (Cushite) woman, she was struck with leprosy, and was excluded from the camp seven days. According to Josephus, she was the wife of Hur, and grandmother of Bezauleel, the architect of the tabernacle. Her name is the Hebrew form of Mary, and the Arabic traditions confound her with the Virgin Mary. She died in Kadesh.

MIRROR (Fr. miroir, from Lat. mirari, to wonder, admire), a looking glass or speculum; any bright surface that reflects the rays of light falling upon it. The surface of smooth water is a natural mirror, which the ancient poets sometimes refer to as having been used by persons for viewing their own forms. Metallic mirrors are mentioned in Exod. xxxviii, 8, and Job xxxvii. 18. With the ancient Egyptians one of the principal articles of the toilet was the mirror. Wilkinson says it was of mixed metal, chiefly copper, carefully wrought and highly polished. It was circular, and had an elaborately ornamented handle, the designs of which were sometimes beautiful female figures, and sometimes hideous monsters, whose ugliness contrasted most strongly with the features reflected by its polished surface. The practice of using polished basins for mirrors is alluded to by Artemidorus; and the ancients also had drinking vessels, as mentioned by Pliny, the inside of which was so cut and polished that the image of one drinking from them was reflected many times. The composition of some of the ancient mirrors has been found by William Francis to have been: copper 67.12, tin 24.75, and lead 8.13 parts in 100; and by Klaproth: copper 82, tin 22, and lead 6 per cent. Their manufacture appears to have been more extensively carried on at Brandenstein. Pliny gives to Pasiteles, a native of S. Italy and contemporary of Pompey, the credit of introducing mirrors of silver. They are spoken of by Plautus, and in the time of the first emperors they became very common among the Romans, so that they were in use, according to Pliny and Sene- ca, even by maid servants, and the manufacture of them was one of the important trades of Rome. From several statements of Pliny it appears that various stones were employed as mirrors, set into the walls as panels, and otherwise used to reflect images of objects. Obsidian appears to have been most employed for this purpose. A similar stone called the stetli, and by the Spaniards gallinae, was used for the same purpose by the Aztecs, of which hard vitreous stone they also fashioned sword blades and razors. There were other stones of which they made excellent mirrors; but the description of these is too indefinite to determine their names.—Beckmann thinks that the use of the dark obsidian stone for mirrors suggested the use of glass, that this was attempted at the celebrated glass works of Sidon of which Pliny makes mention, and that they were first made of black glass, and afterward of glass covered on the back with black foil. But from the time of Pliny no certain reference is again found to glass mirrors until the 13th century. In the treatise on optics of Alhazen, the Arabian, of about the year 1000, mention is made of mirrors of iron (steel) and also of silver, but not of glass; and the same thing is remarked of the "Optics" of Vitello, of about the middle of the 15th century. But in the treatise on optics of John Peckham, an English Franciscan monk, who taught at Oxford, Paris, and Rome, and died in 1292, mirrors of iron, steel, and polished marble are spoken of, and also of glass covered on the back with lead. After this time various writers allude to mirrors of this sort, and describe their being made by pouring melted lead over the hot glass plates. In the 14th century glass mirrors were extremely rare in France, while metallic ones were in common use. Beckmann describes the following method of preparing small convex glass mirrors as common in Germany in the beginning of the 16th century: A hollow ball of glass being blown, while it was still hot a metallic mixture of lead or tin and antimony, with a little resin or salt of tartar, was introduced into it, and coated its inner surface, the resin or salt aiding the fusion of the metal and preventing its oxidation. The glass, being entirely coated within, and having become cool, was cut into small round mirrors. It is not many years since they were sold in Germany by the name of Oechsenaugen, ox eyes. They were set in a round painted board, and had a very broad border, and reflected a diminished but very clear image. The coating of glass with an amalgam of tin foil and mercury was practised by the Venetians in the 16th century. The process, as described by Porta, who witnessed it at Murano, consisted in spreading the tin foil smoothly upon a plane surface, and pouring upon it mercury, which was rubbed in with the hand or a hare's foot. The amalgam thus formed was then covered with a sheet of paper, and the glass being laid upon this and pressed down, the paper was drawn out. Weights were then laid upon the glass, and it was left for some time for the excess of mercury to drain off. The introduction of this manufacture into France is noticed in the article Glass. The chief modern improvement in the art consists in the use of very large plates, the process of coating them not differing essentially from that of the Venetians 300 years ago. The present method is as follows: A large stone table, ground perfectly smooth, is so arranged as to be easily canted a little on one side by means of a screw set beneath it. Around the edges of the table is a groove, in which mercury may
flow and drop from one corner into bowls. The table is first made perfectly horizontal, and then tin foil is carefully laid over it, covering a greater space than the glass to be coated. A strip of glass is placed along each of three sides of the foil to prevent the mercury from flowing off. The metal is then poured from ladles upon the foil till it is nearly a quarter of an inch deep, and its tendency to flow is checked by its affinity for the tin foil and the mechanical attraction of the slips of glass. The plate of glass, cleaned with special care, is dexterously slid on from the open side, and its advancing edge is kept in the mercury, so that no air or floating oxide of the metal or other impurities can get between the glass and the clean surface of the mercury. When exactly in its place, it is held till one edge of the table has been elevated 10° or 12° and the superfluous mercury has run off. Heavy weights are placed on the glass, and it is left for several hours. It is then turned over and placed upon a frame, the side covered with the amalgam, which adheres to it, being uppermost. In this position the amalgam becomes hard, and the plate can then be set on edge; but for several weeks it is necessary to guard against turning it over, as until the amalgam is thoroughly dried the coating is easily injured.—Several serious difficulties attend this process. The health of the workmen is so affected by the fumes of the mercury that they can rarely follow the business more than a few years; for this no remedy has been found so effectual as thorough ventilation and the frequent use of sulphur baths. The glass plates are liable to be broken by the weights placed upon them; and the coating of amalgam is frequently spoiled by the drops of mercury removing portions of it as they trickle down, or by its crystallizing, or by mechanical abrasion. Many methods of silivering have been contrived and patented with the view of obviating these defects, some of which are important. In 1855 a patent was granted in England to Tony Petitjean for a method of precipitating silver, gold, or platinum upon glass, so as to form a coating upon it, by the use of two solutions, the effect of which when mixed upon the glass is to decompose each other. The solutions he employed were different compounds of ammonio-nitrate of silver, tartaric acid, and distilled water; and they were placed upon the plate while this was at the temperature of 150° F. The precipitated silver within 20 minutes covered the glass, to which it adhered; and the solution being then turned off, all that remained to complete the mirror was to wash the surface, and when dry cover it with a coat of varnish to protect it from injury. The silversing thus obtained is not so white, and is rarely so free from blemishes, as the amalgam coating. In 1849 Mr. Drayton made known a similar method, an improvement upon a process which he patented in 1843. He employed ammoniaco-

1 oz., nitrate of silver 2 oz., water 3 oz., and alcohol 3 oz.; these, being carefully mixed, were all allowed to stand a few hours, when to each ounce of the liquid was added an ounce of saccharine matter, as of grape sugar, dissolved in equal portions of spirit and water. Liebig invented a method of coating glass with silver, in which, after the silver coating is laid on, it is covered with a coating of copper precipitated upon it by the galvanic current, or is protected by varnish. Silver mirrors are now extensively made in New York. For platining glass, R. Böttger recommends the following process: Pour rosemary oil upon the dry chloride of platinum in a porcelain dish, and knead it well until all parts are moistened; then rub this up with five times its weight of lavender oil, and leave the liquid a short time to clarify. The objects to be platining are to be thinly coated with the preparation and afterward heated for a few minutes in a muffe or over a Bunsen burner. The brilliancy of aluminium has caused the suggestion of its application to the coating of mirrors; but no successful experiments have yet been made with it for this purpose. Large mirrors are made in the United States by coating the imported plates. The old amalgamation method with tin foil and mercury is preferred to any of the more recent inventions, by reason of the greater whiteness and brilliancy of the reflection and the greater permanence of the coating.—For telescopes, philosophical instruments, and lighthouses, various sorts of mirrors are in use, and reference to them may be found under various heads in this work, as BURNING GLASS, FRESNEL, LIGHTHOUSE, OPTICS, SPECULUM, TELESCOPE, &c. Concave mirrors serve to concentrare the rays of the sun in one point and produce intense heat.

MIRZAPORE, a town of British India, in the province and 50 m. E. S. E. of the city of Allahabad, and 30 m. W. by S. of Benares, on the right bank of the Ganges; pop. about 80,000. It is the capital of a district containing more than 800,000 inhabitants, is the principal cotton market of the province, and is noted for carpet and cotton manufactures. The town contains fine European residences and many Hindoo temples, the latter mostly situated on the bank of the river. It is of comparatively modern origin.

MISDEMEANOR. Offences less than treason are, in law, divided into felonies (see Felony) and misdemeanors. Any crime less than a felony is a misdemeanor. Statutes sometimes declare that the offences which they contemplate shall be punishable as misdemeanors, but the term applies equally to all those crimes, whether of commission or omission, for which the law has not provided a name. Misdemeanors are either those which exist at common law, mala in se, or they are those which are created by statute, mala prohibita. Under the former class, whatever, in the language of Blackstone, mischievously affects the person...
or property of another, openly outrages decency, disturbs public order, is injurious to the public morals, or is a corrupt breach of official duty, is indictable as a misdemeanor at common law. Thus it has been held to be an indictable misdemeanor at common law to drive a carriage along the crowded street so as to endanger the lives of foot passengers; to go armed with dangerous and unusual weapons; to disturb a town meeting or a congregation engaged in religious worship. It is an indictable nuisance and scandal to the community to disinter a dead body without lawful authority; to throw a corpse into a river without the rites of Christian burial; to sell knowingly unwholesome provisions; to be guilty of notorious lewdness or drunkenness; to indulge publicly in profane swearing and blasphemy; or, as some authorities hold, to let a house knowing that it is to be used for the purpose of prostitution. So it has been held to be a misdemeanor, indictable at common law, to deposit more than one vote upon a single ballot; to kill a tree standing upon public ground; to treat an animal with wanton cruelty; to send threatening letters; or to give a challenge to fight.—Misdemeanors which are created by statute are of two kinds. The one kind embraces those which consist in the omission or commission of an act enjoined or forbidden by the statute, though the transgression be not specially made the subject of indictment. For when a statute prohibits a matter of public grievance or commands a matter of public convenience, all infractions of its provisions are indictable, unless this mode of proceeding be positively excluded; because the doing what competent authority forbids, or not doing what it requires, is itself an offence at common law. The second kind includes those statutory offences which are made specially indictable. If the punishment is expressly defined, the provision of the statute must be strictly followed. If the statute merely attaches a new penalty to what was already a common law offence, the remedy may be pursued either as at common law or under the statute.—In respect to misdemeanors, the distinction between principals of the first and second degree is unknown; and those who in treasons and felonies would be accessories after the fact, are themselves liable for the commission of a distinct misdemeanor. The ordinary punishment of misdemeanor at common law is fine and imprisonment, or either of them, in the discretion of the court; and these are regularly inflicted when no other penalty is prescribed. In Connecticut it has been decided that the fine must be less than the whole value of a man's property, and that the imprisonment must be for a less term than the whole of his life. Finally, in all sentences for misdemeanor, the court may require the defendant to give bonds to keep the peace. It is inconsistent with the general policy of the law to allow a criminal charge to be referred to arbitration or to any other mode of private settlement. An agreement to compound a felony has always been held entirely illegal and void. Properly speaking, indeed, the injured party has nothing to compromise. A crime, whatever be the degree of its criminality, is committed against the public order, and it is therefore only upon a public prosecution that the matter can be disposed of. Yet in the slighter offences against the public peace, a compromise, it is said, may be valid. Quoting from Mr. Chitty's notes to the English statutes of arbitration, Mr. Justice Puttice said in an English case, that such penal offences as assault, libel, nuisance, and the like, for which an action of damages would lie, may be submitted to arbitration at common law; and although an indictment has already been preferred, the matter of complaint may still be referred by leave of court. Plainly nothing can prevent an injured individual from submitting to arbitration the private wrong which may be measured and compensated by damages. But the public wrong done, in the slighter misdemeanors even, cannot in strictness be removed from public cognizance except by consent of the proper authority. Hence it seems to be the common law doctrine that though, in such misdemeanors as those just referred to, where the public interest is but little concerned, the criminal process will be waived almost as matter of course upon acknowledgment of private satisfaction, yet express or implied consent of the court to the waiver is still essential to the valid compromise of the matter. This doctrine of the common law is carried out in those statutes by which in several states it is provided, that upon a criminal charge of assault and battery or other minor crimes, for which a remedy by civil action is given, if the injured party appear before a magistrate and acknowledge that he has received satisfaction, the accused may, or in some cases shall, be discharged on payment of costs.

MISERERE (Lat., have mercy), the name applied in the Roman Catholic church to the 51st psalm, which commences in the Vulgate with that word, and is employed as a penitential hymn at all times, but particularly during Lent. At the end of the office of Tenebrae on Wednesday, Thursday, and Friday of Holy Week, the cherubim or seraphs recite it kneeling. At Rome, on Good Friday evening, the Misericere, set to music by Allegri, is sung with great solemnity in the Sistine chapel. Many other eminent composers have also set it to music.

MISHNAH, or Mishna (late Heb., study), the earlier part or text of the Talmud, forming a compendium of decisions, based on oral traditions, respecting the laws and religious rites of the Jews, and first systematically arranged by the patriarch Rabbi Judah the Holy and his school, toward the close of the 2d, or according to others in the first half of the 3d century. It is written in Hebrew, and divided into six
principal parts and 63 treatises. Of the former, the 1st treats chiefly of prayers and the duties of husbandmen; the 2d, festivals; the 3d, marriage relations; the 4th, judicial subjects; the 5th, matters concerning the temple; and the 6th, the institutions respecting purification. For a full analysis of the contents of the Mishnah, see Herzog's *Real Encyklpädie*, article *Thalmod*, which also contains an extract from the Talmud, showing the relation of the Mishnah text to the commentaries (Genera) of the early rabbis. Among the numerous separate editions of the Mishnah are those by Surenhusis (6 vols. fol., Amsterdam, 1698-1708, translation and notes in Latin), and by Heinemann and others (6 vols. 4to, Berlin, 1851-4, with punctuated text, German translation in Hebrew characters, rabbinical commentaries, and brief explanations). A free translation in German, with occasional paraphrase and explanatory notes, was published by Rabe (3 vols. 4to, Onolzbach, 1760-69). De Solis and Raphael published an English translation of 18 treatises (London, 1843), and Geiger a valuable *Lurh- und Lesebuch zur Sprache der Mischna* (Breslau, 1843).—The Mishnah is a very important aid in the critical study of the New Testament, illustrating many allusions to Jewish usages. But in Christian Europe this body of Jewish learning, of priceless value to Christianity as well as Judaism, narrowly escaped destruction from the fanatical violence of ignorant zealots. Only a few manuscripts copies remain. See *Hebrews*, vol. viii., pp. 504-5, and Talmud.*

**MISKOLCZ**, a town of Hungary, capital of the county of Borsod, near the Szajö, and on the railway from Pesth to Kaschan, 90 m. N. E. of Pesth; pop. in 1870, 21,199. It is situated at the foot of a vine-clad mountain called Asas. It is well built, and has five churches, a convent, a synagogue, three gymnasia, a large county house, a theatre, and a fine hospital. The inhabitants, consisting of Magyars, who are the majority, Rascians, Slovaks, Germans, and Jews, are actively engaged in trade and manufactures; the wine trade is important. A large part of the town was destroyed by fire in 1843.

**MISSIA.** See Missen.

**MISSISSAGAS**, an Algonquin tribe originally found, in the middle of the 17th century, at the mouth of a river of the same name north of Lake Huron. After the destruction of the Hurons they fled inland, and then moved to Kowecan on Lake Superior, but returned before 1670 to their old ground. Missions were then attempted among them, but they were strongly attached to their superstitions and to polygamy. They took part in the assassination of the Sioux deputies at Sault Ste. Marie in 1673, which drew on the western Algonquins the fury of that nation. About 1700 they began to treat with the Five Nations, and to move eastward, so that by 1718 they were scattered along the northern line of the lakes from their old home to the Thousand Islands, most of them being north of Lake Ontario. When the struggle between France and England began, they were the only Canadian tribe whom the English won over through the Six Nations, who adopted them as a seventh nation in 1746. They aided the English in arms, and traded at Oswego; but the English neglected them, and when war again broke out the Mississagass showed little inclination to join them. The mass of the nation were again secured by the French. After the fall of the French power they made a treaty with Col. Bradstreet, but took an active part in Pontiac's war. They were also active in the Miami war against the United States in 1792-3, and in the hostile movements of the Six Nations in the war of 1812. Their only settlement in the United States was a temporary one at Erie; they are now in the province of Ontario, Dominion of Canada. Missions have been established among them since 1824 by the Methodists and the New England company, and they are improving. They comprise the Mississagass of Mud, Rice, and Sengog lakes, returned in 1869 at 315, and in 1873 at 305. The Rice Lake Indians sold most of their lands in 1818 for an annuity of £470. Those on Sengog lake reside on 600 acres bought by them in 1843. All these bands cultivate the soil and have comfortable houses and chapels. In 1873 the Mississagass at Alnwick numbered 205; they formerly roamed destitute around Quinte bay. The Mississagass of Credit island removed to the Grand, numbered 215 in 1878. They embraced Christianity and began to improve in 1824 under the exertions of the Rev. Peter Jones, a half-breed.

**MISSAL (Lat. missale),** the mass book of the Roman Catholic church, containing the daily eucharistic service for the whole year. During the first eight centuries the parts to be recited or sung by the bishop or priest, the deacon, subdeacon, and choir, were arranged in separate volumes. The lectionary or epistolary, contained what immediately related to the consecration of the eucharist (the sacrament by preeminence), such as the canon, with the prefaces and collects; the evangelary or deacon's book contained either one of the four gospels, or all four in a volume, or only the passages selected and arranged for daily mass; the lectionary or epistolary contained the lessons from the other portions of the Bible which were sung by the subdeacon; in the antiphonary or gradual were found the anthems, psalms, and hymns chanted by the choir throughout the service; and in the benedictional were the solemn forms of benediction pronounced over the people before communion on the great festivals. St. Jerome, by order of Pope Damasus, collected the four gospels into one volume, with tables indicating the passages for daily use. The deacon's and subdeacon's books soon contained respectively only the tabulated gospels and lessons of the daily mass. The evangelary in particular was often splendidly illu-
and its rich cover was adorned with precious stones. The most ancient known is that of Verceil, said to have been entirely written by St. Eusebius, bishop of that city (died about 370).—In the 9th century (see Liber crypt) all these separate parts were united in one volume, called plenary missal, the use of which was made obligatory in all churches. The evangelist, lectionary, and antiphonary have been continued in separate volumes, for the convenience of the inferior ministers and the choir. The Roman missal consists of three principal parts: 1, the *Proprium Missarum de Tempore*, containing the formularies for the masses of the Sundays; 2, the *Proprium Missarum de Sanctis*, containing special formularies of mass for the festivals of several saints; 3, the *Commune Sanctorum*, containing general formularies for classes of saints (as apostles, martyrs, confessors, &e.), serving as an appendix to the second part for such saints as have no special service assigned them. The *Ordo Missae*, containing that part of the mass which is invariable, is inserted in the first part of the missal between Saturday of Passion week and Easter. (Concerning the Ambrosian, Mozarabic, and Gallican missals, see Liber crypt.) Some dioceses and religious orders have, in an appendix, special formularies for the masses of certain favorite saints; but the congregation of rites, to which belongs the direction of liturgical matters, disannounces everything that tends to lessen uniformity.—See the Rev. Daniel Rock, *Hierurgia* (2 vols., London, 1833; 2d ed., 1 vol., 1851), and "The Church of our Fathers, as seen in St. Osmond’s Rite for the Cathedral of Salisbury" (3 vols., London, 1849).

**MISSAUKEE**. a N. central county of the S. peninsula of Michigan, watered by the Manistee and Muskegon rivers; area, 576 sq. m.; pop. in 1870, 130. The surface is rolling and well timbered, and the soil moderately fertile. Capital, Falmouth.

**MISSINIPPI RIVER.** See ChurcHILL.

**MISSIONS, Foreign.** In a theological sense, this term denotes the efforts made by the professors of a religious creed to propagate their doctrines in countries following other religious persuasions. The disciples of Christ received from their master the command: "Go ye into all the world, and preach the gospel to every creature." In compliance with this call, the apostolic church at once began missionary operations on a larger scale than the world had ever seen before. Unfortunately the records of this first brilliant period of the missionary history of the church have been mostly lost; but enough has been preserved to show that the doctrines of Christianity were taught by the apostles themselves and their disciples far beyond the confines of the Roman empire. Toward the close of the 1st century the heroic missionary efforts of the church had called into existence numerous and flourishing congregations in the towns of Asia Minor, Greece, Italy, the islands of the Mediterranean, northern Africa, India, and probably several other countries. In the 2d and 3d centuries we see the missionaries successful in parts of southern Germany, Gaul, Arabia, and Ethiopia. Under Constantine Christianity became the state church, and the custom was gradually introduced of using coercive measures for the advancement of the Christian doctrines. The missionary zeal seems not to have abated, but it is frequently difficult for the historian to determine what share the missions and what the secular arm had severally in completing the Christianization of the various countries constituting the Roman empire. At the death of St. Patrick in the latter part of the 5th century Ireland possessed numerous flourishing churches and monastic schools, which became during the next two centuries nurseries of missionaries for Great Britain and continental Europe. Thus from Iona Columba and his companions evangelized Scotland, and his successors sent missionaries and monks to the Hebrides, the Orkneys, and Iceland; while Columbanus and his followers planted monasteries and schools in Gaul, Switzerland, northern Germany, and Lombardy. England, too, as soon as she had been restored to the faith by Augustine, sent missionaries to Germany, to which the Irish Boniface gave nature. After him another great Englishman, Alcuin, guided and encouraged in the same direction Liudger and Willehad, who preached successfully to the Saxons and Frisians, and Arno, who was equally successful among the Huns. Under Louis le Débonnaire these missionary efforts were kept up by the schools founded by Boniface at Útrecht and elsewhere. The first seeds of Christianity were then sown in Jutland, the Danish islands, Sweden, and Norway, by Archbishop Ebbo, Anscarius, and others. In the East, Iberia, Armenia, and Persia were the missionary fields. After the separation of the eastern church from the western, the interest in the missionary cause almost wholly ceased in the former. The progress of Christianity eastward was arrested, while a considerable portion of its own territory was taken possession of by the Mohammedans. The Nestorians continued for a long time to carry on, especially in China and India, successful missionary operations, of which little is now known. The Latin church continued her spiritual conquests in northern Europe. The Scandinavian kingdoms were finally gained over one after another in the 10th and 11th centuries. Cyril and Methodius opened for Christianity the way to the great Slavic race, by preaching to the Khazars, Bulgarians, and Moravians. Adalbert, bishop of Prague, was martyred in a mission among the Prussians. From Iceland, missionaries accompanied the adventurous Norsemen on their expeditions of discovery; and Greenland is believed to have received from them the first account of Christianity and the first foundation of a Christian church. The extension of Christianity in northern Europe was in some instances procured by
means which churchmen themselves disavowed and condemned. Thus Alcuin openly censured Charlemagne for the oppressive measures by which that emperor compelled the pagan Saxons to receive baptism. This habitual interference of the eastern and western emperors, while it injured the cause it was designed to serve, did not prevent zealous missionaries in every country from risking their lives in preaching to the heathen. The further treatment of the subject may be more conveniently divided under two heads. I. ROMAN CATHOLIC MISSIONS. A new missionary zeal awoke in the Roman Catholic church after the foundation of the mendicant orders, which endeavored to excel each other in extending the territory of their church. Innocent IV. in 1245, and St. Louis in 1248, sent mendicant friars as missionaries among the Mongols; and in 1299 John de Monte Corvino translated the New Testament and Psalms into the Tartar language. Several bishops were appointed for China, where the mission assumed large dimensions, but half a century later it was nearly exterminated. Toward the close of the 14th century the Franciscans supported a flourishing mission in northern Persia, with about 10,000 adherents. The missionaries to the East did not confine their labors to the pagans, but also endeavored to bring about a union of the eastern episcopal denominations, and were partly successful in the case of the Greeks, Armenians, Copts, and others. In the 15th century Portuguese missionaries settled in the islands discovered by their countrymen, and with the aid of the secular arm soon effected the nominal Christianization of Porto Santo and Madeira (1418–19), of the Azores (1432–57), and of several districts along the African coast (1480–97). Very extensive new fields for missions were opened by the discovery of America in 1492, and the circumnavigation of the cape of Good Hope in 1497. Great numbers of missionaries volunteered to be sent to the newly discovered countries, and in the East as well as West Indies missionary operations were commenced on a very large scale. In the East Indies the bishopric of Goa was established in 1520 under Franciscan missionaries, several other bishops for the East were appointed and sent out by the Portuguese government, and a large part of the Christians of St. Thomas were prevailed upon to unite with the Roman Catholic church. In Mexico and Central and South America, the 16th century completed the victory of the Roman Catholic missions, as far as the country was under the dominion of the Spaniards and the Portuguese. In many instances, however, the aid of the inquisition was invoked to suppress the pagan worship.—An extraordinary impulse to missionary labors was given by the establishment of the order of Jesuits. As shortly before a large part of Europe had separated from the Roman Catholic church, they directed their efforts equally to the conversion of the pagans and to inducing the Protestants and eastern Christians to submit again to the authority of the pope. St. Francis Xavier, who has been canonized as the apostle of the Indies and Japan, surpassed all Christian missionaries who had lived since the apostolic age in the extent of his missionary travels, and in the number of converts whom he baptized. At the time of his death about 100 Jesuits were laboring in the East Indies. Soon after, the east of Asia presented the brightest prospects. But it is particularly in Spanish and Portuguese America that the Jesuit missionaries found a fruitful field. Their first "missions" or Christian parishes along the Paraná and the Uruguay were again and again destroyed by the Mamelucos, who only aimed at reducing the natives to slavery. But having obtained from the home government official decrees declaring the Indian converts to be free men and forbidding the European settlers to molest or hold intercourse with them, a native Christian population of between 100,000 and 200,000 were united under the missionaries, taught the art of agriculture, and governed peacefully for a period of 80 years. A similar result was reached in the mining districts of Peru; while Jesuits, Franciscans, and Dominicans vied with each other in civilizing the wild tribes on the eastern slopes of the Andes and along the head waters and affluents of the Amazon. In New Granada the missionaries were no less active both among the native populations and the numerous African slaves; the most conspicuous among them was the Jesuit Pietro Claver, called "the apostle of Cartagena," who is said to have instructed and baptized upward of 200,000 negro slaves. Prescott, in his "Conquest of Mexico," recounts the enlightened efforts of Cortes to obtain efficient missionaries for the natives. The Augustinians, Franciscans, and Dominicans responded to his call, and did much to civilize and protect the indigenous tribes, while establishing everywhere schools and colleges. Later the labors of the Jesuits in California and New Mexico were attended with the same success as in South America, and their missions were ruined in the last century by the same causes. The Philippines became a Catholic country under the rule of Philip II., and even in the mighty empire of Japan the conversion of a number of princes promised the speedy victory of Christianity, when internal wars and dread of foreign rule put an end (after 1587) a bloody persecution, which ended in the second half of the 17th century in what was thought to be the complete extirpation of Christianity. In China, several Jesuits, especially Ricci and Schall, obtained great influence at the court by means of their astronomical and mathematical knowledge, and among the educated classes of the people by the classic works which they composed in the Chinese language; and this extensive influence was used with great success in gaining converts for their creed. While Spanish missionaries from Mexico were press-
ing northward, the French in 1608 began to send missionaries to North America, and established prosperous settlements among the Abenakis, Hurons, Iroquois, and other Indian tribes. Biard, Brebeuf, LaLemant, and Sébastien Rasle were the most celebrated among those who devoted their whole lives to thoroughly organizing the colonies of native Christians. The French missions gradually advanced up the St. Lawrence and along the lakes. In Abyssinia repeated efforts were made from 1650 to 1684, mostly by Jesuits, to bring the national church, which had been isolated from the rest of the Christian world for more than 1,000 years, into an organic connection with the Roman Catholic church. Several princes entered into their views, and a member of the Jesuit order was appointed patriarch; but at length a successful insurrection thwarted the project. Several other portions of Africa received Catholic missionaries in the course of the 17th century, as Morocco (1630) and Madagascar (1648), but without permanent success.

In the 18th century the Jesuit missions in the East greatly declined. In China and India they were involved in a controversy with the Dominicans respecting certain accommodations to native customs, which the Jesuits regarded as lawful, while the Dominicans stigmatized them as idolatrous. Rome then gave against the Jesuits a decision which has since been cancelled; and from that time the prosperity of their missions declined. In China, moreover, a fierce persecution broke out, which between 1722 and 1754 diminished the number of Christians from 800,000 to 100,000. In Thibet, the Capuchins tried to establish missions, but with only slight success. A larger number of conversions were made in Indo-China, especially in Cochin China and Tonquin, and the Catholic population gradually rose to several hundred thousand, mostly attended by native priests. A firm foundation, amid the continuance of persecution, was also laid in Corea. In Africa a third attempt was made (1750-54) to unite the Abyssinian church with Rome, but without success. The Portuguese missions on the W. coast of Africa almost entirely decayed. In the Spanish and Portuguese possessions of America the progress of the missions among the Indians was completely arrested by the expulsion of the Jesuits, and the attitude which the governments of Spain and Portugal assumed toward the Roman Catholic church. The French revolution greatly diminished the power and resources of the Roman Catholic church, in consequence of which nearly all the foreign missions declined, while some were given up entirely. Since 1814 the operations in the various missionary fields have again been taken up with renewed zeal; the number of missionary bishops and priests has been greatly increased, but no extraordinary success has as yet been announced. In China proper, in Corea, and in India, the Catholic population has, however, considerably risen.

Cochin China and Tongquin enjoyed likewise for some time a season of great prosperity, until, about 1857, the persecution to which more or less the Christians were generally exposed assumed such dimensions that nearly all the priests were killed or obliged to flee, and nearly every congregation was scattered. This led in 1858 to an intervention of the French and Spaniards, which terminated in 1862 in the cession to France of three provinces, and in stipulations guaranteeing the free exercise of the Christian religion. Nevertheless the persecution broke out more fiercely than ever in 1868, and four Christian parishes with about 10,000 converts have been blotted out. Japan was reopened to Catholic missionaries in consequence of the treaties of 1858, and was at once occupied as a mission field. In the summer of 1868 a most cruel persecution was begun against the native Christians, especially at Nagasaki and vicinity. The imperial decree recited that the rigorous measures pursued in the 17th century against the Christian religion had not entirely extirpated it, and that of late the number of Christians had considerably increased. Consequently 4,100 persons were taken away from their homes and distributed among 34 daimios, who were to isolate them from their fellow citizens and employ them in the most rigorous penal servitude. The several consuls at Nagasaki and the ministers resident at Tokio protested in vain against the merciless acts of the government. In 1873 the representatives of the Christian powers obtained a promise that the persecution should cease; but 660 persons had in the interval perished in prison. The whole number of native Catholics in Japan was variously estimated in 1873 at from 18,000 to 24,000, with two resident Roman Catholic bishops. The missions in Turkey, and more particularly those among the eastern churches, were in recent times greatly enlarged, and considerable numbers of Armenians, Jacobites, and Nestorians entered into union with Rome. The same step was taken in 1859 by the king of Tigre in Abyssinia, with 50,000 of his subjects. The conquest of Algeria by the French gave rise to some enterprises for the conversion of the Mohammedans, but without notable results. Special missionary associations were formed in Austria for Khartoum in Nubia, and in France for western Africa; but the majority of missionaries were swept away by the deadly climate soon after their arrival at the missionary stations. In North America, the labors among the Indians were taken up again, especially by the Jesuits and Oblates, and the missionaries advanced up to the northernmost settlements in the British possessions. In South America the Jesuits have made repeated attempts at reentering the fields of their former missionary labors along the Parana, the Amazon, and their affluents; but their efforts, being looked upon with disfavor by the local authorities, have had but a partial success. In Australasia numerous congregations
Of natives have been formed, especially in New Zealand; several smaller islands, as Wallis and Futuna, have been wholly gained for the Roman Catholic church; and, under the patronage of the French, a firm footing has been obtained in some islands which had been pre-occupied by Protestant missionaries, as Tahiti and the Hawaiian islands.—The Roman Catholic church has a number of institutions for the training of missionaries. The oldest and most celebrated among them is the propaganda in Rome. (See PROPAGANDA.) Other institutions of this kind are Greek, German, English, Irish, Scotch, Belgian, and South American colleges at Rome, and the Chinese college in Naples, founded in the first half of the 18th century by an Italian missionary in China. All the pupils are natives of China, who, after being ordained as priests, return to their country as missionaries. At Verona is a seminary which educates priests for the missions of central Africa; and in connection with this the “African Institute” of Alexandria trains native missionaries. The Greek seminary at Palermo educates priests for the United Greeks. The American college at Rome, for the training of missionary priests for the United States, was opened by Pius IX. in 1859. The seminary of foreign missions at Paris is probably the most fruitful nursery of Roman Catholic missionaries; it supplies a number of the missionary dioceses in China and Indo-China. The college of Old Hallows, near Dublin, Ireland, is of growing importance. The number of its pupils amounts to about 200. It mostly trains priests for Irish emigrants to Protestant countries; but many of them are called upon to preach to the heathen also, especially those in India. Moreover, most of the religious orders educate a number of their members for foreign missions, and some of them have special houses for this purpose. A number of missionary dioceses in pagan countries are intrusted by the propaganda to the several orders, which engage to send there the necessary number of missionaries. Those most numerously represented in the foreign mission field are the Jesuits, Franciscans, Dominicans, Lazarists, the Pious society, the Marists, Capuchins, and Carmelites. There are also supported in the missions a number of seminaries for the training of a native clergy, of which that at Penang in British Asia is one of the largest.—The first general association for the support of Catholic missions was formed at Lyons, France, in 1822, under the name of the “Society for the Propagation of the Faith.” The society gradually extended over nearly all countries of the globe. Its members pledge themselves to pay one son a week. Its total receipts in 1859 amounted to 5,629,375 francs. It publishes a bi-monthly periodical, the “Annals of the Propagation of the Faith,” of which more than 200,000 copies are issued in French, German, English, Italian, Spanish, Portuguese, Dutch, Flemish, and Polish languages. The society contributes to the support of all Roman Catholic missions. An important auxiliary to this society is the “Association of the Holy Childhood of Jesus,” a children’s missionary society, founded in Paris in 1844, for baptizing and rescuing pagan children of China, and, if possible, for providing a Christian education for them. Its annual receipts amount to about 1,500,000 francs. The Leopoldine association in Austria, and the Louis association of Bavaria, support almost exclusively missions among the German emigrants in North America. The St. Mary’s association of Austria was established for the sole support of the Austrian missions in Khartoom. France has special associations for the support of the missions in western Africa, for the foundation of Christian schools in Turkish Asia, and for missions among the Mohammedans.—The principal Roman Catholic missionary fields in pagan countries at present are: China, with a bishopric in the Portuguese possessions, 22 vicariates apostolic, 3 prefectures apostolic, and a native Catholic population estimated at 700,000; Anam, said to have 7 vicariates apostolic, 53 European and 206 native priests, with 1,280,000 Christians; and India and Ceylon, which have, besides an archbishop at Goa and 3 bishops for the Portuguese possessions, 20 vicariates apostolic, and a population of 147,000, of which only a very small portion are English, Irish, French, and Portuguese Catholics, the others being natives. The Roman Catholic population of Africa live mostly in the Portuguese, French, English, and Spanish possessions. The most important missions among the pagans are carried on in and near the French possessions in Senegambia, in Natal, and in the country of the Gallas in central Africa. In Polynesia there are 7 vicariates apostolic for the native population. New Zealand is reported to have 5,000 native Roman Catholics, and the Hawaiian islands still more. The membership of the church among the Indians of North America amounts to several thousands, and is constantly increasing.—See Lockman, “Travels of the Jesuits into various parts of the World” (2 vols., London, 1762); Lettres édifiantes et curieuses (20 vols., Paris, 1780-88); W. J. Kip, “Jesuit Missions in North America” (New York, 1846); De Smet, “Oregon Missions” (1847); Huc, “Christianity in China, Tartary, and Thibet” (2 vols., London, 1853); J. G. Shea, “History of Catholic Missions among the Indian Tribes of the United States” (New York, 1855); Relations des Jésuites (3 vols., Quebec, 1838); Marshall, “History of Missions” (2 vols., London and New York); and Annales de la propagation de la foi since 1852. H. PROTESTANT MISSIONS. The reformers were not indifferent to the duty of giving the gospel to the heathen. Luther took frequent opportunity to remind the Christians of the "misery of pagans and Turks," and to exhort to prayers for them, and to the sending of missionaries to them. While the Protestant church was itself struggling for an existence,
However, the time was not auspicious for inaugurating extensive missionary operations. Yet a beginning was made in 1555. Ville-
gagnon, a knight of Malta, under the patronage of Henry II. of France, began the formation of a French colony in Brazil, and, on
the promise that the reformed religion should be taught there, 14 spiritual teachers were fur-
nished by Calvin. On landing in 1556, they
immediately set themselves to work in the or-
ganization of the future church, but their ef-
forts were soon arrested, as Villegagnon de-
manded and obtained their return to France.
Some evangelical princes showed a great in-
terest in the cause. Gustavus Vasa of Swe-
den, in whose dominion paganism still existed
among the Lapps, founded a mission in their
country, which was vigorously supported by
some of his successors, especially by Charles
IX. Many of the German princes, as Duke
Christopher of Wurttemberg and Duke Ernest
the Pious of Saxe-Gotha, made great efforts to
awaken an interest in the missionary cause.
In 1664 a German baron, Ernst von Wels,
published two pamphlets in order to awaken
a greater interest in foreign missions, and
proposed the formation of a “Jesus Associa-
tion” for the propagation of Christianity
among the pagans. But few German theolo-
gians supported him, and the majority called
him a fanatic and heretic. Wels went to Hol-
land, where he was ordained as a minister,
and then set out as a missionary to Surinam,
where he soon fell a victim to his zealous la-
bors.
About this time three Protestant na-
tions, the Dutch, English, and Danes, began
to wrest from the Spaniards and Portuguese
many of their transmarine possessions, and
thus to open to Protestant missionaries a vast
field of labor. The Dutch founded a number
of colonies in the Molucca islands, Ceylon,
and Sumatra, and displayed a great zeal in
gaining the natives for the Reformed church.
The motives and means of these missionary
efforts were not always pure; thus, the gov-
ernor of Ceylon declared that only those na-
tives would get any kind of employment from
the government who would sign the Helvetic
confession. This declaration induced thou-
sands to demand baptism, which was generally
refused to none who were able to recite the
Lord’s Prayer and the Ten Commandments.
At the close of the 17th century about 300,-
000 Cingalese had been baptized. There were,
however, many devoted missionaries, who
earnestly labored to spread a spiritual Chris-
tianity. The learned Walaeus of Leyden ad-
voated the formation of a missionary semi-
nary, and the Dutch East India company cor-
dially approved of the scheme, the execution
of which proved eminently useful to the cause
of reformed religion. — The early settlers of
New England (1620) took a deep interest in
the welfare of the pagan Indians around them.
The settlement of the country was undertaken
partly as a missionary enterprise. Indeed, this
was embodied in the Massachusetts charter, as
“the principal end of the plantation;” and the
seal of the colony had for its device the figure
of an Indian, with the words of the Macedo-
nian entreaty, “Come over and help us.” In
1646 the Massachusetts legislature passed an
act for the encouragement of Christian mis-
sions among the Indians, and in the same year
the celebrated John Eliot, “the apostle of the
Indians,” began his labors among them.
The first Bible printed in America was that which
he translated for the aborigines. A few cop-
ies of that Bible are still in existence, but no
living Indian can read it. But Eliot was not
the first to preach the gospel to the natives.
Thomas Mayhew began his labors among them
on Martha’s Vineyard in 1643, and soon num-
bered 300 converts. Five successive genera-
tions of the Mayhews continued these labors.
In 1674 the Indians of the district were about
9,000 half of them professing Christianity;
but in 1792 they numbered only 440. The
Rev. John Sergeant and Jonathan Edwards
did like missionary service among the Stock-
bridge Indians in western Massachusetts, and
David Brainerd among the Delawares of east-
er New York and New Jersey.— A vast
scheme of uniting all the Protestant churches of
the world into one great missionary society
was conceived by Cromwell. He intended to
establish a Protestant college for the defence
and propagation of the evangelical faith, which
was to consist of seven directors and four sec-
retaries, and to receive from the state a fixed
annual support. The whole earth was divided
into four missionary provinces, each of which
was to have its representative in the college.
Though this scheme was not carried through,
it prepared the English nation for an active
support of the missionary societies which soon
after sprang into existence. The formation of
the first great missionary society of the Pro-
testant world took place at the beginning of
the 18th century. Some members of a “So-
ciety for promoting Christian Knowledge,”
which had been founded in 1698, constituted
themselves in 1701 a committee for sending
missionaries to the pagans. They assumed
the name of “Society for the Propagation of
the Gospel in Foreign Parts,” and the new
association was sanctioned by William III.
The original design was the formation of colo-
nial churches, and mostly for this purpose the
operations have been extended to the East and
West Indies, southern Africa, the Seychelles,
Australia, Tasmania, and New Zealand. In
1873 it had 494 ordained missionaries, inclu-
ding 45 native clergy in India, 829 teachers and
catechists, 141 students in colleges abroad, and
an income of £110,259. It is under the con-
trol of the church of England, and the influ-
ence of the “high church” school at present
prevails in its management. The “Scottish
Society for propagating Christian Knowledge,”
founded in 1709, labored for some years among
the North American Indians, but without per-
manent success.—Denmark, though it had begun in 1620 to found colonies in the East and West Indies, made no missionary exertions in behalf of the pagans until the reign of Frederick IV., who in 1711 established an annual appropriation of 2,000 rix dollars for missionary purposes, and in 1714 organized the royal college of missions. Unable to find the proper remarkable enterprise one in Denmark, the government entered into arrangements with A. H. Francke, who furnished the first men, Ziegenbalg and Plutscho, for establishing a mission in Tranquebar. The society afterward extended their Indian missions considerably, though Denmark took very little interest in them. Most of the missionaries, among whom Christian Friedrich Schwartz shone forth as a model, came from Germany, and the expenses for the missions in the territories of the East India company were mostly defrayed by the London society for promoting Christian knowledge. In 1835 the chief missions of this body were transferred to the society for the propagation of the gospel; and in 1845, when the last Danish possessions in India were transferred to Great Britain, the labors of the college of missions there ceased altogether. The impulse given by King Frederick IV. to the missionary cause called into existence two other remarkable enterprises. The one was a mission in Greenland, commenced in 1721 by a Norwegian pastor, Hans Egede; the other a new mission to Lapland, undertaken by the Norwegian Thomas von Westen. Both were conducted with great zeal and self-sacrifice. Egede induced the king to establish at Copenhagen a seminary, which trained catechists and missionaries for the Greenlanders, until the mission was wholly committed to the Moravians. It was in Copenhagen also that Count Zinzen dorf received his first impulse toward spreading the gospel. On his return to Hernhut the Moravians engaged at once in the cause with a zeal unprecedented in the history of Protestantism. The support of foreign missions was for the first time officially declared to be a duty of the entire church, and an official board was intrusted with the charge of it. The guiding principles of the Moravians were to await a special call from God before going to any part of the pagan world, to avoid as much as possible selecting missionary fields preoccupied by others, and to give the preference to those countries which were among the most abandoned, difficult, and miserable. All the missionaries gained a part or the whole of their support by mechanical or agricultural labor; and the congregations of natives, which were all organized after the model of the church at home, were likewise bound to contribute for missionary purposes. Thus their enterprises stand forth as a great success. The fields which they occupied in succession were the Danish West India islands (1732), Greenland (1733), North American Indians (1734), Surinam (1735), South Africa (1736, renewed in 1792), Jamaica (1754), Antigua (1756), Barbados (1765), Labrador (1770), St. Kitts (1775), Tobago (1790, renewed in 1827), the Mosquito coast (1848), Australia (1849), and Thibet (1853). In 1873 they reported in all 90 stations, 522 missionary "agents," 1,427 native helpers, 21,869 communicants, and an income of £18,015. One out of every 50 of its communicants is engaged in mission work, with three times as many members in its mission churches as in those at home.—There is a great gap in the history of Protestant missions from 1792 to 1792. No new society was formed, and no efforts were made for the propagation of Christianity except by the few agencies above mentioned. Toward the close of the 18th century there arose a widespread dissatisfaction with the results of the rationalistic intellectualism of the day, and a powerful commercial interest led vast numbers back to a belief in the supreme necessity of experimental religion and personal piety. At the same time, members of different communions longed to find ways of working together for a common Christianity, in spite of denominational differences. The first foreign missionary society born of this movement was the Baptist of England, established in 1792. The effect of this example throughout Christendom was unparalleled. Other societies arose in England and America, until almost every religious denomination had its own. Money was freely given, missionaries were sent abroad, and converts from paganism were multiplied. In continental Europe the interest in the missionary cause developed more slowly, but has attained considerable proportions. Brief sketches of the most important Protestant missionary societies follow, arranged according to nationality. 1. British Societies. The Baptist society, already named, was the first, organized October 2, 1792, under the lead of William Carey, who was also its first missionary. He went to India in 1798, and Scampore soon became the centre of successful and extensive missionary operations. A controversy between the Scampore mission and the parent society brought on a separation lasting ten years, during which the two societies acted independently, but it did not arrest the progress of the mission. The Bible entire or in parts was issued from the Scampore press in 27 different versions, and the school operations were singularly prosperous. Among the missionaries, Marshman and Ward were especially distinguished. Besides India, the West Indies, western Africa, and France received missionaries from the Baptist society. In the West Indies, the churches in Jamaica separated from the home society in 1842, and charged themselves with the maintenance of the mission. In western Africa, the missionaries were expelled in 1856 by the Spanish government from the island of Fernando Po, and their missions forcibly suppressed. The society now has missions in France, Norway, Italy, western Africa, India, China, and the
West Indies, with 423 stations, 87 missionaries, 229 native pastors and preachers, 32,444 communicants, 280 teachers, 12,101 scholars, and an income of £40,255. The General or Armenian Baptists formed a separate society in 1816, and began a mission at Orissa, India, in 1822, and at Ningpo, China, in 1845. In 1873 they had 8 stations in India, 7 missionaries, 15 native preachers, 731 communicants, and an income of £14,216, much of which is raised in India where the work is done. The mission in Ningpo has ceased after a feeble existence, and one has been commenced in Rome.—The "London Missionary Society" owed its origin to a spirited paper in the "Evangelical Magazine," advocating the formation of a missionary society on the broadest possible basis. An invitation for that purpose was signed by 18 Independent, 7 Presbyterian, 3 Wesleyan, and 3 Episcopal clergymen; and the constitutive assembly took place Sept. 22, 1795, in a chapel of the countess of Huntington. The islands of the Pacific were selected as the first missionary field, and 29 young men were selected from the large number of those who had offered themselves. On March 4, 1797, the missionaries landed on Tahiti and opened the first mission of the London society. Soon the society occupied also China and the East Indies, where Morrison and Milne prepared a translation of the Bible into Chinese, the islands of the Indian archipelago and Mauritius, southern Africa, the West Indies, Guiana, and North America. Their most important stations are at present those in the South seas, where John Williams labored so nobly and successfully, in southern Africa, where Moffat and Livingstone distinguished themselves, and in Madagascar. In 1873 the society had 156 ordained missionaries, 175 native ordained ministers, 4,006 native preachers, 97,967 communicants, 2,601 schools, 72,299 pupils, and an income of £115,909, of which about £21,950 was from English and native contributions in the mission fields. The society still adheres to its original basis, avoiding denominational differences of doctrine and church government; but the subsequent organization of separate denominational societies has left the London society mostly in the hands of the Independents.—The "Church Missionary Society" was organized April 12, 1799, by distinguished men belonging to the evangelical school of the established church, among whom William Wilberforce, Charles Simeon, and others took an active part. Its progress was slow at first; no missionaries could be found for it in England, and it employed only Germans. Its first mission on the west coast of Africa was unsuccessful, in consequence of the deleterious climate and the plots of the slave traders; but after 1818 mission labors were very prosperous in Sierra Leone. In 1814 the society had stations also in India and New Zealand; in 1822 in Rupert's Land, North America; in 1826 in the West Indies; in 1844 in China; and in 1857 on the banks of the Niger. In 1873 it had 157 mission stations, 207 European missionaries, 147 native clergy, 2,278 catechists and teachers, 22,555 communicants, and 45,782 scholars, not counting 4,336 communicants and 12,866 scholars recently transferred to the native church of Sierra Leone. The income of the society for 1873 reached the extraordinary sum of £261,221, nearly £100,000 above its usual receipts. The president of the society must always be elected from among the members of parliament. Vice presidents are, according to a resolution of 1841, all the bishops of the Anglican church. Since 1825 the society has owned a missionary institute at Islington, which has room for 50 students, and generally counts about 30. The low church party of the establishment has always had a decided control over this society; yet all its missionaries have to submit to episcopal ordination and to subscribe the thirty-nine articles; even the Germans who are employed by the society are now no longer exempt from the latter condition.—The first mission of the Wesleyan Methodists was commenced in 1786, when Dr. Thomas Coke, with three other missionaries, went to the West Indies. After the death of Wesley, Coke remained at the head of the Wesleyan missions, and crossed the Atlantic for missionary purposes no fewer than 18 times. Within 20 years the number of Methodist missionaries in the West Indies and North America rose to 43. In 1813 Coke embarked with five companions for the East Indies, but died before that country was reached. His companions founded a mission in Ceylon, which soon spread to the mainland of India. As long as Coke lived, the administration of foreign missions lay almost exclusively in his hands, under the advice of a committee consisting of all the resident Wesleyan ministers of London; but after his death the necessity of a more complete organization was felt. The "Wesleyan Missionary Society" was constituted in 1817, and soon took a foremost rank among such agencies. It has missions in Italy, Spain, Portugal, Africa, India, China, Australia, Polynesia, and the West Indies. But much the larger part of this society's work is in nominally Christian lands, or in British dependencies and among English colonists. Even in Africa and India its labors are much among English-speaking people; but its most successful missions are among the negroes of the West Indies and among the heathen and cannibals of the Feejee and Friendly islands. In 1873 it had in all 847 stations, 6,647 chapels and other preaching places, 1,125 ministers and assistant missionaries, 4,783 other paid agents, 170,360 communicants, 15,616 probationers, 245,753 pupils, and an income of £167,908.—Besides these larger societies, there are a number of smaller ones, as the Welsh Calvinistic Methodist, founded in 1849; the English Presbytery, 1844; the "Turkish Missions Aid Society," and the New Connection Methodists'
The foreign mission, commenced in China in 1859. -

A "Scotch Missionary Society" was organized at Edinburgh in 1796, and sent the first missionaries among the Tartars near the Black and Caspian seas. After the suppression of all the Protestant missions in those regions by the Russian government in 1833, the association directed its efforts to western Asia and the West Indies. More recently the society has confined its labors to Jamaica. The established church of Scotland, at its general assembly of 1796, rejected as a folly a motion to send missionaries among the pagans; but in 1824 a similar motion was entertained and carried. It was not however till 1829 that its first missionary, Dr. Duff, was sent out to Calcutta. In 1843, when a large portion of the ministers and laity left the established church of Scotland, and organized the Free church, all the missionaries joined the latter. The missionary cause greatly gained by this separation, for the established church sent out new missionaries to carry on the work, and both churches henceforth tried to excel each other in zeal. The church of Scotland has four missionaries in India (one at Calcutta, one at Madras, one at Sealkote, and one at Darjeeling), and a mission at Bombay, superintended by a European teacher, and an income of £10,000. The Free church of Scotland has missions also in India, south Africa, Australia, and Syria, with 45 European and 196 native laborers, 2,168 communicants, 11,060 scholars, and an income of £19,950. It is also engaged in mission work among the Jews, having one of its important centres at Constantinople, with an imposing mission house, embracing chapel and school rooms and about 200 scholars. The United Presbyterian church of Scotland has missions in the West Indies, Spain, Old Calabar, south Africa, India, and China, with 54 stations, 188 out stations, 48 European missionaries, 8 medical missionaries, 8 native preachers, £927 communicants, 1,185 scholars, and an income of £83,000. The Presbyterian church of Ireland has 7 missionaries in India, with 138 communicants and 1,199 scholars, and one missionary in China, and an income of £3,371. - Among the other societies established by Great Britain and its colonies are: the Glasgow missionary society, in 1796; the United Seccession church’s foreign mission, 1853; the Glasgow African mission society, 1887; the Edinburgh medical missionary society, 1841; the Reformed Presbyterian church’s foreign mission, 1842; the Loo Choo naval mission, 1843; the Patagonian mission, 1844; the Chinese evangelization society, 1850; and the Chinese society for furthering the gospel, 1850. One of the most useful societies at work in India is the "Christian Vernacular Education Society," with 3 training institutions, 209 native teachers, and 7,000 children in Christian schools. The society has printed 4,000,000 copies of various publications, in 14 different languages, and has 27 depots for the sale of books with 60 colporteurs at work. There is also a "China Inland Mission," which is hardly an organized body, as it consists only of volunteers who go forth independently and with no pledge of support from any society. They are from England, mostly uneducated, and are endeavoring, as their name imports, to carry the gospel to the interior cities of China. There are 31 such laborers, male and female, with 50 native assistants, occupying 50 stations. They adopt the costume of the country, and find their living among the people, but so far their mission is not eminently successful. - The United States attention was early called to the necessity of missionary efforts among the Indians and negroes. The first general foreign missionary society was founded under the name of the "American Board of Commissioners for Foreign Missions" in 1810. It owed its origin to a society of students of Andover theological seminary, among whom was Adoniram Judson, whose object was to investigate the best ways and means of making the gospel known to pagan nations. After the model of the London society, they adopted no denominational basis; but the society soon became prominently the organ of the Congregationalists and some of the Presbyterian churches. One of the latter, the Reformed (Dutch) church, separated in 1837, and organized a denominational board, which now has three missions (one at Arcot in India, one at Amoy, China, and one at Yokohama, Japan), with 11 stations, 61 out stations, 13 missionaries, 153 other laborers, 1,323 communicants, 1,092 scholars, 3 medical dispensaries, in which 12,283 patients were treated in 1873, an income of £55,352, and an expenditure of £68,106. The "New School" branch of the Presbyterian church continued to cooperate with the American board till 1870, when, upon the reunion of the two branches of the northern Presbyterian church, most of its churches withdrew and gave their support to the Presbyterian board, taking with them, by an amicable transfer, the missions in Syria, Persia, west Africa, and that to the Seneca Indians of New York. The American board now has missions in India, China, Japan, south Africa, Turkey, Austria, Spain, Mexico, the Hawaiian islands, the Micronesian islands, and among the Indians of our own country. Its success in the Hawaiian islands has been most remarkable, the board numbering at one time more than 22,000 members in its churches. It has 19 missions, 72 stations, 497 out stations, 151 missionaries, 222 churches, 10,604 communicants (not including some 12,000 in the Hawaiian islands), 12 training schools or theological seminaries, 21 boarding schools for girls, 551 common schools, 20,490 scholars, an income of £469,000, and an expenditure (1873-4) of £482,000. - The American Baptist Missionary Union was founded in 1814, and like some others does not confine its operations to heathen lands, having missions in Germany, Sweden, France, Spain, Greece, Africa, Burmah, Assam, India, China,
and Japan; 20 missions in all, 21 central stations, 400 out stations, and 54,735 communicants in the region of Europe; income (1873-4), $261,000; expenditures, $289,309.

The missionary society of the Methodist Episcopal church was organized in 1819, and has missions in Germany, Denmark, Norway, Sweden, Italy, European Turkey, Africa, India, China, Japan, the West Indies, Mexico, and South America, with 200 missionaries, 435 assistants, 317 teachers, 14,663 communicants, 5,335 probationers, 21,242 pupils, and an income of $337,190. The Protestant Episcopal church organized a board of missions in 1820. It has missions in Greece, west Africa, China, Japan, the West Indies, and among the American Indians, with 3 missionary bishops, 17 missionaries, 33 native clergy, 22 churches, 400 communicants, 50 schools, 1,700 scholars, and an income (1873) of $114,110. The board of foreign missions of the Presbyterian church was formed in 1837, sustained by the "Old School," while the other branch still cooperated till 1870, as before mentioned, with the American board. It was preceded by a number of smaller societies, which confined their labors mainly to the Indians. Presbyterian missions were begun in Africa in 1833, in India in 1833, in China in 1838, and among the Chinese in California in 1859; and more recently the board has sent missionaries to South America, Mexico, Siam, and Japan, besides reinforcing and enlarging the missions in Syria, Persia, and Africa, which were received from the American board. It has 134 missionaries, 116 native pastors and preachers, 440 other native laborers, 6,272 communicants, 12,538 scholars, and an income (1873) of $823,000, $128,000 having been raised by special effort to pay a debt. The Presbyterian church, some years ago, established a separate board in 1861, and now has 21 missionaries and 38 assistants, laboring among our own Indians, in Mexico, South America, Italy, Greece, and China. The society reports an income (1873) of $42,431. The United Presbyterian missionary society, organized in 1859, has missions in Syria, Egypt, India, and China, 23 stations, 13 missionaries, 83 native ministers and teachers, 21 churches, 655 members, 22 schools, 2,338 scholars, and an income of $65,- 653. The Evangelical Lutheran church has sustained a mission in India since 1841, which now has 5 ordained missionaries and 40 native assistants; it has also a station in Liberia, with 3 missionaries. Its receipts in 1873 were $28,000. The Seventh Day Baptists commenced missionary operations in 1842, and have small missions in west Africa and China. The Baptist church, South, constituted a society in 1845, and has missionaries in China (4), Africa (10), Italy (6), and among the American Indians (56 native preachers and 2,500 members), with an income of $52,000. The Methodist church, South, has 4 mission- aries in China, with 3 or 4 native laborers, and 12 white preachers and 16 native ministers among the American Indians. The Freewill Baptists and the Unitarians have done something in India. Some of the free Baptist missions separated from the older organizations on the ground of their complicity with slavery, and thus the "Free Baptist Missionary Society" was organized in 1843, with a mission in Hayti; and the "American Missionary Association" was formed in 1846. In the latter three smaller organizations, the "Union Missionary Society," the "Committee for the West Indian Mission," and the "Western Evangelical Missionary Association," were soon merged, and gave it missions in the West Indies, among the North American Indians, and in western Africa. It has also had a small mission in Siam, and another in the Hawaiian islands. Since the civil war, however, its energies have been devoted to the freedmen of the south, establishing schools and colleges, furnishing teachers and professors, and aiding in forming churches. It has three missionaries in the West Indies, two in west Africa, one in Siam, and one in the Hawaiian islands. It has recently announced its purpose of relinquishing all its foreign work, except the Mendi mission in west Africa, and concentrating its efforts upon the colored people of the south, where it already has 47 churches, 2,898 members, 65 schools, 7 colleges, 323 ministers, missionaries, and teachers, and 14,048 scholars. The society has also a mission among the Chinese in California. Its income in 1873 was $345,277. The "American and Foreign Christian Union," supported by several denominations, was established in 1849 by the union of three smaller societies, and its labors have been devoted chiefly to the Roman Catholics of America and Europe, with missions in Mexico, South America, and among the zulus. But of late years the various denominations have undertaken the same work by their separate societies, and as the society was thus losing a large part of its constituency and resources, in 1873 it transferred its foreign work to other societies, and now confines its efforts to the Roman Catholics of the United States. Its receipts in 1873 were $28,571. Recently a number of ladies' missionary societies have come into existence. The first was the "Woman's Union Missionary Society," established in New York in 1851, with special reference to work among the zulus. But of late years the various denominations have undertaken the same work by their separate societies, and as the society was thus losing a large part of its constituency and resources, in 1873 it transferred its foreign work to other societies, and now confines its efforts to the Roman Catholics of the United States. Its receipts in 1873 were $28,571. Recently a number of ladies' missionary societies have come into existence. The first was the "Woman's Board of Missions," sustained chiefly by the Congregationalists and auxiliary to the American Board, was organized in 1868; it has 500 auxiliaries, and an income of $77,- 000. Similar societies have been organized in connection with the Methodist church (1869), with 1,500 auxiliaries and an income of $64,- 309; in the Presbyterian church (1871), with 376 auxiliaries and receipts of $87,316; and in the Baptist church (1871), with 600 auxilia-
ries, and receipts of $88,378,—3. Continental Europe. The continent of Europe has remained, in seal for the missionary cause, far behind England and America. The first country which, at the close of the 18th century, followed the example of the English, was Holland, which formed in 1797, mainly through the influence of Dr. Vanderkemp, a Dutch missionary employed by the London missionary society, the "Netherlands Missionsary Society," at Rotterdam. The political events, in consequence of which Holland lost her colonies, caused a postponement of independent operations till 1819, when they commenced in the Indian archipelago, which is still their chief seat. The missions in India proper, when Holland exchanged with British these settlements, were transferred to English societies, but other missions were founded at Surinam, Guiana, and in Curacao in the West Indies. The society sustains a seminary at Rotterdam, and counted among its missionaries the celebrated Dr. Gutzlaff. The most extensive of the missionary societies of continental Europe is that of Basel. Unlike the others, it was preceded by the establishment of a missionary seminary in 1815, which has furnished a number of devoted missionaries to other societies, especially English. An independent society, the "Evangelical Missionary Society of Basel," was formed in 1821, which now sustains missionaries in west Africa, India, and China. The income in 1872 was 864,167 francs. The society employs 98 European missionaries, 59 European ladies, and 210 native laborers, and has 8,718 communicants. The Basel society has received from its foundation the missionary contributions from a number of the German churches. Afterward several other societies sprang up, whose operations, however, have been thus far inferior to those of the English and American societies. Those exclusively or mainly Lutheran are the Evangelical Lutheran missionary association of Leipzig, founded in 1830, and occupying in southern India the former missionary field of the Danes, with 17 European missionaries, 18 stations, embracing 397 villages, and numerous native agents; the Berlin missionary society, instituted in 1824, and supporting a mission in southern Africa with 31 stations and 48 laborers; and the Hermannsburg society, founded in 1854, which has adopted the plan of sending out entire missionary colonies. Those whose sympathies are with the evangelical party are the Rhenish missionary society, founded in 1828, Gossner's missionary union, in 1830, and the North German missionary society, in 1836, which have missions in Africa, India, China, the Indian archipelago, and the islands of the Pacific. The Rhenish society has 11 missionaries, 18 native helpers, 9 stations, and more than 1,400 adherents, among the Batta people of Sumatra. Special associations for China have been formed in Cassel, Berlin, and Pomerania, mostly occasioned by the reports of Dr. Gutzlaff; and it was intended to unite them all into a central Chinese missionary association, but this proved unsuccessful. Of late years, the aggregate receipts of the German missionary associations have rapidly risen, as the supreme authorities of nearly all the state churches have strongly recommended them and prescribed the taking up of an annual collection in every church.—France has had a missionary society since 1822, which sustains a flourishing mission among the Bassutos of southern Africa, where it now has 17 stations, 69 native helpers, and 2,229 converts. Its total income is 13,784 francs.—The Scandinavians have been as yet hardly represented in the foreign missionary field. The Swedes have almost restricted themselves to sending preachers to the Laplanders, and only China has received a few missionaries from a society in Lund. The Norwegian missionary society, established in 1842, has some agents among the Zoolobs in southern Africa. But in Scandinavia also the activity of the missionary societies is increasing. Norway founded a foreign missionary seminary at Bergen in 1859; the second Scandinavian church diet recommended the formation of one great Scandinavian missionary society; and in Denmark, the union of all the local societies into a Danish missionary society was effected in June, 1860.—There are now 52 Protestant evangelical missionary societies engaged in giving the gospel to the unevangelized nations, with an aggregate yearly expenditure of over $65,000. In its own country has 574 Protestant missionaries in various fields, supported in their work at an expense of $1,704,000.—The Missionary Field. Having thus considered the different missionary organizations of the Protestant world, it remains to glance at the various mission fields and see what has been accomplished. We begin with Japan, with its 35,000,000 people, one of the fields most recently opened to Protestant missionary efforts. But little direct missionary labor has yet been accomplished there, and the government has not yet granted entire freedom for the proclamation of the gospel. Still, 30 Protestant missionaries, of 11 different societies, are at work, in a limited way, in a few of the coast cities. They have done something in education, and have gathered a few converts into four churches already formed, one at Kobe, one at Ozaka, one at Yokohama, and one at Tokio, the capital. It is confidently anticipated that the government will soon remove all restrictions against the preaching of the gospel. Meantime, the readiness of the government and people to adopt the western civilization is one of the wonders of the age. Robert Morrison may be regarded as the founder of Protestant missions in China. He began his labors at Canton in 1807, and in seven years gave to the Chinese a translation of the New Testament, together with a dictionary and grammar of their own language; and in eleven years he had published the entire Bible
in their own tongue, having meantime been joined in his labors by Mr. Milne, another English missionary. But the operations of Protestant missionaries were greatly circumscribed for many years by the exclusiveness of the Chinese. It was not till 1861 that the empire was really open to their labors. From 1842 to that time the residence of foreigners, for trade or other purposes, was restricted to five cities upon the coast; but now missionaries of 22 different societies, about 150 in all, are residing in various parts of the empire, with missions virtually established in 40 walled cities and 360 villages, with 100,000 adherents and 10,000 church members. A remarkable religious movement has been developed in Chimi, a district of northern China. Thousands of people were found there called the "nameless sect," repudiating idolatry, recognizing the existence of a Supreme Being, believing in a final judgment, and looking for a "deliverer." Missionaries have visited them and given them more perfect instruction, baptized many, and organized a church among them, and many of them now recognize Jesus Christ as the "deliverer" for whom they were looking. In the province of Chikiang are 1,500 native Christians, with at least 150 native ministers, catechists, and teachers. There are 12 Protestant chapels and 20 missionaries in Peking. The Bible and other religious books have been given to the Chinese in several of the different dialects of their language, together with a dictionary of the Canton dialect by Dr. Morrison, as already mentioned, of the Fokien dialect by Dr. Medhurst, and of the Mandarin by S. Wells Williams. Eight presses are in constant operation at Shanghai alone, where 12,000,000 pages a year are printed. Apart from linguistics, physics, medicine, history, geography, law, and miscellaneous subjects, have been published in China by Protestant missionaries. These works are in a style acceptable to the learned classes, and many of them have been reprinted by the Chinese themselves, and thus added to the permanent literature of the country. Conspicuous among such works is Wheaton's "International Law," translated by an American missionary and published at the expense of the government. A healthful influence has thus been exerted upon the educational interests of the country, and a demand for the western sciences has been created. An American missionary is president of the imperial university of Peking, and Chinese youth are being sent in considerable numbers to America and Europe for education. Another striking illustration of the influence of missions in China is the fact that the Chinese in some places are resorting to preaching to meet and oppose the progress of Christian truth, defending idolatry by public sermons in halls and temples. Men are selected for this service by competitive examination. The people are also resorting to works of benevolence, founding hospitals and dispensaries, distributing medicines and coffins gratuitously to the poor, and establishing free schools and lyceums. Coming westward, we find Moravian missionaries laboring on the borders of Thibet. American Presbyterians have 3 churches and 60 members in Siam. American Baptists are at work successfully in Assam, especially among the G arrows, a hill tribe, where many are accepting Christianity. European missionaries are in the islands of Sumatra, Borneo, Celebes, and the Moluccas, with encouraging prospects, but no great results yet reached.—Work was begun in Burmah by the Baptists of America in 1818, under the lead of the celebrated Adoniram Judson. Their greatest success has been among the Karens, a native tribe more accessible than the ruling classes. There are 75 Protestant missionaries laboring in that land, with 421 native preachers, 379 churches, 20,000 members, more than 60,000 adherents, and 6,000 children in schools. The king is friendly to the missionaries, and disposed to encourage his people to receive at least the western civilization. He has ordered the translation of an English cyclopedia into the Burmese tongue, that his people may have access to the treasures of knowledge, and has built a school house for 1,000 scholars, to educate the best of the young men for teachers of the people.—India is as large as all the United States of America east of the Mississippi, and inhabited by nearly 240,000,000 people, speaking a large number of languages and dialects. The first Protestant missionaries to India were from Denmark, sent to Tranquebar by the king in 1706. They were few, however, and accomplished but little. The real work for that land was begun by Carey in 1795. Since that time 33 societies have established missions in India. The American Board has labored among the Maharrattas in Bombay, Abmednugur, Seroor, Sattara, and that region, and among the Tamil people of the Madras and Madura districts and Ceylon. The church missionary and London societies have labored with great success among the Shanars, or devil worshippers, and other tribes in southern India, where they now number among the Shanars alone 90,000 adherents and 12,000 communicants. Of this region the official "Blue Book" says: "The districts are dotted over with flourishing villages and Christian churches. There are hundreds of native teachers employed among them, of whom 56 are ordained and supported to a great extent by their congregations. Order and peace rule these simple communities, which give the government little trouble; while large tracts of country have been brought under cultivation, and the peasants enjoy a larger share of material comfort than in days gone by." A great revival has recently occurred among the Syrian Christians of Malabar and Travancore, an ancient Christian sect which had lost almost all of Christianity except the name. The church missionary and London societies have long been laboring.
among them, but this revival has been promoted mainly by the preaching of native evangelists, and, though marked with some extravagances, thousands are thought to be truly converted. American Baptist missionaries are meeting with like encouragement among the Telugus in the east. In 10 years the converts have increased from 25 to 6,418. The church at Ongole had two members in 1866, and 2,587 in 1873. Like success has been realized by European missionaries among the Kols and Santals, aboriginal tribes W. and N. W. of Calcutta, 10,000 adherents having been gained among the former since 1845, and 229 added to the churches among the latter in 1872. American Presbyterians are occupying Mypoor, Futehghur, Saharanpoor, and Allahabad, principal cities to the northwest, along the valley of the Ganges. American Methodists are in Bareilly, Lucknow, and Moradabad, of the same region; and European missionaries are in almost every part of the land. Nayan Sheeshadri, the Brahman whose visit to England and America excited great interest in 1873, is establishing and superintending a chain of missionary operations through several cities and villages 300 miles N. E. of Bombay. Other Brahmas are preaching the gospel, and learned pandits are attacking the popular idolatry. Nearly 500 Protestant missionaries are now laboring in India (Ceylon included), with 400 principal stations and 2,000 out stations, aided by 240 native preachers, with 60,000 members of Christian churches, and 140,000 pupils in Christian schools. The whole Bible, or parts of it, and other books have been translated into 30 of the different languages of the country. And the above numbers by no means represent the entire change wrought there by missions. The increase in conversions in the last ten years is 50 per cent. greater than it was in the previous ten, and many of the churches are self-supporting, the native converts paying already $100,000 a year for the maintenance of their own Christian institutions, while other thousands have renounced idolatry and caste, who have not yet accepted Christianity. One marked indication of this is in the rise of the society called the Brahma Somaj, of which Chunder Sen, an educated Hindoo, is the acknowledged leader. Its members discard the entire Hindoo mythology, believe in one God, Creator of heaven and earth, and accept the morality of the Bible, but not the doctrines of the Trinity, atonement, &c. They are regarded as deists; and yet Chunder Sen is reported as saying: "The spirit of Christianity has pervaded the whole of Indian society, and we breathe, think, feel, and move in a Christian atmosphere. Native society is being roused, enlightened, and reformed under the influence of Christian education."—English missionaries are at work among the aborigines of Australia and in the island of Mauritius. In the latter the church missionary society has 1,118 communicants, and the society for the propagation of the gospel 594. Little or nothing has been attempted by Protestant missionaries among the people of Afghanistan, Beloochistan, or Arabia. Protestant missionaries from America entered Persia in 1854. Their work has been confined almost exclusively to the Nestorians, an ancient Christian sect, chiefly in the N. W. part of the empire; the city of Oromiah, with its 25,000 inhabitants, being the chief seat of their operations. Among the Nestorians of Persia, who number about 150,000, 7 missionaries of the American Presbyterian church are laboring, with 54 native pastors and preachers, 17 churches, 707 communicants, 70 schools, and 1,124 scholars. The cities of Tabriz and Teheran have more recently been occupied, and more direct efforts are to be made to reach the Mohammedans, some of whom have already embraced the Christian faith. The Nestorians had the Scriptures, but in an unknown tongue. The missionaries have translated the Bible into the modern Syriac, the language of the people. Constantinople has been the principal centre of operations for the 40,000,000 of the Turkish empire, especially for the work of the press. Able men have devoted much time to the translation of the Scriptures and other books into the languages of the empire. Religious papers are also published in that city and widely scattered throughout the empire. Nothing could be done at first among the Mohammedans, it being death to any Mussulman to change his religion; but that law has been abrogated, and religious liberty secured to all classes, by imperial firman, although persecution has not altogether ceased. But the labors of the missionaries have been devoted chiefly to the Armenians, Greeks, and other Christian sects, with a view to reaching the Mohammedans in the end. For this purpose 50 missionaries of the American board are now occupying most of the principal cities of the empire, not only preaching the gospel, but establishing schools, training up teachers and preachers, translating and printing books of different kinds, and giving the people opportunities for general reading, gathering converts into native churches, and ordaining native pastors over them. The Protestant churches now number over 4,000 members, and the Protestant adherents over 23,000, making one of the recognized sects or communities of the empire, with its civil head residing at the capital and guarding its interests. A great demand for education has been created by these missionary operations. Previously female education was a thing almost entirely unknown; now female seminaries and primary schools for girls are found in many parts of the empire, and thousands of women can read and are teaching others. Schools and academies for boys are multiplied, and colleges have become a necessity. One has been for years in successful operation at Constantinople, endowed chiefly by the liberality of Christopher R. Robert, a merchant of New York, whose name it bears. It has 250 students of 13 different nationalities. Another is just
starting at Aintab, a city of about 85,000 inhab-
habitants, in northern Syria. The native converts
themselves have asked for it, and have contrib-
uted liberally toward founding it. The native
Turkish schools have felt the impulse of im-
provement, and are far better than they were
before mission schools were established among
them. Training schools or theological semi-

nary are also in operation at four of the princi-
pal cities of the interior (Marsivan, Kharput,
Marash, and Mardin), to educate native minis-
ters. A similar work has been done mainly
by American missionaries in Syria, the Bible
having been translated into pure Arabic, and 60
Protestant schools established with 3,000
scholars, besides a college proper, a medical
college, and a theological seminary. In self-
defence the Greeks, Roman Catholics, and Ar-
menians of the land have started as many
more schools, to keep their children from
Protestant influences. There are about 20
missionaries in Syria, 500 church members,
and printing presses issuing 11,000,000 pages
of religious books yearly.—In 1830 the Ameri-
can board and American Episcopalians en-
tered Greece, and American Baptists followed
in 1836. The Episcopalians have done little
besides maintaining a school at Athens. Dr.
King of the American board contended ear-
nestly for liberty to preach the gospel and
make converts. Although as strongly op-
posed by the leading powers in church and
state, he finally succeeded; religious liberty
has been secured, a few churches have been
formed, and some native Greeks are preach-
ing the Protestant faith.—In Africa, with its
200,000,000 people, we find 10 missionar-
ies of the United Presbyterian church of Ameri-
can, male and female, laboring in Egypt, chiefly
among the 150,000 Copts, an ancient Christian
sect, who have been sunk for ages in a dark-
ness and superstition equal almost to any
heathenism. Their most prosperous station
is at Soot. They have 9 stations in all, 508
church members, 14 schools, 600 scholars, and
22 theological students. Miss Whately, an
English lady, has also a large school in Cairo,
and the Kaisersworth deaconesses are laboring
in Alexandria. English missionaries labored
in Abyssinia from 1829 to 1888, but were then
expelled by the king at the instance of the
Jesuits. Another mission was started in 1854,
but was soon crushed out by similar influ-
ences. The “Pilgrim Society of St. Krisna-
na” now has one missionary at Adowa, capi-
tal of Tigret, and another at Ankobah, in the
kingdom of Shoa; and eight African youths,
educated at St. Krishana, have returned un-
der the guidance of a missionary of the Lon-
don Jewish society to labor among the Jews.
Swedish missionaries are laboring at Massowah
and Allat, on the borders, where they have
met with some success in their schools. A
beginning has been made by English missionar-
ies at Zanzibar, east Africa, in two small
stations, but as yet with insignificant results.

The west coast presents a different aspect.
Between Sierra Leone and the Gaboon, a dis-
tance of nearly 2,000 miles, 12 or more Pro-
estant societies have missions, with about 20,-
000 children in Christian schools and as many
members gathered into Christian churches.
The slave trade has disappeared from this re-

region, where it formerly had 20,000 victims a
year. Mohammedanism is said to be making
some advances in the interior of Africa, while
Protestant Christianity is disputing its sway
upon the coast. About 20 societies are oper-
ating in southern Africa, among the Bushmen,
the Hottentots, the Bechuana, the Zooloo Caff-
es, and other tribes. Large colonies of Eu-

ropean settlers have occupied portions of the
country, so that the whole territory, for 1,000
miles north of the Cape of Good Hope, is pos-
sessed by these colonists, or dotted over with
mission stations among the native tribes.
Here also, as in west Africa, the people were
without written languages, or schools, or books
of any sort. The languages have been reduced
to writing, books prepared, schools established,
and churches organized, whose members are
now reckoned at 20,000, some with native
pastors over them. About 100,000 people in
southern Africa are thus recovered from he-
thenism, and have settled down to habits of
civilized life. The Lovedale educational insti-
tution of the Free church of Scotland, with a
school of 150 boys and 30 girls, is doing much
to prepare suitable teachers for the people.—
In Madagascar, inhabited by about 5,000,000
people, missionary operations were commenced
in 1818, by the London missionary society,
but soon suspended by the death of three out
of the four who composed the first missionary
party. Other missionaries landed in 1820, and
met with great success in their labors for sev-
eral years. The king favored their operations;
the language was reduced to writing; the Scrip-
tures and other books were translated into
the language; schools were established and
many converts were made. But after the
death of the king, in 1828, the queen, who
succeeded him on the throne, began to man-
ifest hostility to the new religion, soon became
a fierce and relentless persecutor, drove the
missionaries from the island, and slaughtered
thousands of her best subjects, as many as
2,000 sometimes being killed in a single year.
Yet secretly the truth was spreading all the
time, and when at length the queen died (July
16, 1861) and her own son came to the throne,
he at once proclaimed entire freedom in reli-
gious matters, and the missionaries were in-
vited to return and resume their labors. Not
long after, however, the king proved treacher-
ous and was put to death by his own nobles,
and his widow was crowned queen under a
written constitution, guaranteeing the fullest
religious liberty. Although she was herself
an idolater to the last, she was true to her
coronation oath. She died April 1, 1868, and
her sister, who succeeded to the throne, has
been friendly to the new religion from the first, and is a member of one of the native churches. Ever since the death of the first queen, the missionaries have enjoyed the largest liberty in the prosecution of their work. Nearly half a million of people have already renounced their idolatry; the state idols have been burned; large congregations are gathered every Sunday for Christian worship; thousands have learned to read, and 60,000 are numbered as communicants in the churches; a change more rapid and remarkable than in any other mission field. Turning westward again, it is something noticeable that Protestant missionaries are now laboring in Italy, Spain, and Austria; countries from which until quite recently they were excluded. The Protestant church members in Italy are now 4,000. Such are some of the changes in the old world.—In America, the labors of the missionaries among the Indians have not been altogether in vain. The Creeks, Cherokees, and Choctaws had virtually received the Christian religion 20 years ago, but the civil war deprived them for a time of their religious teachers and retarded their progress. They, however, have schools, churches, and native pastors, supported by themselves. Missionaries are also at work among the Chippewas, the Sioux, the Pawnees, the Delawares, the Oneidas, the Nez Percés, and other tribes within the territory of the United States. English missionaries are in like service in Manitoba, around Hudson’s Bay, on the Columbia, and on the Mackenzie river. Sixteen different societies have missions among the Indians of North America; and it is estimated that 10,000 of them are now members of Christian churches, and 75,000 including women and children, have settled down to habits of civilized life. The present attitude of the government is regarded as highly favorable to greater success in Christianizing the Indians. The Moravians have 24 missionary agents, 45 native assistants, and 948 communicants among the Greenlanders; and 45 missionary agents, 56 native assistants, and 434 communicants in Labrador. Through all this modern missionary era many of the blacks of the West India islands have been regarded as but little better than pagans, and English and American missionaries have labored among them with great self-denial. It is estimated that 80,000 are now members of Protestant churches. Protestant missionaries, 12 in number, are laboring in Mexico, occupying six of its principal cities, with 12 congregations in and around the capital. Great numbers of Bibles are sold; the people are asking for schools and learning to read, a new thing with them. A like work has been begun in Colombia, Chili, and Brazil, from which countries Protestant missionaries were excluded until within a few years. The Moravians have long had a prosperous mission in Surinam, and now have 18 stations, 85 missionary agents, 406 native assistants, and 6,007 communicants. In the islands of the Pacific all was pagan, and a large part cannibal, 60 years ago. The people were without written languages, without books, without schools, and sunk in the lowest degradation. English and American missionaries have vied with each other in the work of elevating them. Twenty languages have been reduced to writing. Elementary books and translations of the Scriptures have been prepared in them, schools opened, teachers trained for them, and hundreds of thousands of the people have been taught to read. Churches have been organized, and native pastors placed over them. Men are now preaching the gospel on these islands who had participated in a hundred cannibal feasts. The first missionaries to the Hawaiian islands landed there in 1820, and since that time the number of converts received into their churches is about 70,000; the present number is 12,360, gathered in 57 churches, most of them having native pastors. These churches, with some aid in men and means from the American board, themselves now sustain a foreign mission in the Micronesian islands, 3,000 miles S. W. of their own country, and another on the Marquesas islands, nearly as far S. The Hawaiian islands have been for some years regarded as Christianized, and no longer missionary ground. Like changes have occurred further south, under the labors of English missionaries, of the London, Wesleyan, and Church missionary societies. They have labored in New Zealand, and in the Society, Friendly, Feejee, and other islands, with such success that idolatry and cannibalism have disappeared from almost the whole of eastern Polynesia. More than 300 islands have almost entirely relinquished their heathenism, and more than 400,000 of these recent savages are virtually Christianized. The number of communicants gathered into their churches was long since reckoned at 50,000, and now can hardly be less than 60,000.—According to the estimates given, the number of converts now living and gathered into Christian churches by the labors of Protestant missionaries throughout the world is as follows: in China, 10,000; Burmah, 20,000; India, 60,000; Turkey, 4,000; west Africa, 20,000; south Africa, 30,000; Madagascar, 60,000; the Indians of North America, 10,000; the black of the West Indies and Guiana, 50,000; and the Pacific islanders, 60,000; making a total of 554,000 communicants, representing communities of nominal Christians to the number of nearly 2,000,000, without including the scattered few in Japan, Siam, Persia, Syria, Egypt, Greenland, Mexico, Peru, and Brazil. There are now about 2,000 Protestant missionaries engaged in the work, aided by 10,000 native pastors and preachers whom they have trained; and missionaries have translated the Bible and many other books into nearly 200 languages and dialects. Probably 100 of the missionaries are medical men, who combine the healing art with their reli-
gious instruction, and thus get access to thousands who could not otherwise be reached. From 12 to 20 medical dispensaries are in operation in India alone for the gratuitous treatment of diseases, in which generally religious services are also held. Dr. Parker treated 55,000 Chinese during his residence in Canton, relieving all sorts of maladies, exciting the liveliest gratitude in the minds of most of his patients, and preparing the way for Christian instruction. More recently female physicians have been sent to some mission fields, with special reference to reaching the women in the seclusion of their homes. In Japan Dr. Berry of the American board has induced the people to establish seven hospitals, of which he is to have the oversight. The literature of Protestant missions is very copious. Almost every missionary society publishes a periodical, which, together with the annual reports of the societies, is the most trustworthy source of information for the missionary history of a particular denomination. The number of works published by missionaries on special countries is likewise very large. Among the works extending over the whole ground are: W. Brown, "History of the Propagation of Christianity among the Heathen since the Reformation" (2 vols., London, 1814); Hune, "History of Christian Missions from the Reformation to the Present Time" (Edinburgh, 1849); Wiggers, "Geschichte der evangelischen Missionen" (2 vols., 1845–6); Handbuchlein der Missionsgeschichte und Missionsgeographie (Calv., 1844); Newcomb, " Cyclopaedia of Missions" (New York, 1860); Aikman, "Cyclopaedia of Christian Missions" (London, 1860); Anderson, "Foreign Missions, their Relations and Claims" (New York, 1860; Boston, 1870); Grundemann, "Missions-Atlas" (Gotha, 1867–71); and " Missionary World" (London, 1873).

MISSISQUOI, a S. W. county of Quebec, Canada, bordering on Vermont, and bounded S. W. by the Richelieu river; area, 358 sq. m.; pop. in 1871, 16,922, of whom 7,114 were of French, 4,513 of English, 2,138 of Irish, 1,950 of German, and 979 of Scotch origin or descent. It is indented by Missisquoi bay, an inlet of Lake Champlain, and is traversed by the N. division of the Vermont central railroad. Capital, Freihsburg.

MISSISSIPPI, one of the S. W. states of the American Union, and the seventh admitted under the federal constitution, situated between lat. 30° 13' and 35° N., and lon. 88° 7' and 91° 41' W.; extreme length N. and S., 332 m.; average breadth 142 m., varying from 78 m. below lat. 31° N. to 189 m. on that parallel, and 118 m. on the N. line; area, 47,156 sq. m. It is bounded N. by Tennessee; E. by Alabama; S. between the Alabama line and Pearl river by the gulf of Mexico, and from the Pearl to the Mississippi on the parallel of 31° by Louisiana; and W. by Louisiana and Arkansas, having below lat. 31° the Pearl river, and above that parallel the Mississippi, as the dividing lines. The state is divided into 73 counties, viz.: Adams, Alcorn, Amite, Attala, Benton, Bolivar, Calhoun, Carroll, Chickasaw, Choctaw, Claiborne, Clark, Coahoma, Colfax, Copiah, Covington, De Soto, Franklin, Greene, Grenada, Hancock, Harrison, Hinds, Holmes, Issaquena, Itawamba, Jackson, Jasper, Jefferson, Jones, Kemper, Lafayette, Lauderdale, Lawrence, Leake, Lee, Leflore, Lincoln, Lowndes, Madison, Marion, Marshall, Monroe, Montgomery, Neshoba, Newton, Noxubee, Oktibbeha, Panola, Pearl, Perry, Pike, Pontotoc, Prentiss, Rankin, Scott, Simpson, Smith, Sunner, Sunflower, Tallahatchie, Tate, Tippah, Tishomingo, Tunica, Union, Warren, Washington, Wayne, Wilkinson, Winston, Yadkin, and Yazoo. There are eight cities, viz.: Vicksburg, pop. in 1870, 12,443; Natchez, 9,057; Columbus, 4,812; Jackson, the capital, 4,384; Meridian, 3,709; Holly Springs, 2,406; Canton, 1,963; and Grenada, 1,887. The chief towns are Aberdeen, Brookhaven, Corinth, Okolona, Oxford, Pass Christian, Water Valley, and West Point, each having more than 1,000 inhabitants; and Biloxi, Brandon, Crystal Springs, Greenville, Hazlehurst, Hernando, Kosciusko, Leaf River, Lexington, Liberty, Macon, Ocean Springs, Rodney, and Tupelo, with more than 500 inhabitants each.

The population of Mississippi, according to the United States census, has been as follows:

Included in the last total are 16 Chinese and 800 Indians. Mississippi ranked 18th among the states in total population in 1870; 25th in white population, a gain since 1860 of 8,19 per
cent.; and 4th in colored population, a gain of 1.55 per cent. Of the total population at the last census, 816,731 were native and 11,191 foreign born; 413,421 males and 414,501 females. Of the colored, 398,798 were blacks and 45,403 mulattoes. Of the natives, 564,142 were born in the state, 59,520 in Alabama, 35,856 in South Carolina, 33,561 in Virginia and West Virginia, 31,804 in Tennessee, 28,960 in Georgia, 13,091 in Florida, 8,417 in Louisiana, 8,927 in Kentucky, 3,250 in Maryland, 2,410 in Missouri, 2,176 in Arkansas, 1,458 in New York, 1,171 in Ohio, and 1,145 in Texas. Of the foreigners, 3,859 were natives of Ireland, 2,960 of Germany, 1,088 of England, 970 of Sweden, and 630 of France. There were 138,542 persons born in the state living in other states and territories. The number of male citizens of the United States 21 years old and upward in the state was 103,727. There were 166,828 families, with an average of 4.96 persons to each, and 164,150 dwellings, with an average of 5.04 persons to each. There were 291,718 persons 10 years old and over who could not read, and 313,310 who could not write, of whom 151,255 were males and 162,045 females, 48,028 whites, 264,902 colored, and 380 Indians and Chinese; 61,470 were between 10 and 15 years of age, 60,365 between 15 and 21, and 191,451 21 years old and upward (9,837 white males and 80,810 colored males). The number of blind persons in the state was 474; deaf and dumb, 245; insane, 245; idiotic, 485. The number of paupers supported during the year ending June 1, 1870, was 921, at a cost of $96,707; receiving support at that date, 809; number of persons convicted of crimes during the year, 471; in prison at the close, 449. Of the whole number of persons 10 years old and over returned as engaged in occupations (618,850), 259,199 were employed in agriculture, 40,503 in professional and personal services, 9,148 in trade and transportation, and 9,981 in manufactures and mining. Among special occupations represented there were 181,523 agricultural laborers, 77,102 farmers and planters, 749 clergymen, 15,836 domestic servants, 15,969 laborers, 1,869 laundresses and laundresses, 682 lawyers, 743 government officials and employees, 1,511 physicians and surgeons, 1,524 teachers, 3,834 traders and dealers, 2,429 clerks, salesmen, and accountants, 1,415 officials and employees of railroad companies, 500 draymen, teamsters, &c., 1,238 blacksmiths, 2,072 carpenters and joiners, 501 cotton and woolen mill operatives, and 573 milliners and dressmakers.—Except in the Mississippi bottom, the surface of the state is generally hilly or undulating, with a slope S. W. and S. Few of the ridges rise as high as 400 ft. above the drainage of the surrounding country, the usual elevation being from 30 to 120 ft. above the minor watercourses, and probably none is 800 ft. above the sea. The Mississippi bottom comprises an elliptical area, extending from Vicksburg N. to the Tennessee line, and em-
its mouth. The Tombigbee river rises in the N. E. part of Mississippi, and flows into Alabama; it is navigable to Cottonginport, 10 m. above Aberdeen.—Four geological periods, the carboniferous, cretaceous, tertiary, and post-tertiary, are represented. The first occurs only in the N. E. corner, and consists chiefly of limestone, chert or hornstone, and siliceous sandstone. W. and S. of this is the cretaceous, occupying a triangular area, extending W. along the Tennessee line beyond the Hatchie river (about 35 m.) and S. along the Alabama border beyond Macon (about 125 m.). This formation, which contains many fossils, consists of four groups, the Eutaw, the Tombigbee sand group, the rotten limestone, and the Ripley group. The tertiary occupies the rest of the state, except the W. portion along the Mississippi river, and consists of seven groups, viz.: the northern lignitic, the silicious Claiborne, the calcareous Claiborne, the Jackson, the Vicksburg, the Grand Gulf, and the coast plicocene. The post-tertiary has four principal divisions: the orange sand, the bluff, the yellow loam, and the alluvial formations. The first consists of siliceous sands, usually colored with hydrated peroxide of iron or orange-yellow ochre, and overlies the carboniferous, cretaceous, and tertiary formations, though wanting in portions of the Jackson and rotten limestone groups and in the flatwoods. It also occurs to some extent in the bluff formation, which coincides with the district already described as the cane hills, and likewise stretches in a narrow belt along the E. margin of the Mississippi bottom. Deposits of yellow, brown, or reddish loam form the actual surface of the greater portion of the state. The alluvium occupies the Mississippi bottom and is separated from the northern lignitic by the narrow belt of the bluff formation.—Except in the Mississippi bottom, where malarial fevers frequently occur in summer, the state is generally healthy. The summers are long and hot, the winters somewhat colder than in the same latitude on the Atlantic coast. The mean temperature of the year ending Sept. 30, 1872, at Vicksburg (lat. 32° 28'), was 66°4; of the warmest month (August), 84°6; of the coldest month (January), 42°7; total annual rainfall, 57.77 inches. The mean temperature of the succeeding year at the same place was 64°7; warmest months (July and August), 82°; coldest month (January), 43°; total rainfall, 48.04 inches. The number of deaths in 1870 was 9,172, of which 2,883 were from general diseases, 1,043 from diseases of the nervous, 224 of the circulatory, 1,707 of the respiratory, and 1,274 of the digestive system. Among special diseases, measles proved fatal in 272 cases, enteric fever in 383, intermittent fever in 377, remittent fever in 256, whooping cough in 158, consumption in 895, dropsy in 193, encephalitis in 288, meningitis in 125, apoplexy in 66, convulsions in 180, croup in 281, pneumonia in 1,177, enteritis in 287, dysentery in 108, diarrhoea in 325, and cholera infantum in 143.—The soil of the Mississippi bottom is very fertile. The region E. of this, characterized by the deposits of yellow loam, is generally fertile, though in places easily exhausted. The N. E. portion, except the prairies, is less productive. The cane hills and the central belt of the state possess a generally productive soil. The S. region has a generally poor and sandy soil, particularly along the coast. The principal forest trees in the uplands of the N. portion of the state and in the bluff region are the short-leaved pine, various species of oak, the chestnut, hickory, poplar, black walnut, locust, beech, gum, holly, basswood, sassafras, elm, and magnolia. The prevalent growth of the sandy region in the south is the long-leaved pine. The islands are partially covered with sparse forests of pitch pine; this species also occurs on the mainland near the coast. In the swamps and bottoms are dense thickets of cane and cypress. The prairies where uncultivated are covered with grass during the greater part of the year, and the forests of long-leaved pine have commonly an undergrowth of long grass, which affords good pasturage. Cotton (the production of which Mississippi surpassed all other states in 1870) and Indian corn are the staple crops. Wheat and other grains are grown in the north, and rice and the sugar cane in the south. All the fruits of temperate climates grow here in perfection; plums, peaches, and figs are abundant, and in the south the orange. The deer, cougar (commonly called panther), wolf, bear, and wild cat are still common. Alligators occur in the Mississippi as far N. as the mouth of the Arkansas, and in some of the smaller rivers; and most of the streams abound in fish. Porpoises are seen as far N. as Natchez, and wild turkeys and pigeons abound. Oysters and fish are abundant in Mississippi sound.—According to the census of 1870, the number of farms was 68,023, of which 11,003 contained less than 10 acres each, 8,981 from 10 to 20, 26,048 from 20 to 50, 11,967 from 50 to 100, 8,938 from 100 to 500, 853 from 500 to 1,000, and 283 more than 1,000 acres. There were 4,209,140 acres of improved land in farms; cash value of farms, $81,716,576; of farming implements and machinery, $4,458,653; wages paid during the year, including the value of board, $10,326,794; estimated value of all farm productions, including betterments and additions to stock, $73,187,055; value of orchard products, $71,018; of produce of market gardens, $61,735; of forest products, $93,975; of home manufactures, $505,298; of animals slaughtered or sold for slaughter, $4,090,818; of live stock, $29,940,283. The productions were 66,638 bales of spring wheat, 207,841 of winter wheat, 14,852 of rye, 15,637,316 of Indian corn, 414,586 of oats, 5,793 of barley, 1,618 of buckwheat, 176,417 of peas and beans, 214,189 of Irish potatoes, 1,713,432 of sweet potatoes, 6 of
The foreign trade of Mississippi is indirect, and almost entirely through New Orleans and Mobile. Cotton and lumber are the chief exports. The coasting and river trade is large. The coasting trade is chiefly directed to Mobile and New Orleans, while the Mississippi river trade centres in the latter, and that of the Tombigbee in Mobile. The railroads terminating at these two ports and at Memphis are also large carriers of merchandise. There are three customs districts: Natchez, Pearl River (port of entry, Shilohsborough), and Vicksburg. The direct foreign and the coasting trade are centred entirely in the district of the Pearl River. The principal industries are as follows:

The following lines are projected or in progress: the Natchez, Jackson, and Columbus railroad, from Natchez to Columbus (180 m.); Vicksburg and Nashville, from Vicksburg to Nashville, Tenn. (380 m.), with a branch from Grenada to the Mississippi river, opposite Eunice, Ark. (90 m.); Selma, Marion, and Memphis, from Selma, Ala., to Memphis, Tenn. (280 m.); Mississippi Valley and Ship Island, from Vicksburg to Mississippi City (210 m.); and Vicksburg
and Brunswick, from Eufaula, Ala., to Meridian (225 m.).—There are no national banks in Mississippi. In 1874 there were six savings banks, with an aggregate capital of about $300,000, and five banks of deposit, incorporated under state law, with an aggregate capital of about $560,000. One of each class also does an insurance business. At the close of 1873, 21 insurance companies of other states and countries were doing business in the state.

The government is administered under the constitution of 1869, which declares that all citizens of the United States resident in the state are citizens thereof; that no property or religious qualification for office, nor any property or educational qualification for voting, shall ever be required; that neither slavery nor involuntary servitude, except in punishment of crime, shall exist; that no law in derogation of the paramount allegiance of citizens to the United States shall be passed, and that the right of secession shall never be assumed; that no public money shall be appropriated for any charitable or other public institution making any distinction among citizens of the state; and that any person engaging in or abetting a duel shall be disfrocked and disqualified from holding office. The executive power is vested in a governor, lieutenant governor, secretary of state, treasurer, auditor, attorney general, and superintendent of public education, elected by the people for a term of four years, and a commissioner of immigration and agriculture, chosen by joint ballot of the two houses of the legislature for the same term. The governor's veto may be overcome by a two-thirds vote of both houses of the legislature. Senators are elected by senatorial districts for four years, one half retiring biennially; their number (at present 37) cannot be less than one fourth nor more than one third of that of the representatives. The representatives are elected for two years; their number cannot be less than 100 nor greater than 120 (at present 115). The judicial power is vested in a supreme court, circuit courts, chancery courts, and justices of the peace. The supreme court has appellate jurisdiction only, and consists of three judges (one from each of the three districts into which the state is divided), appointed by the governor with the consent of the senate for nine years, one retiring every three years. A session is held twice a year at the capital. There is a circuit court for each of the 15 judicial districts, presided over by a single judge appointed by the governor with the consent of the senate for six years. These courts have original jurisdiction in criminal matters and in civil cases at law when the amount in dispute exceeds $150, and are held at least twice a year in each county. The chancery courts have jurisdiction of equity and probate matters, and are held at least four times a year in each county. A chancellor is appointed by the governor with the consent of the senate for four years for each of the 20 chancery districts. Justices of the peace are elected for two years, and have jurisdiction of civil cases at law when the amount in dispute does not exceed $150. The right of suffrage is conferred upon all male citizens of the United States (except convicts and persons of unsound mind) 21 years old and upward, who have resided in the state six months and in the county one month, and have been registered. Elections are by ballot, and occur biennially (odd years) on the Tuesday next after the first Monday in November. The political year commences on the first Monday of January, and the legislature meets annually on the following Tuesday. No one who denies the existence of a Supreme Being, or who is not a qualified elector, can hold office. The militia consists of all able-bodied male citizens between the ages of 18 and 45. It is provided that the state shall not become a stockholder in any corporation or association, nor pledge or lend its credit in aid of any person, corporation, or association; that no bank of issue shall be created or renewed, and that the legislature shall by law prohibit individuals or corporations from issuing bills as money. Amendments to the constitution must be proposed by a two-thirds vote of each house of the legislature, published for at least three months preceding the next general election, and ratified by the people. Treason, murder, and arson committed in the night upon a dwelling are punished with death. Other punishments are fines and imprisonment. The chief grounds of divorce are adultery, sentence to the penitentiary, impotence, desertion for two years, habitual drunkenness, cruel treatment, and pregnancy at the time of marriage by another unknown to the husband. A married woman may convey and devise property belonging to her at the time of marriage or afterward acquired if single, and the same is not liable for the debts of her husband, and she may do business as a feme sole. The rate of interest is 6 per cent., but 10 per cent. may be stipulated for by special contract. Mississippi is entitled to two senators and six representatives in congress, and has therefore eight votes in the electoral college. The valuation of property according to the United States censuses has been as follows:

<table>

The diminution in the value of personal property is chiefly due to the emancipation of the slaves. The total taxation not national in 1870 was $3,736,432, of which $1,309,655 was state, $2,399,699 county, and $127,078 town, city, &c.; total debt, $2,594,415, of which $1,796,230, including $1,138,494 due to the educa-
tional funds, was state, $656,585 county, and $141,600 town, city, &c. The state held bonds and stocks to the amount of $966,674 as security for loans to railroads, &c. According to the treasurer's report, the receipts into the treasury during the year ending Dec. 31, 1873, including $174,670 70 on hand Jan. 1, but excluding uncurrent and worthless funds in the treasury to the amount of $756,650 48, were $1,392,829, of which $366,129 71 from state taxes, $34,883 8 from the tax on privileges, $116,345 86 from the penitentiary, $240, 191 05 from the school funds, and $381,650 from the bonds (loans). The disbursements amounted to $1,244,475 89, of which $98,- 113 62 were for legislative expenses, $247,- 803 70 judiciary, $81,951 57 executive, $137,- 546 71 on account of the penitentiary, $606,- 561 93 public printing, $32,350 university of Mississippi, $88,145 lunatic asylum, $10,916 15 executive contingent fund, $72,849 46 interest on Chickasaw school fund, $3,153 76 geological survey, $6,887 50 institution for the blind, $17,100 deaf and dumb asylum, $88,500 Alcorn university, $83,450 state normal schools, $2,730 90 capital repairs, $19,237 97 repairs on lunatic asylum, $89,504 79 on account of common school fund, $100,000 in payment of state bonds, $10,204 40 for interest on state bonds, and $17,409 77 for interest on deposits of insurance companies; balance on hand Jan. 1, 1874, in current funds, $88,831 11. The state debt on that date amounted to $5,558,629 24, viz.: due school funds, $1,157,415 69; certificates of debt, $294,150; auditor's warrants, $1,083,082 57; bonds, $634,650; interest on bonds, $73,456; interest on insurance deposits, $15,294 98. Of the bonds $100,000 were payable on Jan. 1, 1874, 1875, and 1876; $150,- 000 on Jan. 1, 1875 and 1876; and $34,650 on Jan. 1, 1877. This statement of the debt does not include bonds to the amount of $7,600,000, of which the principal and interest were re- mained unpaid since 1842. The state insti- tutions are the penitentiary, blind institute, institute for the deaf and dumb, and lunatic asylum, situated at Jackson. The penitentiary contains 200 cells, and is inadequate for the accommodation of the prisoners. The convicts are partly employed within the walls in manu- factures, and partly leased to persons who employ them on public works in different parts of the state. The number on Nov. 30, 1872, was 218; received during the year, 227; remaining Nov. 30, 1873, 258, of whom 35 were whites and 253 colored, 280 males and 8 fe- males; 121 were confined within the walls, 125 employed on railroads, and 42 on leevess. The number of officers on July 23, 1874, was 21; of convicts, 280. In the blind institute, besides a literary training, the male pupils receive instruction in broom making, mattress making, and chair seating, and the females in domestic work. The number under instruc- tion in 1873 was 25; remaining at the close of the year, 21; number of officers and teachers, 5. The number under instruction during the year in the institute for the deaf and dumb was 50, of whom 40 were males and 10 semi- nutes, 26 males and 24 females; average at- tendance, 39; remaining at its close, 36; number of officers and instructors, 5. Pupils unable to pay for tuition are educated free. The building requires enlargement. The lunatic asylum on Dec. 1, 1872, had 231 inmates; re- ceived during the ensuing 13 months, 197; re- maining Dec. 1, 1873, 304, of whom 150 were males and 154 females; number of officers, 4. The number received since the opening of the asylum was 1,008 (550 males and 449 females); discharged recovered, 258; discharged improved, 66; discharged stationary, 129; eloped, 53; died, 204. The building was enlarged in 1872, but is still overcrowded.—The constitu- tion requires the establishment of a system of free public schools for all youth between the ages of 5 and 21 years, and an act was passed in 1871 to carry this provision into effect. The schools are under the general charge of the state superintendent of public education; that officer, the secretary of state, and the at- torney general form the state board of education. There is a superintendent for each county, appointed by the board of education with the consent of the senate for two years. Each county and each incorporated city of more than 3,000 inhabitants forms a school district, and has a board of six school directors, 137; those for the cities being elected by the qualified voters, and those for the school districts out- side of cities by the patrons of the schools. One or more free public schools, open to all of school age, are to be kept in each county for at least four months in each year. Teacher- ers' institutes are to be held annually, under the general supervision of the state superin- tendent, for at least two weeks in each con- gressional district. According to the report of the state superintendent for the period from Jan. 1 to Aug. 31, 1873, returns had been received from 54 counties, reporting 252,962 youth of school age, 1,940 public schools, and 465 private schools; number of pupils enrolled in public schools, 78,066; teachers in same, 2,180; pupils enrolled in private schools (56 counties), 9,718. In 5 of the counties reporting there were private but no public schools, and in 10 public schools were in operation, but no private ones. In 35 counties, having 133, 468 pupils enrolled in public schools, the aver- age attendance was 46,240. The superinten- dent estimates the number of public schools in operation in the entire state during the period at 2,000, of which 300 were of the first, 700 of the second, and 1,000 of the third grade; number of private schools, 500; pupils enrolled in public schools, 60,000; in private schools, 12,000; average attendance in public schools, 50,500; number of teachers in pub- lic schools, 1,800; length of school term, 4 months; number of school houses, including buildings rented, 4,700; built during the year,
200; value of public school property, $1,000,000; probable number of public schools to be in operation during the year 1873-'4, 3,000. The common school fund amounted to $1,950,000; amount of revenue accruing to the fund from various sources provided by the constitution and laws, $615,968 49; amount reported as arising from capitation and special county taxes, $602,481 36; total, $2,565,963 49. The reported expenditures were as follows: teachers' wages, $336,345 37; salaries of school officers, $79,381 11; school houses and contingencies, $65,935 32; total estimated cost of conducting the schools, including normal schools, $492,500. The average monthly wages of teachers was $50; number of teachers' institutes held, 6; number of lectures delivered by school officers on educational topics, 127; number of school districts, 79. There are two state normal schools, devoted to the training of teachers for the colored schools. One of these is connected with Tougaloo university; the other was organized in 1870 at Holly Springs, and in 1873 had 3 instructors and 129 pupils. Each member of the legislature is entitled to nominate one pupil for this school, who is instructed gratuitously. In the Tougaloo school, which was established by the act of Jan. 2, 1872, each county is entitled to the free tuition of two students, to be appointed by the county superintendent of education. The beneficiaries in the normal schools are required to sign a declaration of intention to make teaching a profession and to teach in the public schools of the state for at least three years. In 1870, according to the United States census, the number of schools of all classes was 1,564, with 1,054 male and 674 female teachers, 22,793 male and 20,658 female pupils, and an annual income of $789,399 ($11,600 from endowment, $167,414 from public funds, and $601,425 from other sources, including tuition). The schools were classified as follows: classical, 19 (18 colleges and 1 academy); professional, 1 (law); technical, 1 (for the blind); day and boarding, 1,542; parochial and charity, 1. There were at that time no public schools in the state.—The statistics of the principal collegiate institutions of Mississippi for 1873-'4 are as follows:

The University of Mississippi, chartered in 1814, embraces three departments: preparatory education; science, literature, and the arts; and professional education. The department of science, literature, and the arts includes six courses: four undergraduate (for bachelor of arts, four years; for bachelor of science, four years; for bachelor of philosophy, three years; and for civil engineer, four years), and two post-graduate (for master of arts and for doctor of philosophy). Students in this department may also pursue selected studies. Candidates for the post-graduate degrees must have previously obtained the degree of bachelor of arts, or are required to sustain an examination in the studies requisite for that degree. The department of professional education embraces the school of law, the school of medicine and surgery (not yet organized), and the college of agriculture and the mechanic arts. The diploma of the law school, which may be obtained upon passing a satisfactory examination at the expiration of a year's attendance, entitles the recipient to practise law in any court of the state. The college of agriculture and the mechanic arts was established by a legislative act of 1871, which bestowed upon it two fifths of the proceeds of the 210,000 acres of land granted by congress to the state for the endowment of such an institution. The fund amounted to $75,500. The college has a farm connected with it, and confers the degree of bachelor of scientific agriculture upon graduates of the four years' course. In the department of science, literature, and the arts, and in the college of agriculture and the mechanic arts, tuition is free to students residing in Mississippi. Students preparing for the ministry and those pecuniarily unable to pay also have their tuition fees remitted. A state scholarship of $100 a year for four years was provided by an act of 1871 for one student from each representative district or county, to be selected by a board of examiners from pupils of the free schools. Alcorn university was incorporated by the act of May 13, 1871, which appropriated $50,000 a year for 10 years for its support, and also bestowed upon it three fifths of the proceeds of the congressional land grant,
amounting to $113,400, the income to be devoted to the maintenance of an agricultural and mechanical department. It occupies the site of the institution formerly known as Oak-

land college. The farm consists of 295 acres. There are an academic department (English), a collegiate preparatory department of two years, a collegiate department of four years (with a classical and a scientific course), and special courses in agriculture and mechanical engineering of four years. Students are admitted without distinction of color. Tuition is free to students residing in Mississippi, and there are the same state scholarships as in the university of Mississippi. In Tougaloo university primary, intermediate, and normal departments, and a theological class, have been organized. The classical department is not yet fully organized. Workshops and a farm of 500 acres are connected with the institution, which enable students to support themselves by labor wholly or in part. The number of students in the normal department in 1872-3 was 55. Shaw university has preparatory, normal, collegiate, theological, and law departments. Tuition is free, except in the law department, the instructors being paid by the freedmen's aid society. The other institutions mentioned in the table, besides a collegiate course, have preparatory and in some cases primary departments.—The census of 1870 returns 2,788 libraries, containing 488,482 volumes, of which 2,251, with 400, 106 volumes, were private. The others were classified as follows: state, 1, with 7,000 volumes; town, city, &c., 2, with 1,000; court and law, 3, with 121; college, 1, with 5,000; Sabbath school, 508, with 69,825; church, 15, with 3,000. The number of newspapers and periodicals was 111, issuing 4,705,336 copies annually, and having a circulation of 71,868, viz.: 3 daily, circulation 2,300; 6 tri-weekly, 3,650; 3 semi-weekly, 2,400; 92 weekly, 60,018; 2 semi-monthly, 700; 5 monthly, 2,800. They were classified as follows: agricultural and horticultural, 2; benevolent and secret societies, 1; commercial and financial, 4; illustrated, literary, and miscellaneous, 2; political, 97; religious, 3; technical and professional, 1.

—De Soto and his companions were the first Europeans who traversed this region. They made no settlements, and the death of the leader in 1542 put an end to the expedition. In 1682 La Salle descended the Mississippi, took formal possession of the adjacent country for the king of France, and called it Louisiana. In 1689 Iberville was authorized by the French king to colonize the regions of the lower Mississippi. He landed on Ship island, and in 1699 erected a fort at the bay of Biloxi, about 80 m. E. of the site of New Orleans. In 1716 Fort Rosalie was established on 78 to Natchez. The colonies grew slowly, and New Orleans, being founded soon after, attracted many of the settlers. In 1728, 1738, and 1759 the settlements suffered much from Indian hostilities. After the cession of the E. part of Louisiana (including what is now Mississippi) to Great Britain in 1763, and until the revolutionary war, immigration into the territory proceeded slowly. The territory of Mississippi was formed by the act of congress of April 7, 1798, being bounded N. by a line drawn due E. from the mouth of the Yazoo river to the Chattahoochee, E. by the Chattahoochee, S. by the 31st parallel, and W. by the Mississippi river. By the act of March 27, 1804, the region N. of these limits and S. of Tennessee, which had been ceded to the United States by Georgia in 1802, was added, and Mississippi territory thus comprised the whole of the present states of Alabama and Mississippi N. of the 31st parallel. The region S. of that parallel, between the Pearl and Perdido rivers, was added by the act of May 14, 1812, having been taken possession of by the United States in 1811 as a part of the Louisiana purchase of 1803, though claimed by Spain. Alabama territory was formed from the E. portion by the act of March 3, 1817, and by a joint resolution of Dec. 10 of the same year Mississippi was admitted into the Union as a state. In 1832 a new constitution was adopted. At the presidential election in November, 1860, 2,983 votes were cast for Douglas, 40,797 for Breckenridge; and 25,049 for Bell. Immediately after the election of Lincoln became known, the governor called an extra session of the legislature, which met on Nov. 26, and provided for an election on Dec. 10 of delegates to a convention to assemble on Jan. 7, 1861. On Jan. 9 this convention passed an ordinance of secession by a vote of 84 to 13, and on March 30 ratified the constitution of the Confederate States by a vote of 78 to 7, a resolution to submit it to a vote of the people having been rejected. The first movement of the federal troops in the state was the capture of Biloxi and the removal of a battery of two guns by a force from Ship island, on Dec. 31, 1861. During 1862 the N. portion of the state was the theatre of operations. After the battle of Shiloh the confederates retired to Corinth. The federal troops subsequently advanced in force under Gen. Halleck, the town was evacuated, and the fed-
eralists took possession on May 30. On Sept. 19 a sharp engagement took place near Juka between the confederates under Gen. Price and the federals under Gen. Rosecrans, which resulted in the evacuation of that place by the confederates during the following night. Price, joined by other forces, made an attack on Corinth July 30, Aug. 3 and 4, but was repulsed with heavy loss. (See CORINTH.) The most important operations in 1863 were those resulting in the surrender of Vicksburg on July 4. (See VICKSBURG.) Subsequent military movements were of minor importance. On May 18, 1865, the legislature assembled under a call of the governor, and ordered an election on June 19 of delegates to a convention to meet on July 3. But on June 13 President Johnson appointed William L. Sharkey provisional governor, who immediately entered upon the duties of his office, and on July 1 ordered an election, to be held on Aug. 7, of delegates to a convention, those being entitled to vote who were qualified electors under the laws in force prior to secession, and who had taken the amnesty oath prescribed by the proclamation of the president of May 29. The convention met Aug. 14. On the 21st the convention was amended by abolishing slavery, and on the following day the ordinance of secession was repealed. On Oct. 2 an election of state officers and congressmen was held, which resulted in the choice of Benjamin G. Humphreys as governor. The legislature elected at this time assembled on the 16th, and subsequently chose United States senators. But the congressmen and senators were not admitted to their seats. By the congressional reconstruction acts of 1867, Mississippi with Arkansas was constituted the fourth military district, under command of Maj. Gen. E. O. C. Ord. A registration was ordered, and on Nov. 5 an election was held to determine the question of calling a convention and for the choice of delegates to the same, which resulted in 99,790 votes for and 6,977 against a convention. On Dec. 28 Gen. Ord was directed to turn over his command to Gen. A. C. Gillem. The convention assembled on Jan. 7, 1868, and remained in session till May 18, when it adjourned after adopting a constitution. On June 4 Gen. Irwin McDowell assumed command of the fourth district, and on the 16th appointed Maj. Gen. Adelbert Ames provisional governor of Mississippi, in place of Gov. Humphreys. At an election held on June 22 the constitution was rejected by a vote of 36,231 to 63,860. In July Gen. Gillem relieved Gen. McDowell. Soon after the inauguration of President Grant (March 4, 1869) Gen. Ames was appointed to the command of the district. On April 10 an act of congress was passed authorizing the president to submit the constitution again to a vote of the people, with such clauses separate as he might deem proper. A proclamation of July 13 appointed Nov. 30 as the day of election, and designated certain clauses for a separate vote, the most important of which were those disfranchising and disqualifying from holding office persons who had taken part against the Union in the civil war. The constitution was ratified almost unanimously, and the objectionable clauses were rejected. At the same time James L. Alcorn, republican, was elected governor over Louis Dent, conservative, by a vote of 76,186 against 38,097. The legislature met on Jan. 11, 1870, and shortly after ratified the 14th and 15th amendments to the constitution of the United States. On Feb. 23 an act was passed by congress for the readmission of the state into the Union, and on March 10 Gov. Alcorn was inaugurated and the civil authorities assumed control.—See "Report on the Geology and Agriculture of the State of Mississippi," by Eugene W. Hillard (Jackson, 1869).

MISSISSIPPI. I. A N.E. county of Arkansas, bordering on Missouri, separated on the E. from Tennessee by the Mississippi river, bounded W. by the St. Francis river and Lake St. Francis, and intersected by Little river; area, 1,080 sq. m.; pop. in 1870, 3,633, of whom 971 were colored. The surface is low and level, and in the drier portions very fertile, and there are several lakes, the largest of which is Big lake. The chief productions in 1870 were 120,700 bushels of Indian corn, 11,192 of potatoes, and 3,857 bales of cotton. There were 695 horses, 465 mules and asses, 1,847 milk cows, 2,541 other cattle, 583 sheep, and 6,263 swine. Capital, Osceola. II. A S.E. county of Missouri, bounded N. E. and S. by the Mississippi river, which separates it from Illinois and Kentucky, and drained by James and Cypress bayous; area, 380 sq. m.; pop. in 1870, 4,982, of whom 919 were colored. The surface is level and the soil very fertile. The St. Louis and Iron Mountain railroad passes through it. The chief productions in 1870 were 5,225 bushels of wheat, 491,590 of Indian corn, 4,583 of oats, and 57 bales of cotton. There were 382 horses, 258 mules and asses, 1,172 milk cows, 2,814 other cattle, 659 sheep, and 14,588 swine. Capital, Charleston.

MISSISSIPPI RIVER (Indian, M"iche Sepe, as spelled by some old writers, and translated the "Great River" and "the Great Father of Waters"), the principal river of North America, and, in connection with its largest tributary the Missouri, the longest river in the world, except perhaps the Nile. It drains the greater part of the territory of the United States lying between the Alleghany and Rocky mountains, a region nearly half as large as Europe. The true Mississippi river begins at the confluence of the Missouri and the Upper Mississippi. It has eight principal tributaries, which, in the order of the extent of the regions drained by them, are the Missouri, Ohio, Upper Mississippi, Arkansas, Red, White, Yazoo, and St. Francis. The source of the Mississippi, according to Schoolcraft, who visited it in 1832, is a lake called by him Itacea, by the Chippewa
Indians Omoahkos Sagaion, and by the French traders Lac la Biche. It is a beautiful sheet of water, clear and deep, about 7 m. long and 1 m. to 3 m. wide, in lat. 47° 14' N., lon. 95° 2' W., about 1,575 ft. above the sea. Five creeks fall into Lake Itasca, the principal one of which has its origin about 6 m. distant, in a pond formed by water oozing from the bases of the hills known as Hauteurs de Terre, which are about 100 ft. high. The Mississipi at the outlet of this lake is 10 or 12 ft. wide and 18 in. deep, and flows N. E. over petty falls and rapids through a series of small lakes and marshes till it reaches Lac Travers, its most norther point. This is a beautiful sheet of water from 10 to 12 m. long and from 4 to 5 m. wide, surrounded by wooded hills sloping to a beach of pure white sand. From Lac Travers the river flows S. E. and S., and in the first 25 m. is broken into a series of small rapids, from the foot of which it flows with an even current 40 or 50 yards wide and from 2 to 6 ft. deep to Cass lake, which has an area of about 120 sq. m.; thence S. through a series of savannas, separated by several lakes, to the falls of Peckagama, where it is compressed into a channel 80 ft. wide. Here the river rushes down a rugged bed of sandstone 20 ft. in 300 yards. Below these falls the river is very crooked, and averages about 40 yards in width. It is broken by six rapids between Swan and Sandy Lake rivers. Savanna river, lying between the Sandy lake, and is the main canoe route between the Mississipi and Lake Superior. From the outlet of Sandy lake to Pine river, 100 m., the river presents several rapids and islands, and receives a number of small tributaries. Crow Wing river, the largest tributary above the falls of St. Anthony, is nearly equal to the Mississipi itself. The Elk river, the Little falls, Big falls, Prairie rapids, and St. Francis river follow in the order named; and finally the falls of St. Anthony are reached, where the river pitches over an oblong nearly parallel face of sandstone 18 ft. high. An island at the brink of the falls divides the current into two channels, the largest of which flows by the west side, and affords a great water power. Including the rapids above and below the falls, the entire descent of the river is about 65 ft. within three quarters of a mile. These rapids are about 2,200 m. from the gulf of Mexico, and constitute the natural head of steamboat navigation; but small vessels ply regularly above the falls for several hundred miles, according to the stage of water. The next natural obstruction to navigation below the falls of St. Anthony are the Rock Island rapids, extending from Leclaire to the cities of Rock Island and Davenport, a distance of 14 m. The descent is 24 ft. at extreme low water. The bed of the river throughout the rapids is stratified limestone, more or less folded, and forming chains or barriers which extend entirely across the channel at six or seven points. In 1866 congress directed the removal of these chains, and also the improvement of the lower or Des Moines rapid, 130 m. below the upper rapid, and between Montrose and Keokuk. The length of the latter is 12 m., and the descent 23 ft. at low water. Before the improvements were undertaken, there was about 11 m. of deep water and good navigation on the upper rapids, and only 53 m. on the lower rapids. The duty of devising plans for the improvement of the rapids was assigned to Gen. J. H. Wilson, U. S. A., who recommended that the obstruction at the upper rapids should be removed mainly by the use of coffer dams (see DAM, vol. v., p. 650), and that the lower rapids should be improved by similar means, supplemented by a lateral canal 7 m. long, 300 ft. wide, and having three locks each 80 ft. wide and 350 ft. long. A board of engineers approved these plans, and congress ordered them to be carried into effect. The improvements, under the supervision of Gen. Wilson and his successor Col. Macomb, have been pushed forward as fast as the appropriations would permit, and are now (November, 1874) almost completed at the upper rapids, while four fifths of the work has been done at the lower rapids. The improvements will cost about $5,000,000, and when completed will enable the largest boats to pass the rapids, whenever they can reach them either from above or below. But the navigation of the entire Upper Mississipi is rendered very difficult during the dry season by the frequent recurrence of sand bars; and although the government has done something by the use of dredge boats and wing dams to deepen the water on the worst of these, no systematic plan of improvement has yet been devised or can be carried out till a much denser and richer population shall inhabit the regions to be benefited. But it is safe to say that between the falls of St. Anthony and the mouth of the Ohio there is water enough and it is now, if properly regulated and controlled, to give a navigable depth of 6 ft. and ample width for all uses to which it can be put.—The Mississipi river, from the mouth of the Missouri to the gulf, is 1,286 m. long; from the source of the Upper Mississipi, 2,616 m. The distance from the Madison fork source of the Missouri to the gulf is 4,114 m., and from the head of the Ohio river at Cloudersport, Pa., to the gulf, 2,561 m. The numerous branches of the navigable waters connected with the Mississipi penetrate all the states and territories between the Rocky and Alleghany mountains. The capacity of these branches for navigation has been as yet only partially developed, but a careful compilation shows that they constitute a natural system of water communication having an aggregate extent of about 15,000 m.—The following table, taken from Humphreys and Abbot's "Report upon the Hydraulics of the Mississipi River" (4to, Philadelphia, 1801), shows the area of the basins, downfall of rain, and annual drainage of the Mississipi and its principal tributaries:
Below the mouth of Red river, the Mississippi is divided into numerous arms or passes, each of which pursues an independent course to the gulf. The highest of these is the Atchafalaya on the W. side of the river. Below its point of separation from the Mississippi the region of swampy lands, of bayous and creeks, is known as the delta. Above this the alluvial plain of the river extends to the Chandl, 30 m. above the mouth of the Ohio, and to Cape Girardeau in Missouri, where precipitous rocky banks are first met with. These are the lower secondary limestone strata lying in nearly horizontal beds. The total length of the plain from the mouth of the Ohio to the gulf is estimated at 500 m. Its breadth at the upper extremity varies from 30 to 50 m.; at Memphis it is about 30 m., and at the mouth of White river 80 m. The extreme width of the delta is rated at 150 m., its average width is probably 90 m., and its area 13,300 sq. m. The elevation of the bottom lands at Cairo above the sea level is about 310 ft., while the slope of the high-water surface from that place to the gulf is from 322 to 0. These bottom lands are subject to inundation, and consequent annual enrichment. Under the system of slave labor large plantations were opened in the dense forests which cover them, but vast tracts of unsurpassed fertility are yet covered with canebrakes and cypress. The alluvial plain, extending from above Cairo to the gulf, is terminated on the east and west by a line of bluffs of irregular height and direction, composed of strata of the eocene and later tertiary formations. Down this plain the river flows in a serpentine course, frequently washing the base of the hills on the E. side, as at Columbus, Randolph, Memphis, Vicksburg, Grand Gulf, Natchez, and Baton Rouge, and once passing to the opposite side at Helena. The actual length of the river from the mouth of the Ohio to the gulf is 1,907 m., increasing the distance in a straight line by about 600 m., and by its flexures also reducing the rate of its descent to less than half the inclination of the plain down which it flows. The range between high and low water at Cairo, near the head of the plain, is 51 ft., and at New Orleans it is 144 ft. The river flows in a trough about 4,470 ft. wide at the head, and 3,000 ft. at the foot. The immense curves of the stream in its course through the alluvial plain sweep around in half circles, and the river sometimes, after traversing 25 or 30 m., is brought within a mile or less of the place it had before passed. In heavy floods the water occasionally bursts through the tongue of land, and form what is called a "cut-off," which may become a new and permanent channel. The height of the banks and the great depth of the river bed check the frequent formation of these cut-offs, and attempts to produce them artificially have often failed, especially when the soil is a tough blue clay, which is not readily worn away by flowing water. This was the case at Bayou Sara, where in 1845 an excavation intended to turn the river was made, by which a circuit of 25 m. would have been reduced to a cut of one mile; and also at Vicksburg in 1862-3, where the Union army endeavored to make a cut-off out of range of the confederate guns. Semicircular lakes, which are deserted river bends, are scattered over the alluvial tract. These are inhabited by alligators, wild fowl, and gar fish, which the steamboats have nearly driven away from the main river. At high water the river overflows into these lakes. The low country around is then entirely submerged, and extensive seas spread out on either side, the river itself being marked by the clear broad band of water in the midst of the forests that appear above it. The great freshets usually occur in the spring, and are often attended with very serious consequences. Crevasses are formed in the banks and increase with the flow, which becomes so violent that the boats are occasionally carried with their crews into the intricacies of the bayous which lead the waters to the streams at the foot of the bluffs.—The lower portion of the alluvial plain, called the delta, rises from a few inches to 10 ft. only above the level of the sea, and is formed of sands and clays in horizontal layers. The delta protrudes into the gulf of Mexico far beyond the general coast line, and is slowly but imperceptibly advancing into the gulf by the shoaling caused by the deposition of the sediment brought down the river. This is mostly dispersed by the waves and currents, and distributed over the bottom of the gulf. Although the banks of the passes are sometimes observed to have advanced in the course of a few years sensibly into the gulf, these are but narrow strips of land, which may be swept away by the rush of the gulf waters driven up by storms, leaving the long coast of the delta but slightly changed. The old French maps of the early part of the last century still very cor-

...rectly represent many of the mud banks and channels or bayous around the Balize, which is the station of the pilots at the mouth of the river. Here only; for a distance of 100 m. from the gulf, is the river seriously obstructed by bars. Over these the depth of water is sometimes only 15 ft.; but this is very changeable, as the channels are shifted by the floods in the river and the gulf storms. These bars are composed of blue clay mud, through which vessels drawing 2 or 3 ft. more water than the actual depth can be taken by steam tugs. Great efforts have been made by the government to remove these obstructions by dredging, and the depth of water has been increased thereby to 21 ft.; but owing to the difficulty of maintaining such a great depth with dredges, congress has appointed a board of engineers to investigate the subject and report a plan.—The sediment of the lower Mississippi is chiefly a fine clayey matter, so universally suspended in the water as to give it a thick muddy appearance. The Upper Mississippi is clear, but the Missouri pours into it a vast amount of whitish muddy matter, which renders the water so turbid that at St. Louis one cannot see through a tumbler filled with it. This, however, does not prevent its being generally used for drinking, and for culinary purposes. The Ohio adds to it a greenish current, and the Arkansas and Red rivers pour in the red ochreous sediment already referred to; while the Mississippi itself excavates its alluvial plain and sweeps down, intermingled with the rest, vast quantities of vegetable soil that falls in the banks of the river. The coarser pebbles and sands accumulate in the bends and eddies, forming bars, and the lighter materials are deposited in the gulf of Mexico. According to the report of Capt. (now Gen.) Humphreys and Lient. (now Gen.) Abbot, a comparison of the results of many observations during a long period leads to the belief that the weight of the sediment of the Mississippi is $\frac{7}{10}$ that of the water, and its bulk $\frac{5}{6}$; and if the mean annual discharge of the river be assumed to be 12,500,000,000 cubic feet, it follows that 812,500,000,000 pounds of sedimentary matter, constituting one square mile of deposit 241 ft. in depth, are yearly transported to the gulf. In addition to the amount held in suspension, the Mississippi pushes along large quantities of earthy matter. No exact measurement of this can be made, but from the yearly rate of progress of the bars into the gulf, it appears to be about 750,000,000 cubic feet, which would cover a square mile about 27 ft. deep. The total yearly contributions from the river to the gulf amount then to a prism 285 ft. high, with a base of one square mile.—The uniformity of width of the Mississippi is very remarkable. At New Orleans it is about 3,000 ft. wide, and from this it varies little for a distance of nearly 2,000 m., except that in the bends it swells out to 1 or even 14 m. The junction of its principal branches produces no increase in the width. The depth is very variable, sometimes reaching 150 ft., but the maximum is more commonly from 120 to 130 ft. The mean depth at high-water mark is about the same at Carrollton and at Natchez, 300 m. further up. A section of the river at Carrollton, made at high-water mark in 1858, comprises 184,000 square feet, and at Natchez 221,000. The mean rate of descent varies at low water from 005 of a foot per mile at the head of the passes, to 575 of a foot at Cairo, and in high-water of 115 of a foot to 497 of a foot per mile. The velocity varies at Carrollton from 1.45 to 2.61 m. per hour, according to the stage of the water and the direction of the wind.—The Mississippi, like the other great rivers of the west, is continually gathering into its current numbers of trees, as the banks upon which they grow are undermined. They are frequently left in the main channels, their roots fixed to the bottom, and their tops pointing downstream. In this condition they are known as snags and sawyers, and present to boats ascending the river, especially at night, a most dangerous obstruction. But continual care is now given to the removal of these obstructions. The accumulations of the drift materials in the arms of the river have sometimes been so great as to bridge these over and extend for miles up the current. The obstruction is then known by the name of raft. From about the year 1778 such an accumulation had been gathering in the Atchafalaya, until in 1816 it had extended to full 10 m. in length, over 600 ft. in width and 2 ft. and 40 in depth. Though rising and falling with the water, it afforded a soil for the growth of bushes and of trees, some of which reached the height of 60 ft. In 1835 the state of Louisiana took measures to have it removed, and this was finally accomplished at a heavy cost in the course of four years. The Red river raft is still more famous for the large sums which have been appropriated by congress to effect its removal, the work upon which has been carried on with great success of late years, and is now almost completed. The appropriations made from time to time by congress for the Mississippi river comprise the following items:

For a full statement of measurements, all the phenomena, physical elements, and laws relating to this great river, see the "Report upon the Physics and Hydraulics of the Mississippi River," prepared by Capt. A. A. Humphreys and Lient. H. L. Abbot, U. S. army (4to, Philadelphia, 1861), and also the official reports of the chief of engineers to the war department.—The first European explorer
of the Mississippi valley was De Soto, who with his party reached the river in June, 1541, as is supposed not far below the site of Helena in Arkansas (See De Soto). In 1673 Marquette and Joliet descended the river to within three days' journey of its mouth. La Salle in 1682 descended the river to the gulf of Mexico, and took possession of the country in the name of the king of France. About the year 1699 Iberville built a fort upon the banks of the river, and in 1708 the settlement of St. Peter's was made upon the Yazoo branch. New Orleans was laid out in 1718, and levees were immediately commenced, which were completed in front of the city ten years afterward. At that time the levee system of lower Louisiana was fully established.

MISSOLONGHI, or Mesolonghi, a town of Greece, capital of the united monarchy of Acaenia and Etolia, 24 m. W. of Lepanto, on the N. side of the gulf of Patras; pop. about 6,000. It stands in a level plain 18 m. long and 4 m. broad, watered by the Acheous and Evenus, and extending from the base of Mt. Aracynthus to the gulf. The walls are washed by the sea, but the water is so shallow that nothing larger than a small fishing boat can approach nearer than 4 or 5 m. Missolonghi is the most important strategical point of western Greece, and is famous for the sieges it has sustained. In 1804 it fell under the dominion of Ali Pasha. In 1821 it joined in the revolt against the Turks, and on Nov. 5 Mavrocordato and Marco Bozzaris threw themselves with 400 men into the place, which was almost deserted and scarcely defensible, the fortifications consisting only of a low and ruinous wall, without bastions, and a small ditch in many places filled with rubbish. With only 14 old guns and scanty ammunition, Mavrocordato made a brilliant defence for more than two months against a Turkish army of 14,000 m. Nov. the Greeks succeeded in throwing in reinforcements by sea, and the Turks were compelled to raise the siege, Jan. 6, 1823. The town was then fortified under the direction of English officers, at the expense of an Englishman named Murray, and became one of the strongest places in Greece. From September to December, 1823, Missolonghi was blockaded for 59 days by the Turks, who besieged the neighboring Anatolic, and was defended by Constantine Bozzaris, until relieved by Mavrocordato. Lord Byron reached Missolonghi Jan. 5, 1824, and died there April 19. The last and greatest siege of Missolonghi began in April, 1825, when Reshid Pasha invested it with a large army, which was reinforced in July by the arrival of a powerful fleet, and in January, 1826, by Ibrahim Pasha with an army of 20,000 Egyptians. The garrison of 5,000 Greeks, commanded by Noto Bozzaris, made a desperate defence, repulsing repeated assaults, and, though suffering terribly from want of provisions, refused to capitulate, notwithstanding repeated offers of the most favorable terms. When continual bombardment had reduced the town to a heap of ruins and the last of their food had been consumed, at midnight of April 22, 1826, the garrison, placing the woman in the centre, salied forth in a body, and cutting their way through the Turkish camp gained the mountains, to the number of about 2,000. Those who were too feeble to join in the sortie assembled in a large mill which was used as a powder magazine, and when the Turks entered the town blew themselves up together with a large number of the enemy. The town has been rebuilt of late years, but the fortifications are decayed. Marco Bozzaris is buried here, and a statue in white marble, presented in 1855 by the French sculptor David, has been erected over his grave. Near this monument is a mound of earth with an inscription commemorative of other victims of the war. Byron's remains were conveyed to England, but his heart, which was deposited in a silver box in a mausoleum erected to his honor, was lost in the confusion of the sortie of 1826.

MISSOURI, a central state of the American Union, admitted to the Union Nov. 24, 1821. The 14th state under the federal constitution, situated between lat. 36° and 40° 30' N., and lon. 89° 2' and 95° 42' W.; length N. and S. 777 m.; average breadth about 244 m., varying from 208 m. in the north to 312 m. in the south; area, 65,550 sq. m., including a narrow strip between the St. Francois and Mississippi rivers, extending beyond the general body of the state 4° southward between Arkansas and Tennessee. Missouri is bounded N. by Iowa; E. by Illinois, Kentucky, and Tennessee, from which the Mississippi river divides it; S. by Arkansas; and W. by Indian territory, Kansas, and Nebraska, from which it is divided by a N. and S. line on the meridian of the mouth of Kansas river, and thence N. by the main channel of the Missouri river. The state is divided into 114 counties, viz.: Adair, Andrew, Atchison, Audrain, Barry, Barton, Bates, Benton, Bollinger, Boone, Buchanan, Butler, Caldwell, Callaway, Camden, Cape Girardeau, Carroll, Carter, Cass, Cedar, Clark, Christian, Clay, Clinton, Cole, Cooper, Crawford, Dade, Dallas, Daviess, De Kalb, Dent, Douglas, Dunklin, Franklin, Gasconade, Gentry, Greene, Grun-
of the state, on the Missouri river, 125 m. by rail W. of St. Louis; its population in 1870 was 4,420. The other important cities are Booneville, with 3,506 inhabitants in 1870; Cape Girardeau, 3,585; Hannibal, 10,125; Independence, 3,184; Kansas City, 32,260; Lexington, 4,373; Louisiana, 3,639; Macon, 3,678; St. Charles, 3,479; St. Joseph, 19,565; St. Louis, 310,864; Sedalia, 4,560; and Springfield, 5,556. The population of Missouri, according to the federal census, has been as follows:

Included in the population in 1870 were 3 Chinese and 75 Indians. Of the total population in that year, 896,947 were males and 854,948 females; 1,499,028 were of native and 222,257 of foreign birth. Of the natives, 874,906 were born in the state, 72,628 in Illinois, 51,303 in Indiana, 22,456 in Iowa, 102,661 in Kentucky, 31,805 in New York, 16,755 in North Carolina, 76,062 in Ohio, 35,584 in Pennsylvania, 70,212 in Tennessee, and 61,306 in Virginia and West Virginia. The foreign population comprised 8,443 born in British America, 6,293 in France, 112,618 in Germany, 14,314 in England, 54,983 in Ireland, 2,281 in Sweden, and 6,597 in Switzerland. The density of population was 26.94 persons to a square mile. There were 316,917 families, with an average of 5.43 persons to each, and 292,769 dwellings, with an average of 5.87 persons to each. The increase of population from 1860 to 1870 was 45.62 per cent. The number of male citizens 21 years old and upward was 385,293; persons from 5 to 18 years old, 577,803; number attending school, 29,348. There were 146,771 persons 10 years old and upward who could not read, and 222,411 who could not write, the latter number comprising 206,827 of native and 15,584 of foreign birth, 161,763 white, 60,622 colored, and 26 Indians, 105,767 males, and 116,636 females. Of the total population 10 years old and over, 18.45 per cent. were illiterates; number of illiterates 21 years old and over, 124,508, of whom 84,904 were white, 38,600 colored, and 15 Indians, 52,788 males, and 70,717 females. The number of paupers supported during the year ending June 1, 1870, was 2,424, at a cost of $191,171. Of the total number (1,854) receiving support June 1, 1870, 1,415 were native, of whom 1,000 were white and 325 colored, and 439 were foreigners. The number of persons convicted of crime during the year was 1,568. Of the total number (1,023) in prison June 1, 1870, 1,217 were natives and 406 foreigners; of the former 495 were white and 324 colored. The state contained 904 blind, 790 deaf and dumb, 1,263 insane, and 779 idiotic. Of the total population 10 years old and upward (1,255,568), there were engaged in all occupations 505,556; in agriculture, 263,918, of whom 86,807 were laborers, and 174,961 farmers and planters; in professional and personal services, 106,902, including 1,739 clergyman, 29,388 domestic servants, 47,492 laborers not specified, 3,452 lawyers, 3,660 physicians and surgeons, and 4,117 teachers not specified; in trade and transportation, 46,865, of whom 9,681 were clerks in stores, 6,300 draymen, hackmen, teamsters, &c., 7,710 employees of railroad companies (not clerks), and 4,757 traders and dealers not specified; and in manufactures and mechanical and mining industries, 79,850. The total number of deaths during the year was 27,982, being 1.63 per cent. of the population. There were 990 deaths from cholera infantum; 2,717 from consumption; there being 163 deaths from all causes to 1 from that disease; gripes, 719; measles, 869; pneumonia, 2,800, there being 10 deaths from all causes to 1 from that disease; smallpox, 1,084; diphtheria and scarlet fever, 1,405; intermittent and remittent fever, 1,052; enteric fever, 1,395; diarrhea, 1,300. — The Missouri river divides this state into two distinct parts. The S. part is undulating, rising into mountains as it approaches the Ozark.
Missouri

range. That portion N. of the river is more level. An extensive bottom land lies along the Missouri, commencing on the N. at Cape Girardeau and extending S. to the Arkansas river. It includes many swamps which are rendered almost impenetrable by a dense growth of trees, mostly cypress. The most extensive of these, called the Great swamp, commences a few miles S. of Cape Girardeau and passes S. to the mouth of the St. Francois, penetrating far into the state of Arkansas. More than 100 m. of this swamp are in Missouri. Within the bottom are also many lakes and lagoons; but it likewise contains many islands elevated above the reach of the highest floods. Since the earthquakes of 1811-'12 much of this tract has been inundated; but it is capable of being reclaimed, and has a very fertile soil. The highlands along the Missouri begin below Cape Girardeau, and extend to the mouth of the Missouri. Between Ste. Genevieve and the Meramec the banks, composed of solid masses of limestone, rise occasionally 360 ft. above the water. This high and undulating country extends across the entire breadth of the state, its rugged character disappearing as the Osage river is approached. This is one of the least populous sections of the state, but it is exceedingly picturesque. It has a mild, dry, and genial climate. Between the Gasconade and Osage, both of which are affluent of the Missouri, a range of low hills approaches that river, rising from 150 to 200 ft. above its mean level. They are thinly wooded, and constitute the northernmost offset of the Ozark mountains, a region of which the undulating country on the east may be considered as the lowest portion. This elevated tract covers more than half of that portion of the state S. of the Missouri. The surface is extremely broken and hilly; the hills, which rise from 500 to more than 1,000 ft. above their bases, are exceedingly numerous, but do not form continuous ranges, being divided into knobs and swells with rounded summits, and presenting perpendicular cliffs and abrupt precipices of sandstone. The soil covering them is generally shallow, and overgrown almost exclusively with oak, and in the S. counties with pine and cedar. West of this region the country, especially the basin of the Osage, is chiefly a rolling prairie, diversified with forests of stunted timber; and to the north, along both sides of the Missouri, extends a rich alluvial bottom. In the country N. of the Missouri, which comprehends about one third of the state, the surface is generally rolling or level. The bottoms along the Missouri and Mississippi are remarkably fertile. Between these rivers the country is much diversified by the broad valleys of their subsidiary streams, and intervening tracts of undulating upland which are united with the valleys by gentle slopes. The woodlands occur only on the margins of the watercourses, and the uplands are extensive prairies completely destitute of timber. These prairies occupy at least nine tenths of the whole region, and comprehend some of the best lands of the state.—The two principal streams are the Missouri, traversing the state from the N. W. corner to the middle of its E. boundary, and the Mississippi, forming its entire E. boundary, both navigable the whole year except when blocked with ice. The Osage, the next largest stream, is navigable for small steamboats half the year. Next in importance are the St. Francois, White, Black, Current, Gasconade, Grand, and Chariton rivers, all navigable for small boats a few weeks in early summer. The other principal streams, not navigable, are Salt, Fabius, South Grand, Platte, Nodaway, Spring, Sac, Niangua, Piney, Maramee, Cuivre, and Castor rivers.—The soils of Missouri may be divided into four classes, referred each to its particular district. The first class comprises all the bottom lands and the swamps of S. E. Missouri, which latter include seven or eight counties, comprising large tracts of some of the richest lands in the world, yielding often 75 to 100 bushels of corn per acre. The S. E. counties produce fine crops of cotton. The next richest bodies of land yield 50 to 75 bushels of corn per acre on uplands, and include all N. W. Missouri, with five counties S. of Missouri river. This district is mostly underlaid by the upper coal measures, and for most farming purposes is the most desirable part of the state. The third class, or second class of upland soil, includes the remainder of N. and the border counties in S. W. Missouri. In these counties 50 to 50 bushels of corn per acre are produced, and in the east they give a larger yield of wheat per acre than any others of the state. The poorest class of soils is found on all the hills of southern Missouri, where the yield is rarely over 20 to 40 bushels of corn per acre. This part of the state is 1,200 to 1,500 ft. above the sea, and chiefly underlaid by primordial sandstones and magnesian limestones, with occasional porphyry or marble. Here the hills sometimes rise 300 to 400 ft. above the unaltered magnesian limestones, but their tops are probably not more than 1,500 ft. above the sea. While N. and W. Missouri has a gently undulating or rolling surface, with hills not often over 50 ft., and distant ridges 250 ft. high, in S. Missouri the stream channels have cut out their valleys 200 to 300 ft. below the hilltops, and often 400 ft. below the tops of distant ridges. Where the main streams are distant, the country spreads out into a flat table land. South of the main Ozark ridge, where the hills are covered with either sandstone or chert, are extensive pine forests. The streams that traverse this portion of the state are clear, cool, and swift-running, and afford excellent water power. S. E. Missouri is heavily timbered, especially the swamp counties, which contain heavy forests of walnut, oak, cypress, poplar, gum, and sycamore. N. and W. Missouri is chiefly prairie, the timber being confined to narrow belts along the streams. The
prairies afford excellent pasturage, and where they are grazed down a fine growth of blue grass takes the place of the original wild grass.

The geological formations include the coal measures, 1,350 ft.; lower carboniferous, including Chester group, 300 ft.; ferruginous sandstone, 100 ft.; St. Louis limestone, 250 ft.; Keokuk group, 200 ft.; Burlington group, 300 ft.; and Chouteau group, 230 ft. The Devonian is represented by the Hamilton and Oronaga, 100 ft.; the upper Silurian by the Oriskany, 50 ft., Delthyris shale, 350 ft., Niagara group, 225 ft., and Cape Girardeau lime-

stone, 50 ft. The lower Silurian includes the Cincinnati group, 100 ft., Trenton and Black river limestone, 400 ft., and magnesian limestone series, about 1,500 ft.; the latter includes 300 to 400 ft. of sandstone excellent for glass making. The southern part of Missouri, including the Ozark range and most of the state S. of the Missouri and Osage rivers, excepting the two western tiers of counties, is from 1,000 to 1,400 ft. above the sea, and includes lower Silurian rocks, flanked by lower carbon-
iferous. On the W. flank, near the state line, the country is not often over 800 ft. above the sea. On the W. and N. flank of this high-
land the coal measures commence. On the S. side of the Missouri river are found the middle and lower coal, not over 800 or 900 ft. above the sea. In N. Missouri the same formations are about 800 to 1,000 ft. above the sea. The elevation of the eastern and southern outcrop of the upper coal measures, near the base, is 875 to 890 ft. Toward the northern part of the state the upper measures are more elevated, and may reach from 1,000 to 1,100 ft. above the sea. The coal measures being composed of alternations of shales, sandstones, and lime-
stones, their topography is such as would result from decomposition of such rocks. In no place has any limestone been observed of greater thickness than 30 ft., and the sand-
stones often pass into shales; so the topography of the coal formations is nowhere very rugged. Along the line of outcrop of the limestones are sometimes seen steep and rugged hillsides, occurring from Cass county on the south, through Jackson, Platte, Clay, Ray, Caldwell, Daviess, Gentry, Worth, and Harrison counties. N. and W. of this are the upper measures, in-
cluding alternations of thick and thin strata of limestone, with sandstones, shales, and clays; the resultant being the undulating and roll-

ring portion of N. W. Missouri. The Missouri bluffs, in the region of the upper coal measures, attain an elevation of 250 to 380 ft. above the Missouri bottoms, and the inland ridges are but little higher. The summits of the highest ridges in Nodaway county, above One Hundred and Two and Platte rivers, are but little over 200 ft., and the bluffs along the streams are in no place over 50 ft. high. On North Grand river the immediate bluffs measure from 30 to 120 ft. within the upper coal district. Lower down stream, in the middle and lower coal regions, the hills recede and become lower. Near the base of the upper coal series, it is often 200 to 250 ft. from the valleys to the top of remote ridges. In the lower and middle coal measures are great thicknesses of sand-
stones and shales, and long gentle slopes are found with bluffs on the streams 25 to 50 ft. high, rising to 100 ft. at a half mile to a mile. When the middle coal measures approach the Missouri river its bluffs vary in height from 100 to 165 ft. Another important character-

istic is peculiar, especially near the junction of the upper and middle coal measures, and sometimes to the lower measures. The sand-
stones are very much denuded, leaving isolated mounds generally 80 to 100 ft. and sometimes 140 ft. high, rising by very long slopes above the lower plains. These mounds are generally capped with limestone, which has preserved them from entire destruction. They are common throughout the lower coal district of S. W. Missouri, with sometimes intervening val-
leys 10 to 15 m. wide. The mounds have a circular base, sometimes elongated N. and S. This is particularly observable in a range trending S. along the W. line of Bates, Ver-

non, and Barton counties. From a distance these mounds appear like low mountain ranges. Aside from the mounds, the surface of the country is gently undulating and rolling. The Missouri coal field comprises an area of about 23,100 sq. m., including 160 sq. m. in St. Louis county, 8 in St. Charles, a few outliers in Lin-

coln and Warren, the remainder in N., W., and S. W. Missouri. In this area are included 8,400 sq. m. of upper or barren measures, 2,000 of exposed middle, and 12,700 of exposed lower measures. The southern and eastern boundary of the lower coal measures is as fol-

lows: entering the state about midway the west line of Jasper county, thence extending northeastwardly through Jasper, Barton, Dade, Cedar, St. Clair, Henry, Benton, Pettis, Saline, Howard, Boone, Callaway, Audrain, Montgom-
ery, Ralls, Monroe, Shelby, Knox, Lewis, and Clark counties. The aggregate thickness of the upper coal measures is 1,917 ft., in-
cluding only about 4 ft. of coal, in which are two seams 1 ft. thick, with lesser streaks. The middle coal measures include a total thickness of about 324 ft., in which are embraced about 8 ft. of coal, including two workable seams of 21 and 24 in., one which varies from 1 ft. to 8 ft., and six seams too thin to work. The lower measures include from 250 to 300 ft., embracing about five workable seams of coal, varying in thickness from 1½ to 4½ ft., and thin seams from 6 to 11 in. thick, with lesser seams and streaks; in all, 13½ ft. of coal. Missouri has therefore nearly 2,000 ft. of coal measures, with a total aggregate of 24 ft. 6 in. of coal. All beds over 18 in. thick are estimated as workable. The estimated area, where such may be reached within 200 ft. from the surface, is about 7,000 sq. m. The drift for-

mation spreads over the whole of N. Missouri,
and is limited in its southern extension by the Missouri river, with the exception of a few outliers just south of the river. In some counties it is over 100 ft. thick, and where it consists chiefly of sand and borders the country is hilly and rolling, with occasional chalybeate springs. Where blue clay is more abundant, we find a flat country. Missouri contains valuable lead and iron deposits. (See Iron Mountain, Iron Ore, and Lead.) A geological survey of Missouri is now (1875) in progress, under the direction of the state geologist, G. C. Broadhead.—The climate is in some respects extreme. The winters are sometimes long and severe, the summers often hot; and sudden and frequent changes of temperature occur. The mean annual temperature at St. Louis (lat. 39° 37', lon. 90° 16') in 1872 was 55.1°, and the total rainfall 31.5 inches. The prevailing wind was southerly, and the annual mean, as shown by the barometer, was 30.017. The mean temperature for the different months was: January, 28.3°; February, 32.4°; March, 39.1°; April, 57.5°; May, 67.4°; June, 76.9°; July, 79°; August, 74.9°; September, 69.6°; October, 60.5°; November, 40.2°; December, 30.5°. The greatest amount of rainfall, 5.97 inches, was in May.—Maize, wheat, oats, and tobacco form the staple productions. Cotton, hemp, and flax are cultivated to some extent in the southern counties. The peach, nectarine, apple, and pear are cultivated, and the wild grape abounds. Grapes are extensively cultivated in several counties, and large quantities of wine are annually produced. The prairies form excellent pasture lands, and the bottoms furnish canes and rushes for winter fodder. Sheep farming is also successfully and extensively pursued, and swine are very numerous, being readily raised in the forests. Elk are occasionally found in the timbered forests of the southeast; deer are still met with even in the partially timbered sections; and many fur-bearing animals in the unsettled parts, but too few to be profitable to the hunter. According to the federal census, there were in the state in 1860 92,792 farms with an average of 215 acres, and in 1870 148,328 with an average of 146 acres. In the former year the land in farms comprised 6,246,871 acres of improved and 13,737,939 of unimproved land, and in 1870 9,130,915 acres of improved and 12,576,605 of unimproved, including 8,905,229 of woodland and 3,611,376 of other unimproved land. In 1870 10,113 farms contained from 3 to 10 acres, 17,431 between 10 and 20, 55,987 between 20 and 50, 38,595 between 50 and 100, 24,898 between 100 and 500, 514 between 500 and 1,000, and 98 over 1,000 acres. The cash value of farms was $81,716,576; of farming implements and machinery, $4,456,633; wages paid during the year, including value of board, $10,326,794; estimated value of all farm productions, including betterments and additions to stock, $73,197,933; of orchard products, $71,019; of produce of market gardens, $61,738; of forest products, $39,975; of home manufactures, $505,295; of animals slaughtered or sold for slaughter, $4,090,819; of all live stock, $259,840,238. The productions were 1,093,905 bushels of spring and 13,222,021 of winter wheat, 550,552 of rye, 66,034,757 of Indian corn, 16,878,313 of oats, 269,240 of barley, 36,352 of buckwheat, 43,986 of peas and beans, 4,238,361 of Irish and 241,253 of sweet potatoes, 2,494 of clover, 12,246 of grass, and 10,391 of flax seed, 615,611 tons of hay and 2,816 of hemp, 1,246 bales of cotton, 12,320,483 lbs. of tobacco, 3,649,390 of wool, 14,455,223 of butter, 204,090 of cheese, 19,297 of hops, 16,013 of flax, 110,980 of maple sugar, 1,159,444 of honey, 35,248 of wax, 226,173 gallons of wine, 957,704 of milk sold, 1,730,171 of sorgum and 16,317 of maple molasses. Besides 543,822 horses and 1,269,065 neat cattle not on farms, there were on farms 492,969 horses, 111,502 mules and asses, 398,515 milk cows, 65,825 working oxen, 689,355 other cattle, 1,352,001 sheep, and 2,306,430 swine. Missouri produced in 1870, according to the census, more Indian corn than any other state except Illinois, Iowa, and Ohio, more wine than any other except California, and ranked after Kentucky, Virginia, Tennessee, Ohio, and Maryland in the yield of tobacco; it contained more mules and asses than any other, and more swine than any other except Illinois; next to Texas and Kentucky the highest number of working oxen, and excepting Texas and Illinois the most cattle. The reported production of cereals in 1873 was: corn, 70,846,000 bushels; wheat, 10,927,000; rye, 446,000; oats, 15,670,000; and barley, 266,000.—The great industrial resources of Missouri, its abundant water power, and the enterprise of its citizens have placed it in the first rank of manufacturing states. According to the census of 1870, it ranked next to New York, Pennsylvania, Massachusetts, and Ohio in the value of products, while besides those states only Connecticut and Illinois surpassed it in the amount of capital invested in manufactures. The general condition of the manufacturing industry in 1870, as compared with that of 1860, is shown in the following table:

| Year | Number of establishments | Steam engines, number | Horse power | Water wheels, number | Horse power | Hands employed, total | " " males above 16 | " " females above 15 | Capital investments | Wages | Valuation of improvements and machinery | " " of products |
|------|--------------------------|----------------------|------------|---------------------|------------|---------------------|-------------------|-------------------|-------------------|-------|---------------------------------------|----------------
| 1860 | 3,157                    | 11,871               | 1,388      | 4,519               | 3,888      | 6,644               | 62,534           | 50,504            | 1,159,444         | 58,057,244      | $81,683,445          | $141,218,499    |
| 1870 | 4,165                    | 19,063               | 5,935      | 6,644               | 62,534     | 50,504             | 3,584            | 5,560             | 1,159,444         | 58,057,244      | $81,683,445          | $141,218,499    |

Not included in the statement for 1870 is the mining industry, the products of which were valued at $3,472,513, including bituminous coal worth $2,011,820; iron ore, $491,498;
The number of establishments was 1,422, employing 8,042 hands, and having a capital of $8,458,250. Missouri in 1870 ranked first in the production of bags other than paper, animal oil, paints, and saddlery and harness, and also in bridge building; second in the manufacture of tobacco, New York being first; and third in the production of bread and crackers, brick, malt liquors, and patent medicines. There were 1,258,351 lbs. of leaf tobacco, valued at $3,725,747, besides other materials worth $371,436, used in producing 6,735,562 lbs. of chewing tobacco, valued at 8,209,593, 930,988 lbs. of smoking tobacco, worth $1,967,918, and 228,900 lbs. of snuff, valued at $154,000. Besides this, $817,195 worth of materials were used in the manufacture of 47,157 cigars, valued at $2,084,098. The relation of the state to the United States in those industries in which Missouri ranked first is shown in the following statement of the value of products:

Pork packing is also a prominent industry of the state. During the season of 1872-3 a greater number of hogs were packed in Missouri than in any other state except Illinois, while in 1879-80 it ranked after Illinois and Ohio. The number packed in the former season was 890,679, and in the latter 755,868, of an average gross weight of 250 lbs., the aggregate cost of which was $8,221,060. The total product of lard in 1873-4 was 26,153,601 lbs. The great centre of this industry is St. Louis, where 463,703 hogs were packed; Kansas City ranked next, 140,948. The most important industries of the state, as reported by the census of 1870, are shown in the following table:
City are United States ports of delivery, belonging to the district of Louisiana. In 1873, 314 vessels, of 131,087 tons, were registered, licensed, and licensed at St. Louis, and of 1,447 tons, at St. Joseph; 155, of 81,842 tons, were steamers. At St. Louis 24 vessels, of 7,756 tons, were built in 1873.—Missouri had 28 m. of railroad in 1853, and 817, in 1860. The increase of mileage was small up to 1866, when the whole number of miles was 925. In 1870 there were 2,000 m.; in 1871, 2,560; in 1872, 2,678; in 1873, 2,858; and in 1874, 2,985 m. of main track and branches. The total capital stock in 1873 was stated up at $74,440,242, and the average cost of the railroads per mile at $90,933. The total receipts amounted to $12,163,906, of which about 68 per cent. was freight and 32 per cent. from passengers. The operating expenses were $7,864,314, and the net earnings $4,322,694; dividends paid, $250,000. The railroads were valued for taxation at $24,231,330. The aid granted by the state for building them amounts to $16,762,-904, and by counties and cities to $28,570,000, making a total of $46,338,904. The railroads in operation in 1874, with their termini and lengths, are indicated in the following statement:

The number of national banks in operation Nov. 1, 1873, was 33, having a paid-in capital of $8,153,500 and an outstanding circulation of $2,906,379; circulation per capita, $8.43; ratio of circulation to wealth, 0.54 cent.; to bank capital, 64.3 per cent. There were in St. Louis 7 banks with a circulation of $1,763,150.—The constitution grants the elective franchise to every male citizen of the United States, and to every foreigner who has declared his intention to become a citizen, who has attained the age of 21 years, and resided in the state one year next preceding his registration as a voter, and during the last 60 days of that period in the place of voting. After Jan. 1, 1876, every person who was not a qualified voter prior to that time must also be able to read and write as a qualification for voting. The general elections are held biennially (even years) on the Tuesday next after the first Monday in November. The legislature is limited by the constitution to 34 senators, elected for four years (one half every two years), and 200 representatives, chosen for two years. The present number (1875) is 34 senators and 181 representatives. New apportionments are to be made immediately after every national census, and also after each state census, which the constitution provides for being taken in 1875 and every ten years thereafter. The sessions of the legislature are biennial, be-
ginning on the first Wednesday of January in odd years. Members of the legislature must be white males, and must have paid a state and county tax. The governor is elected for two years, and is not eligible to that office for more than four years in six. His salary is $6,000 per annum. A majority of each house of the legislature is sufficient to pass a bill over the executive veto. The other state officers, who are elected for the same term as the governor, are a lieutenant governor (who receives $7 a day during the session of the general assembly), secretary of state, auditor, treasurer (each of whom receives $3,000 a year), and attorney general. The constitution declares colored citizens ineligible to the above named state offices and also as members of the legislature. The supreme court, consisting of five judges elected by the people for six years, holds two annual sessions at St. Louis, at Jefferson City, and at St. Joseph. The court has power to issue all writs necessary to execute its duties, and it issues remedial writs. There are 29 circuit courts, each having one judge elected for six years, except that for St. Louis, which has five judges. They generally hold two sessions a year. Besides these there are county courts of three justices in each county, and justices of the peace. Imprisonment for debt is prohibited by the constitution except for fines and penalties imposed for violation of law. Amendments to the constitution must be approved by a majority of the members elected to each house, and ratified by a vote of the people at the next general election. A homestead not exceeding $3,000 in value in cities of 40,000 inhabitants or more, and not exceeding $1,500 in smaller cities and in the country, is exempt from levy on execution. The real estate of a married woman is not liable for the debts of the husband. The grounds of divorce are impotence, desertion for a year, adultery, conviction of felony or infamous crime, habitual drunkenness for a year, cruelties or indignities that render life intolerable, the husband becoming a vagrant, and pregnancy by another than the husband without his knowledge at the time of the marriage. Missouri is represented in congress by two senators and 13 representatives, and has therefore 15 votes in the electoral college. The bonded debt of the state on Jan. 1, 1873, and the purposes for which the bonds were issued, were as follows:

Total: $20,839,000

The total receipts into the treasury during the year ending Jan. 1, 1875, were $3,307,419, while the disbursements on warrants amounted to $3,434,782. The balance in the treasury was $566,215. The constitution provides that an annual tax of 15 per cent. shall be levied upon the gross receipts of the Pacific, North Missouri, and St. Louis and Iron Mountain railroads for the payment of the principal and interest of the state bonds received by those companies; also a tax of one quarter of one per cent. on all real and personal taxable property for the payment of that part of the state debt which is not provided for by the receipt of these funds. The total tax collected during the fiscal year 1875 amounted to $2,727,000. The constitution has provided for the management of the insane, and the insane asylum at St. Louis is free from all taxation.

In 1875 there were 335 in the asylum. The insane asylum at St. Louis is a county institution, but the state appropriated $39,000 toward its support during 1873 and 1874. An additional asylum for the insane was established at St. Joseph in 1874. Deaf and dumb persons between the ages of 7 and 30 years are received free of charge for board and tuition at the state asylum. This was opened in 1851, and at the beginning of 1873 had 146 pupils and 8 instructors. The annual appropriation by the state for current expenses is $7,000, besides $2,500 to the indigent fund. St. Bridget's institute (Roman Catholic) in St. Louis, for the education of the deaf and dumb, was founded in 1860. The institution for the blind in St. Louis, opened in 1851, receives from the state an annual appropriation of $3,000, besides the salaries of officers and teachers, amounting to about $9,000. There were 100 pupils in attendance in 1874. The state penitentiary at Jefferson City has a capacity for 1,500 convicts; the number in confinement in 1874 was 1,000, including 42 females. The prisoners are employed in the manufacture of shoes, furniture, saddlery, and barrels, and in the foundry and machine shop; about 500 convicts were thus employed in 1874. The penitentiary is leased to a company, and is just becoming self-sustaining.—The constitution requires the general assembly to maintain free schools open to all persons between the ages of 5 and 21 years. Separate schools may be established for colored children, but all funds provided for the support of public schools must be appropriated in proportion to the number of children without regard to color. Certain lands and other sources of revenue are set apart for a permanent school fund, and in case the income of such fund is insufficient to sustain a free school
at least four months in every year in each school district, the general assembly may raise the necessary amount by a local tax. The permanent school fund on Jan. 1, 1875, amounted to $2,924,954, the income of which, with 25 per cent of the state revenue, is distributed annually according to the number of pupils enumerated. The amount thus distributed March 31, 1874, was $410,269. The legal school age is from 5 to 21. The general assembly is empowered to provide for compulsory education. 

The supervision of public instruction is vested by the constitution in a board of education, consisting of a superintendent of public schools, elected by the people for four years, and the secretary of state and attorney general. 

A state university, "with departments for instruction in teaching, in agriculture, and in natural science," is made a part of the free public school system of the state. Appropriations of any public fund for sectarian education by the state, county, or any municipal corporation, are prohibited by the constitution. The most important statistics of the public schools of the state for 1873 are thus reported by the state superintendent:

| Number of persons between 5 and 21 years of age | 705,812 |
| White males | 394,046 |
| " females | 314,044 |
| Colored males | 20,203 |
| " females | 17,652 |
| Number between the ages of 5 and 16 years | 453,249 |
| " of colored persons | 928 |
| Number of school districts | 7,453 |
| " of school houses | 7,294 |
| " of private schools | 661 |
| " of normal schools | 5 |
| Number enrolled in public schools | 721,440 |
| " in private schools | 38,325 |
| " teachers | 1,329 |
| Daily average attendance in public schools | 210,092 |
| Number of teachers (male 6,251, female 8,500) | 9,071 |
| Average monthly wages, male | $49.87 |
| " female | $30.36 |
| Total income for school purposes | $2,117,606 |
| From state fund, including 25 per cent state revenue | $232,461 |
| From county | $1,161,028 |
| From township fund | $117,223 |
| From taxation | $1,198,450 |
| Total expenditures | $1,686,025 |
| Teachers' wages | $1,125,605 |
| Buildings and grounds | $255,028 |
| Rent of rooms and repairs | $44,515 |
| Fuel and contingencies | $67,857 |
| Furniture and apparatus | $65,882 |
| Balance of moneys unaccounted for | $47,300 |
| Total valuation of school property | $5,744,506 |
| Cost of education per scholar, based on enumeration | $3.00 |
| Cost of education per scholar, based on attendance or enrollment | $5.70 |

There are six normal schools, supported at public expense and without charge for tuition, with an aggregate capacity for upward of 2,800 pupils, viz.: the normal college connected with the state university, with accommodations for 150 students; the city normal school in St. Louis, 150; the North Missouri school, at Kirksville, 700; the South Missouri, at Warrensburg, 600; the Southeast Missouri, at Cape Girardeau, 500; and the normal department of Lincoln institute, at Jefferson City, 200. The condition of these institutions in 1873-'4 is shown in the following statement:

The normal schools are established upon a broad and liberal basis. The North Missouri and South Missouri schools have been erected at a cost of about $150,000 and $200,000 respectively. The complete course embraces four years. The normal department of Lincoln institute is for the training of colored teachers, while that in St. Louis is a city institution, though open to applicants from all parts of the state. The law requires two teachers' institutes to be held in each county every year. — The state university, organized in 1840, is at Columbia, near the centre of the state. It has received Missouri's portion of the national grant of land made by congress in 1862 for the establishment of colleges of agriculture and the mechanical arts. Its government is vested in a board of 24 curators, who are appointed by the governor with the consent of the senate, and who appoint the president and instructors. There is also a board of five visitors, who are required to examine into the condition of the university at least once a year. The plan of the institution embraces the college proper; the normal school, opened in 1868; agricultural and mechanical college, 1870; school of mines and metallurgy at Rolla, 1871; college of law, 1872; medical college, 1873; and department of analytical and applied chemistry, 1873. It is expected that other departments relating to the mechanic arts, the fine arts, engineering, and architecture and construction will be organized. The total number of students in attendance during the year 1873-'4 was 553, including 5 resident graduates, 176 in the college proper, 216 in the preparatory department, 107 in the school of mines, 34 in the law, and 15 in the medical school. The whole number of instructors was 29. The university is open to women on the same terms as to men. The scientific department of Washington university in St. Louis was opened in 1857, and the college in 1859. It now embraces: 1, the academy, a preparatory department; 2, Mary institute, a seminary for girls; 3, the college; 4, the polytechnic department; 5, the law school. In 1873-'4 the number of instructors in all departments was 22, and of pupils 908. The colleges and professional schools of the state are represented in the following statement for 1872-'4:
The leading institutions for the advanced instruction of women are the Ursuline academy, Mary institute, and academy of the Visitation, in St. Louis; Christian college and Stephen's female college, Columbia; Howard female college, Fayette; Independence female college, Independence; St. Teresa's academy, Kansas City; Liberty female college, Liberty; English female college, Palmyra; and Lindenwood college for young ladies, St. Charles. The oldest of these are the academy of the Visitation, organized in 1838, and Ursuline academy, opened in 1848, both Roman Catholic. Nine of these institutions report an aggregate of 1,136 pupils, of whom 807 were in the collegiate and 329 in preparatory studies, and 97 instructors, including 11 males. St. Louis has four commercial and business colleges, and there is one in St. Joseph and one in Kansas City. According to the census of 1870, the total number of educational institutions in Missouri was 6,750, having 9,028 teachers, of whom 3,871 were females, and 370,387 pupils. The total income of the whole was $4,340,865, of which $375,567 was from endowment, $3,067,449 from taxation and public funds, and $1,215,789 from tuition and other sources. Besides the 5,966 public schools, having 7,382 teachers, there were 37 colleges with 261 teachers and 6,067 students, 45 academies with 333 teachers and 5,081 pupils, and 566 private schools with 770 teachers and 26,816 pupils. The total number of libraries in the state was 5,845, having 1,065,658 volumes; 3,903 with 566,645 volumes were private, and 1,742 with 498,916 volumes other than private. Of the latter there was 1 state library, with 12,000 volumes; 11 town, city, county, 8,07; 125 court and law, 35,104; 50 school, college, &c., 4,425; 1,183 Sabbath school, 188,593; 245 church, 96,845; and 28 circulating, 112,450. The largest libraries in the state are the St. Louis mercantile, 45,000 volumes; St. Louis university, 25,000; public school library of St. Louis, 36,000; and college of the Christian Brothers, 10,000. The total number of newspapers and periodicals was 279, having an aggregate circulation of 322,580, and issuing annually 47,980,429 copies. There were 21 daily, with a circulation of 86,655; 5 tri-weekly, 13,800; 252 weekly, 342,361; 8 semi-monthly, 22,000; 33 monthly, 53,650; and 1 annual, 1,500. In 1874 there were reported 24 daily, 5 tri-weekly, 1 semi-weekly, 284 weekly, 6 semi-monthly, 30 monthly, 1 bi-monthly, and 1 quarterly; total, 352. In 1870 the state contained 3,229 religious organizations, having 2,028 edifices with 691,520 sittings, and property valued at $8,700,508. The different denominations were represented as follows:

—By the grant of Louis XIV. to Crozat dated Sept. 14, 1712, "all the country drained by the waters emptying directly or indirectly into the Mississippi is included in the boundaries of Louisiana." (See Louisiana.) The states of Arkansas, Iowa, Kansas, and Nebraska were parts of the same grand division. The northern portion was called Upper Louisiana. The settlement and progress of Missouri were later and less rapid than those of the lower districts; but as early as 1720 its lead mines had attracted attention. In 1755 Ste. Genevieve, its oldest town, was founded. In 1762 France ceded to Spain the territory W. of the Mississippi, and the portion E. of that river to England. France had been despoiled of all her North American possessions. During the contest numbers of Canadian French settled in both Upper and Lower Louisiana, and a flourishing river trade sprang up between the two sections. Lands were granted liberally to the colonists, and numerous emigrants from Spain flocked into the country. In 1775 St. Louis, originally a depot for the fur trade, contained 800 inhabitants, and Ste. Genevieve about 460. At this time Spain, siding with the colonists, entered into hostilities against England. In Lower Louisiana and Florida the arms of Spain were successful; but in 1780 St. Louis was attacked by a body of English and Indians from Michilimackinac, and was only relieved by the timely arrival of Gen. Clarke from Kaskaskia. The general peace of 1783 put an end to hostilities. In the division of the Louisiana purchase in 1803, Missouri was included in the district of Louisiana, which in 1805 was erected into the territory of Louisiana, with St. Louis as the seat of its government. In 1812, on the admission of the present state of Louisiana into the Union, the name of the territory was changed to Missouri, and its government was made representative. The limits on the west were gradually extended by treaties with the Indians. In 1810 the population numbered 29,845, of whom all but about 1,500 belonging to Arkansas were settled within the present limits of Missouri. Immigration now came in rapidly from the east. In 1817 the total population had increased to 60,000, and St. Louis contained 5,000 inhabitants. In this year the assembly applied to congress for permission to frame a state constitution. The struggle to prevent the extension of slavery into the new states led to the celebrated compromise of 1820, whereby it was determined that Missouri should come into the Union as a slaveholding state, but that slavery should never be established in any states formed in the future from the lands lying N. of lat. 36° 30'. The state constitution was framed by a convention of 40 delegates convened in St. Louis, July 19, 1820; and the state was admitted by proclamation of the president, Aug. 10, 1821. From this time until the present the progress of the state in material prosperity has been rapid; immigration has been constant, and agriculture, mining, commerce, and manufactures have been expanded into vast interests. The first movement in Missouri toward secession was made on Jan. 16, 1861, when a bill was passed by the senate providing for the assembling of a state convention. This body was organized at Jefferson City on Mar. 18, and convened in St. Louis March 4. Popular feeling was opposed to secession, and the action of the convention, which adjourned without passing any measures of great importance, as well as of the legislature, was strongly in favor of the Union. Soon afterward United States troops began to assemble under command of Gen. Irarney in St. Louis, which was regarded as an important military point for operations against the insurgent states. Some minor conflicts having arisen between the federal troops and the state militia, and negotiations for the maintenance of peace having failed, a general massacre took place on June 30, and Gen. Jackson, calling into active service 50,000 of the state militia "for the purpose of repelling invasion, and for the protection of the lives, liberty, and property of the citizens." On the following day 1,500 United States troops under command of Gen. Lyon were moved from St. Louis to Jefferson City, where they arrived on the 16th. About the same time other troops were sent to Rolla. Gov. Jackson, however, with other officers of the state government, had fled from Jefferson City on the 15th and gone to Booneville, where he summoned the state troops to his support. Gen. Lyon immediately advanced upon this point, and on June 17 defeated the state troops, who subsequently retreated to Syracuse. The greater portion of the state at this time was under federal control, but hostile state troops were organized in the southwest under Gen. Price. The state convention, having been re-assembled, on July 30 declared vacant the offices of governor, lieutenant governor, and secretary of state, and filled them by appointment. The seats of the members of the legis-
lature were also declared vacant. On Aug. 1 Gov. Gamble, appointed by the convention, was inaugurated. On the 5th Gov. Jackson, at New Madrid, issued a proclamation declaring the separation of the state from the Union. Confederate forces were now assembling in large numbers in S. W. Missouri under Gen. Pillow, Hardee, McCulloch, Price, and Thompson. From Booneville Gen. Lyon's force moved to Springfield, and on Aug. 10 encountered a force of state troops and confederate soldiers from Arkansas under Gen. Price and McCulloch at Wilson's creek, near Springfield, where Gen. Lyon was killed. After the battle, the federal forces, under command of Col. Sigel, retired to Rolla. On Aug. 31 Gen. Fremont, commanding the department of the West, declared martial law throughout the state. A large federal force was now gathered at St. Louis for operation against the confederates in the S. W. part of the state. On Sept. 20 Lexington, defended by about 3,000 federal soldiers under Col. Mulligan, was surrendered after a severe conflict with a much larger army under Gen. Price. This caused Gen. Fremont, Sept. 27, to hasten from St. Louis to Jefferson City. The confederates, however, numbering about 20,000, soon retired from Lexington to Springfield and further south. The advance of Fremont in the southwest, which was attended with numerous skirmishes, was made in five divisions under Gen. Hunter, Pope, Sigel, Asboth, and McKinstry. On Nov. 2 Fremont was succeeded by Gen. Hunter. The federal forces soon after began to recede, and the confederates to advance in the same direction. On Nov. 18 Gen. Halleck arrived at St. Louis to assume command of the western department. Certain members of the legislature, friendly to the confederate cause, having obtained a quorum of that body at Neosho, on Nov. 2 passed an act ratifying an arrangement between commissioners of the state and the confederate government, by which Missouri was to become a member of the confederacy. At the beginning of 1862 nearly half of the state was held by the confederate troops; but in February a strong federal force under Gen. Curtis drove Price into Arkansas. Throughout the year the state was much disturbed by guerilla warfare. In the summer of 1863 the state convention which had been originally assembled to consider the subject of secession, and had been kept in existence by adjournments, passed an ordinance providing for the emancipation of all slaves in the state in 1864. In the autumn of 1864 Gen. Price, having again invaded Missouri, threatened St. Louis, and traversed a large part of the state, but was finally forced to retreat into Arkansas. The first election for state officers after the beginning of the war was held in November, 1864, the state having been governed during this period by officers appointed by the state convention. On Jan. 6, 1865, a convention assembled in St. Louis and framed a new constitution, which was ratified by the people in June following by a vote of 43,670 to 41,808. During the war Missouri furnished to the federal army 108,773 troops, equivalent to 86,192 for three years. The 15th amendment to the federal constitution was ratified by the legislature in 1869 by a large majority.

**MISSOURI RIVER** (i.e., Mud river), the principal tributary of the Mississippi. It properly forms one stream with that river, being much greater in length and volume than the other branch which bears that name above the mouth of the Missouri. It rises near the boundary between Montana and Idaho, among the Rocky mountains, in several small streams, the principal of which are Jefferson and Wisdom rivers (the latter rising within a mile of the head springs of Clarke's fork of the Columbia), whose sources lie between lat. 44° 20' and 45° 35' N., and lon. 112° and 114° W., uniting about lat. 45° 15', lon. 110° 30'. According to some geographers, the Missouri properly begins about 80 m. farther E., where the stream formed by the Jefferson and Wisdom, on this hypothesis retains thus far the former name, is joined by the Madison and Gallatin. The Madison, the middle and largest fork, by some considered the true source, rises in the National Park in N. W. Wyoming, near the sources of the Snake and Yellowstone. After a devious course N. from the junction of the three forks to about lat. 48°, the Missouri runs E. through Montana into Dakota, where it is joined by (lesser) White Earth River. Its general direction is S. E. thence to the Mississippi, which it joins in lat. 38° 50' 50" N., lon. 90° 14' 45" W., after separating Nebraska from Iowa, forming a small part of the dividing line between Missouri and Kansas and Nebraska, and flowing across the whole state of Missouri. Its length to the Madison fork source is 2,908 m., which added to 1,286 m., the length of the lower Mississippi, makes its whole course to the gulf 4,194 m. It has commonly been navigated as far as the mouth of the Yellowstone, on the border of Dakota and Montana, but it may be ascended by steamboats much further, to the Great falls almost at the very base of the mountains, and about 2,500 m. from the Mississippi. There is no serious obstruction to navigation below this point, though at certain seasons the water is shallow, owing to its passing through a dry and open country in its upper course, and being subject to extensive evaporation. It is generally turbid and rapid. In its lower course it is bordered by a narrow, alluvial valley of great fertility, back of which lie generally extensive prairies. At its mouth it is over half a mile wide, and in many places it is much wider. Its principal tributaries are the Yellowstone, Little Missouri, Big Cheyenne, (greater) White Earth, Niobrarah, Plate or Nebraska, Kansas, and Osage on the right, and the Milk, Dakota, Big Sioux, Little Sioux, and Grand on the left. It will thus be seen that
the Missouri receives all the great rivers which rise on the eastern declivity of the Rocky mountains, with the single exception of the Arkansas, and a large share of the waters which lie between its own bed and that of the Upper Mississippi. The area which it drains is estimated at 518,000 sq. m. The most important places on its banks are Fort Benton in Montana, Yankton in Dakota, Sioux City and Council Bluffs in Iowa, Omaha in Nebraska, Atchison and Lebanonworth in Kansas, and St. Joseph, Kansas City, Lexington, Booneville, Jefferson City, and St. Charles in Missouri. About 400 m. from its source the river passes through a narrow gorge denominated the "Gates of the Rocky mountains." It is 5½ m. long, and the perpendicular walls of rock, which rise directly from the water to the height of 4,500 ft., are only 450 ft. apart. For the first 3 m. there is but one spot where a foot-hold could be obtained between the water and the rock. The Great falls are 145 m. below this point. They are among the grandest on the continent, and consist of four cataracts, respectively of 26, 47, 19, and 87 ft. perpendicular descent, separated by rapids. The whole fall in 16½ m. is 357 ft.

**MISSOURIS,** or **Missourias,** a tribe of Indians belonging to the Dakota family, and calling themselves Nudarcha, Missouri being the name given them by the Illinois. Marquette in 1673 first heard of them as the first tribe up the river which bears their name. As allies of the Illinois they soon established friendly relations with the French, and were among the tribes who in 1712 marched to the relief of Detroit. In 1719 they entrapped and cut to pieces a Spanish expedition sent against them from Mexico. In 1720 the French under De Bourgmont established a fort on an island near the Missouris, and the great chief aided him to reach and make peace with the Comanches. He took some of the chiefs to France in 1725, and Dubois, a sergeant who had married a girl of the tribe, returned with them as command- er of the post; but the French were soon after massacred to a man. Friendly relations were afterward restored, and Missouris served in the French operations against the Chickasaws. They were opposed to the English ascendancy. Lewis and Clarke found them in 1805 reduced to a band of 300 souls, with 80 warriors, on the south side of the Platte, at war with the Omahas, Poncas, Osages, Sioux, and Kansas. Great numbers had been carried off by smallpox, and, abandoning their ancient village in a fertile plain on the Missouri below the Grand, they had sought refuge with the Ottoes, with whom they have ever since been connected. After various sales of lands by them to the government, the combined tribes were removed to the Big Blue. In 1862 they numbered 708, and in 1872 had decreased to 464. They now receive $9,000 a year, but when ten payments have been made the annuity is to be reduced to $5,000. Missions at-

**MISTAKE**

tempted by the Presbyterians, as well as all attempts at education, have proved unavailing.

**MISTAKE.** It is a fundamental principle of law that no man shall avail himself, either to establish or resist a claim, of his mistake or ignorance of law. So also in criminal law it is an ancient maxim: *Ignorantia legi nemo excitat.* The reason sometimes assigned, that the law supposes every one to be acquainted with it, is nothing more than a repetition of the rule in other words. The true reason is, the extreme danger of permitting any person to shelter himself under his ignorance of the law, or to found a right upon it. For this would be, in the words of the king's bench in England, "to hold out a premium for ignorance," and ignorance of that which it is of the utmost importance that all men should know. Hence the law distinguishes most carefully between a mistake of law and a mistake of fact; for the latter, as a general rule, is, rectified, and all mischievous consequences prevented, as far as possible; and a mistake as to the law of a foreign state or country is regarded only as a mistake of fact, because no one is under any obligation to become acquainted with a foreign law.—To this general rule there are some important qualifications; the principal one being, that no mere acknowledgment, or waiver of defence or right, made under a mistake of law, is binding. Thus, if one has a good legal defence against a promissory note, but, through ignorance or mistake of the law, supposes himself bound to pay it, and on this supposition gives a promise to pay it, the promise will not, in general, be binding upon him. In many cases also much relief is to be obtained by the construction of a contract; but this is always governed and limited by certain definite rules. It is often said by ethical writers, that a party to a contract is bound to execute the contract in the sense which he knew the other party to put upon it. This may be true always in a moral sense; but it is certainly not true in a legal sense, although courts have sometimes seemed to think it was a good rule of law. The true rule and the reason of it are easily seen. If A contracts with B in writing to sell him 100 mules, and receives the money, and B at the time, being a foreigner perhaps or for some other reason, understood that he was buying horses, all which A knew, nevertheless B could not claim horses under the contract. He could, by proving his mistake and A's knowledge of it, make out a case of fraud, and this would annul the contract, and then he could recover his money. But the reason why he could do no more is, that the law will not, under pretence of construing a contract, make a new contract for the parties. Hence, it is another way of expressing the same rule, that the actual intention of the parties to a contract shall be carried into effect, so far as it is possible to arrive at that intention by a rational construction of the words they have actually used, but no fur-
ther; for it is one of the most reasonable, safe, and well established rules, that no evidence from without a written contract shall be permitted to control or vary it. While parties are negotiating they may change their minds and vary their demands and concessions, and generally do this to some extent. But when they have finally put their terms in writing, the law supposes that these are what they have concluded upon, and that they have chosen and used the very words which express their meaning; and that whatever is not therein stated, although it may have previously passed between them, has been purposely omitted because it was not finally agreed to. It would therefore be manifestly unjust to permit evidence of any of these things to come forward and vary the written contract; and hence the rule, which is concisely expressed in the Scotch law thus: "Writing cannot be cut down or taken away by the testimony of witnesses." But while evidence must not vary, it may explain, the contract. Thus, in the most solemn deed, it may be necessary to explain the terms of the instrument, in order to show who the parties are, what the boundaries of land mean, or where it is situated. But it is a very different thing when one of the parties says that the deed contains a mistake; that the house or the field it conveys is not the house or field which it was intended to convey; and on this ground demands to hold the house or field which, as he alleges, should have been given to him. And it may be regarded as the established rule concerning mistakes, that any mistake in an instrument may be corrected by construction, if the instrument itself affords the means of correction; but not, if it can be done only by going outside of the instrument.

Courts of equity, however, have large powers to reform conveyances and contracts where by mistake in drafting them they are made to express a different intent from the one agreed upon. (See Chancery, and Equity.)

**MISTLETOE.** (Anglo-Saxon mistilitan, from mist, different, and ten, twig, as the plant is unlike the tree upon which it grows), a parasitic evergreen shrub of the family Loranthaceae. The true European mistletoe is *Viscum album*, the generic name being the Latin word for the plant as well as for bird lime. The family comprises about 30 genera of mostly tropical evergreen shrubs, all of which are parasitic, and some of which have showy flowers; a description of the less conspicuous mistletoe will give the general characters of the whole family. The genus Viscum, besides the common European one, comprises a few Asiatic species. The mistletoe is unaccustomed when young, but becomes woody when old; its branches are repeatedly forked, and form together dense tufts 1 to 2 ft. in diameter, and attached to the branches of the trees by the thickened base of its main stem; the branches break readily at the distinct joints, at each of which is borne a pair of opposite, sessile, thickish leaves, which vary from narrowly oblong to obovate, but are always entire and obtuse; the flowers are dicotious, nearly sessile in the forks of the branches; those in the male plant three to five together in a somewhat cup-shaped involucre, with short, thick, triangular petals, and the same number of stamens, which are sessile in the centre of the petals, their anthers opening by several pores; the female or pistillate plant has its flowers solitary, rarely two or three together, and consisting of four minute petals at the top of the ovary, which is one-celled, with a simple style, and in ripening forms a white, semi-transparent berry with a single seed, surrounded by an exceedingly viscid or glutinous pulp. The mistletoe extends from Sweden to the Mediterranean, and is very common in the southern and western counties of England, where it grows upon a great variety of trees; it especially affects the apple, and in the elder districts is very destructive to the trees, as when once established it continues to grow as long as there is any life in its host. It is supposed to be disseminated by birds which feed upon the berries, and that in their attempts to wipe the viscid pulp from their bills they attach the seeds to the bark of the branches. To establish the plant artificially, a small slit of the bark is raised with a knife and the seeds are placed beneath it; this is done upon the under side of a branch to hide the seed from birds. Many experiments have been made upon the germination of this plant, and it is found that, in whatever position the seed may be placed, the radicle, which in ordinary plants tends directly downward, will be directed toward the surface to which the seeds are attached, without reference to gravitation, light, or any other influence. The radicle is frequently obliged to arch itself over to reach the bark, and when it comes in contact with this its end expands to form a disk which gives it a firm hold; from this proceed roots which
penetrate the bark, and thus place the young plant in contact with that portion of the tree where nutriment is most abundant. An instance is recorded of the growth of one specimen upon another mistletoe. The plant does not grow in the north of England or in Scotland and Ireland, and nurserymen there plant the seeds upon the bark of young apple trees, and sell the trees with the mistletoe already established upon them. The superstitions and legends connected with the mistletoe are numerous; it was held in high veneration by the ancient Britons, and its collection by the druids was accompanied with great solemnity; the plant is found more rarely upon the oak than upon any other tree, hence that which grew on the oak was regarded with peculiar honor; it was cut on the sixth day after the first new moon of each year, the priest using a golden sickle; the plant was received upon a white cloth and divided among the people, who preserved the fragments as a charm to protect them from disease and every other evil. In England it is used among Christmas decorations, and during the festivities, if a gentleman discovers a lady beneath the "mistletoe bough" he has a right to a kiss: this is a very old custom which has descended from feudal times, but its real origin and significance are lost. Within recent times the mistletoe has been regarded as a valuable remedy in epilepsy and other diseases, but at present it is not employed. The chief use of the plant is for holiday decorations, for which purpose it is occasionally brought to this country; its berries were formerly used to prepare bird lime, and the leaves have been fed to sheep in times of scarcity of other forage.—The American mistletoe, which was first described as a viscum, is so different from the European that Nuttall made a new genus for it, phoradendron (Gr. φαον, a thief, and δέσμον, a tree); it differs from viscum in having both kinds of flowers in the same catkin-like, jointed spikes, and sunk in the joints; there is also a difference in the structure of the anthers. The plant has the same manner of growth, and is similar in general appearance to the European, but the leaves and stems are of a more yellowish green; the berries are white. There are several species of phoradendron, the most common being P. flavescens, which grows from New Jersey and Illinois to Texas and Mexico; there are several varieties, differing in the shape and smoothness of their leaves; it grows upon various deciduous trees, and in Texas is especially abundant on the mesquite, upon which it often grows in such quantities as to hide the proper foliage of the tree. There are half a dozen other species, all belonging to the far south and west.—Another related genus is arceuthobium, the species of which are small, much branched, leafless, and like the others parasitic. A. oxycedri is found on various coniferous trees from California to New Mexico, and further north it extends eastward to Hudson bay. In 1871 Mrs. Millington discovered in Warren co., N. Y., a minute species of arceuthobium growing upon the branches of the black spruce (abies nigra), and about the same time it was discovered by Prof. Peck of Albany. The plant is scarcely more than an inch long, but occurs in such quantities as to seriously injure the trees; it is probably a form of A. campylopodium.

MISTRAL, Frédéric, a French poet, born at Maillane, near St. Remy, Provence, Sept. 8, 1830. He studied at Lyons and Avignon, where he graduated in jurisprudence, but devoted himself to poetry in his native village. His principal work is the pastoral Provençal epic Mérie (Mireille), with a French text (Avignon, 1859; enlarged ed., 1862; English translation by H. Crichton, London, 1868, and by Harriet W. Preston, Boston, 1872), for which he received in 1861 an academical prize of 2,000 francs, and which has been set to music by Gounod as a comic opera. He published Calendan, a poem, in 1867. In September, 1868, great literary and social entertainments were given at St. Remy in honor of Provençal poetry, in which he took the most prominent part.

MITAU, or Mitau (Russ. Mitava; Lettisch, Yelgava), a town of Russia, capital of Courland, situated in a low marshy district on the Aa, 25 m. S. W. of Riga; pop. in 1867, 29,100; mostly Germans, and including about 5,000 Jews. It is well built, and contains one Reformed, one Greek, one Roman Catholic, and three Lutheran churches, three synagogues, a gymnasium with a museum of physical science and natural history, a library, and various educational and charitable institutions, besides the buildings of the local authorities. Near Mitau is a palace built by Biron on the site of the original castle, after the model of the czar's Winter palace, where Louis XVIII. resided for a long time under the name of the count de Lille. There is an extensive trade in furs, and in the Exchange, which is sent butter from the interior of Courland and Lithuania for shipment on the Aa to Riga. The nobility of Courland reside here in winter, but Mitau is especially lively about St. John's day, when transactions are closed both by the nobles and the traders.

MITCHEL, John, an Irish revolutionist, born at Dungiven, county Derry, Nov. 3, 1815. His father was a Unitarian clergyman. He graduated at Trinity college, Dublin, in 1838, studied law, and practised for six years in Newry and Bannbridge, during O'Connell's agitation. In 1845 he was called to Dublin to succeed Thomas Davis in the editorship of the "Nation." His articles were revolutionary, and for one which appeared in 1846, showing how the people could contend with the army, the "Nation" was prosecuted by government. In consequence of differences in policy he quarrelled with his partner Gavin Duffy toward the end of 1847, and soon after founded the "United Irishman," which brought him in direct collision with the government. After an existence of three
months the journal was suppressed, and its editor sentenced to expatriation for 14 years. On May 27, 1848, after two weeks' incarceration at Newgate, Mitchel was taken in irons from Dublin to Spike island (Cork harbor), where a government order was received to treat him "as a person of education and a gentleman." Taken thence in a day or two, he passed 10 months in the island of Bermuda, whence he was again deported to Australia. Here he met Smith O'Brien, Meagher, and other political associates. On July 19, 1854, Mitchel resigned his parole and escaped from the colony, landing in New York on Nov. 29. There he founded the 'Citizen,' a weekly journal, which he conducted until failing eyesight constrained him to seek a more congenial climate. He removed to Tennessee, where he established the 'Southern Citizen,' in which he advocated the reopening of the slave trade. He edited the Richmond "Examiner" during the civil war, after which he settled in New York. In July, 1874, he made a visit to Ireland, returning in October. In February, 1875, he was elected to parliament for Tipperary, though disqualified for a seat by his uncancelled sentence, and again went to Ireland. He is the author of "Hugh O'Neill," a Brown "Jail Journal" (New York, 1834). "The Last Conquest of Ireland (perhaps)?" (Dublin, 1861), and a continuation of MacGeoghegan's "History of Ireland." He has also edited the poems of Thomas Davis and James Clarence Mangan, with biographies.

MITCHEL, Ormsby Macknight, an American astronomer, born in Union co., Ky., Aug. 28, 1810, died at Beaufort, S. C., Oct. 30, 1862. At 12 years of age, with a good knowledge of Latin and Greek and the elements of mathematics, he became clerk in a store in Miami, O., and afterward removed to Lebanon, Warren co., where he had been educated. Being appointed a cadet, he earned the money that took him to West Point, which place he reached almost penniless in June, 1829. After graduating in 1829, he was acting assistant professor of mathematics for two years. From 1832 to 1834 he was a counselor at law in Cincinnati; from 1834 to 1844 professor of mathematics, philosophy, and astronomy in Cincinnati college; in 1836 and 1837 chief engineer of the Little Miami railroad. An observatory having been erected at Cincinnati chiefly through his exertions, he became its director; and in 1859 he took the direction of the Dudley observatory at Albany, retaining his connection with that at Cincinnati. In August, 1861, he was commissioned brigadier general of volunteers, and assigned to the department of the Ohio. After the occupation of Bowling Green and Nashville, he made a forced march into Alabama, fought a battle near Bridgeport at the close of April, 1862, and seized the railroad between Corinth and Chattanooga, for which he was promoted to the rank of major general. In July he was relieved of his command in the west, and in September was placed in command of the department of the South, where he was preparing for an active campaign when he died of yellow fever. He was a popular lecturer on astronomy, and scarcely less distinguished for his mechanical skill, by which he perfected a variety of astronomical apparatus, among the most important of which was that for recording right ascensions and declinations to within $10^\circ$ of a second of time. Among his discoveries are the exact period of rotation of Mars, and the companion of Antares or Cor Scorpion. He also remeasured W. Struve's double stars S. of the equator, which resulted in several interesting discoveries. He published "Planetary and Stellar Worlds," a collection of lectures, a treatise on algebra, and a "Popular Astronomy." In 1846-8 he published "The Sidereal Messenger," a periodical.

MITCHELL. I. A N. W. county of North Carolina, bordering on Tennessee, bounded S. W. by the Nolichucky river; area, about 530 sq. m.; pop. in 1870, 4,703, of whom 218 were colored. It lies between the Blue Ridge and Iron mountains. In 1867 five valuable mica mines were discovered in this county, which have since been extensively worked, and the trade has enabled the inhabitants to pay off the entire debt of the county. The chief productions in 1870 were 12,530 bushels of wheat, 6,065 of rye, 72,860 of Indian corn, 21,311 of oats, 8,485 of potatoes, 8,725 lbs. of wool, and 35,760 of butter. There were 665 horses, 1,416 milch cows, 2,207 other cattle, 5,142 sheep, and 6,889 swine. Capital, Bakersville.

MITCHELL. II. A S. W. county of Georgia, bounded N. E. by Flint river; area, about 500 sq. m.; pop. in 1870, 6,635, of whom 400 were colored. The surface is level and the soil fertile. It is traversed by the Albany division of the Atlantic and Gulf railroad. The chief productions in 1870 were 150,526 bushels of Indian corn, 26,240 of oats, 21,382 of sweet potatoes, 39,860 lbs. of butter, 4,708 bales of cotton, and 21,412 gallons of sorghum molasses. There were 2,133 milch cows, 4,121 other cattle, 2,092 sheep, and 7,186 swine. Capital, Camilla.

MITCHELL. III. A N. county of Iowa, bordering on Minnesota and intersected by the Red Cedar river and its E. fork; area, 431 sq. m.; pop. in 1870, 5,582. It is intersected by the Burlington, Cedar Rapids, and Minnesota railroad. The chief productions in 1870 were 564,894 bushels of wheat, 150,847 of Indian corn, 358,105 of oats, 33,804 of barley, 36,141 of potatoes, 8,906 lbs. of wool, 194,060 of butter, and 15,415 tons of hay. There were 2,600 horses, 2,986 milch cows, 5,685 other cattle, 2,440 sheep, and 2,003 swine; 2 manufactories of agricultural implements, 6 of carriages and wagons, 1 of iron castings, 1 of patent medicines, 1 woollen mill, 3 saw mills, and 1 flour mill. Capital, Mitchell.

MITCHELL. IV. A N. central county of Kansas, intersected by Solomon river; area, 720 sq. m.; pop. in 1870, 485. The surface is undulating, and consists mostly of fertile prairies. The chief pro-
duction in 1870 was 6,250 bushels of Indian corn. The value of live stock was $56,377.

MITCHELL, Donald Grant, an American author, born in Norwich, Conn., in April, 1822. He graduated at Yale college in 1841, travelled in Europe, studied law in New York, and in 1847 published, under the pseudonym of "Ik Marvel," "Fresh Gleanings, or a New Sheaf from the Old Fields of Continental Europe." He was in Europe in 1848, and wrote "The Battle Summer" (New York, 1849). This was succeeded by a satirical work entitled "The Lorgnette," which appeared anonymously (2 vols., 1850). In the same year appeared "The Reveries of a Bachelor," and in 1851 his "Dream Life." In 1853 he became United States consul at Venice, in 1855 returned, and has since resided on his farm of "Edgewood," near New Haven. He was for some time associate editor of the "Hearth and Home," New York, and has frequently appeared as a lecturer. His later publications are: "Fudge Doings" (2 vols., 1854); "My Farm of Edgewood" (1858); "Six Days at Edgewood" (1864); "Seven Stories, with Basement and Attic" (1864); "Doctor Johns" (2 vols., 1866); "Rural Studies" (1867); and "Pictures of Edgewood" (fol., 1869).

MITCHELL, Elisha, an American chemist, born at Washington, Litchfield co., Conn., Aug. 19, 1793, died on the Black mountains in North Carolina, June 27, 1857. He graduated at Yale college in 1813, and in 1818 became professor of mathematics in the university of North Carolina, and in 1826 of chemistry. In 1821 he was ordained a Presbyterian minister. He was for some time state surveyor. He first ascertained that the mountains of North Carolina are the highest east of the Rocky mountains. (See Black Mountains.) To settle some disputed points in regard to these heights, he ascended them in 1857, lost his way at night, fell down a precipice, and was killed.

MITCHELL, I. John Kearsley, an American physician, born at Shepherdstown, Jefferson co., Va., May 12, 1798, died in Philadelphia, April 4, 1858. He was educated in Scotland, graduated M. D. at the university of Pennsylvania in 1819, made three voyages to China as ship's surgeon, and in 1822 began to practice medicine and teach physiology in Philadelphia. In 1826 he became professor of chemistry in the Philadelphia medical institute, in 1835 in the Franklin institute, and in 1841 of the theory and practice of medicine in the Jefferson medical college. He published "Indecision, and other Poems" (Philadelphia, 1839), "On the Cryptogamous Origin of Malignous and Epidemical Fevers" (1849), and several popular scientific lectures. After his death appeared a selection from his papers entitled "Five Essays," 8vo. (1858). II. S. Weir, an American physician, son of the preceding, born in Philadelphia, Feb. 15, 1829. He graduated at Jefferson medical college in 1850. His earlier researches were chiefly in toxicology, and are especially authoritative on the venom of serpents. His later writings have been almost entirely devoted to diseases of the nervous system. He has published, with G. R. Morehouse, M. D., and W. W. Keen, M. D., "Gunshot Wounds and other Injuries of the Nerves" (Philadelphia, 1864), and "Injuries to Nerves, and their Consequences" (1871); and he has also made numerous contributions to scientific journals, including "Experimental Researches relative to Corroval and Vao, American Arrow Poisons," with W. A. Hammond, M. D. ("American Journal of Medical Sciences," 1859); "Toxicological Study of Ordeal Poisons, Sassy Bark" ("Charleston Medical and Surgical Journal," 1859); "Researches on the Venom of the Rattlesnake" ("Smithsonian Contributions to Knowledge," 1860); "Treatment of Rattlesnake Bites" ("North American Medical and Chirurgical Review," 1861); "On the Circulation in Chelonica Serpentina" ("Memoirs of the American Philosophical Society," 1862); "Arsenal Albinarinia" ("New York Medical Journal," 1857); "Antagonism of Atropia and Morphia," with Drs. Morehouse and Keen ("American Journal of the Medical Sciences," 1865); "Palsy from Peripheral Irritations" ("New York Medical Journal," 1866); "Production of Spasms from Cold to the Skin" ("American Journal of the Medical Sciences," two papers, 1867-8); and "Experimental Contributions to the Toxicology of Rattlesnake Venom" ("New York Medical Journal," 1868).

MITCHELL, Marla, an American astronomer, born in Nantucket, Aug. 1, 1818. She derived from her father, who taught a school in Nantucket, a fondness for astronomy, and by her intelligence in the use of instruments and her mathematical attainments soon became an enthusiastic cooperator in his labors. Subsequently she made many careful observations by herself, and devoted much time to the examination of nebulae and the search for comets. On Oct. 1, 1847, she discovered a telescopic comet, for which she received a gold medal from the king of Denmark. She has been employed in observations connected with the coast survey and in compiling the nautical almanac. She is a member of the American association for the advancement of science, and was the first female member of the American academy of arts and sciences. In 1865 she was appointed to the chair of astronomy in Vassar college, Poughkeepsie, N. Y.

MITCHELL, Sir Thomas Livingstone, a British engineer, born in Stirlingshire, Scotland, in 1792, died near Sydney, Australia, Oct. 5, 1855. He joined the British army in the peninsula in 1808, attained the rank of major, and made military maps of the peninsula battle fields. In 1827 he was appointed deputy surveyor general of eastern Australia, and ultimately surveyor general, which office he held till his death. He conducted four expeditions into the interior of
MITCHELL'S PEAK

MITFORD

Australia; the first, in 1831–2, resulted in the discovery of the Peel and Nammy rivers; and during the second and third, in 1835–6, the Darling and Glenelg rivers were explored, and Australia Felix discovered. The fourth (1845–6) was undertaken to trace out a route from Sydney to the gulf of Carpentaria; the loss of cattle and horses prevented the completion of the expedition, but it led to the discovery of the Victoria river. During a visit to England Major Mitchell published "Three Expeditions into the Interior of Eastern Australia, with Descriptions of the recently explored Region of Australia Felix," &c. (2 vols. 8vo, London, 1888); and his "Journal of an Expedition into the Interior of Tropical Australia" appeared in 1848. In 1853 he published a lecture on the boomerang propeller, which he had invented for steam vessels. He was knighted in 1853, and made a colonel in 1854.

MITCHELL'S PEAK. See BLACK MOUNTAINS.

MITCHILL, Samuel Latham, an American physician, born in North Hempstead, Long Island, Aug. 20, 1764, died in New York, Sept. 7, 1831. He graduated as M. D. at the university of Edinburgh in 1786, returned to America in the following year, and studied law. In 1799 he was appointed professor of chemistry, natural history, and philosophy in Columbia college, where his dissertation from some of Lavoisier's principles involved him in a controversy with Dr. Priestley, which led to a lasting friendship between the two disputants. In 1796 he made a geological and mineralogical tour along the Hudson. In conjunction with Dr. Edward Miller and Elihu H. Smith he founded the quarterly "Medical Repository," of which he continued to be editor for 16 years. It was the first scientific periodical published in the United States. Twice he was a member of the legislature, and in 1801 he became a representative in congress, and in 1804 United States senator. At the expiration of his term of office he was again elected to the house of representatives. In 1808 he became professor of natural history in the college of physicians and surgeons, and in 1820 of botany and materia medica. In 1826 the institution gave place to the Rutgers medical school, of which Dr. Mitchell became vice president. The poems of "Croaker and co." contain records of some of Dr. Mitchell's eccentricities. He proposed to change the name of this country to Fredonia, and wrote in 1804 "An Address to the Fredes, or People of the United States." He was the author of "Observations on the Absorbent Tubes of Animal Bodies" (12mo, New York, 1787); "Nomenclature of the New Chemistry" (1794); "Life, Exploits, and Precepts of Tammany, the famous Indian Chief," a half historical, half fanciful address before the Tammany society of New York (1795); and "Synopsis of Chemical Nomenclature and Arrangement" (1801).—See "Reminiscences of Samuel Latham Mitchell, M. D., LL. D.," by John W. Francis, M. D. (New York, 1859).

MITE, a name applied to many very small articulated animals, of the arachnoid order and suborder acarina, including the ticks, itch insects, and other parasites, and the minute acari. The abdomen is unarticulated, and fused with the cephalothorax; the external envelope is of chitine, solid and indestructible; four pairs of feet on the cephalothorax, armed with nails, and in some provided with long pedunculated disks by which the animal is attached; some, when young, have six feet; eyes usually absent; mandibles wanting, the antennæ being changed into prehensile and masticatory organs, moving vertically, piercing or cutting as may be necessary, and sometimes enclosed in a sheath in the form of a sucker. The stomach has several cecal appendages, and the short and straight intestine opens in the midst of the abdomen; salivary glands well developed; no apparent heart nor blood vessels, the colorless nutritive fluid filling all the interstices of the body, and being irregularly circulated by the muscular movements and the contractions of the intestinal canal; respiration aerial, performed chiefly by the skin, and in some by tracheæ. The sexes are separate; many have an ovipositor, by which they insert their eggs under the epidermis of plants and animals, in the latter case often causing great irritation; some surround their eggs by a tough substance which glues them to various objects. Their extreme minuteness in some cases may be judged of by the fact that they infest flies and very small insects; they are exceedingly prolific. Some live under stones, others on plants, on animals, or among decaying organic substances, and a few are aquatic; the parasitic ones, sucking the blood of animals and man, are sometimes very annoying. The itch insect has been described under Ircn, and the ticks and other mites under Erizo. Among the mites, the acarus domesticus is found especially in old cheese (the powder of which, so agreeable to epicures, is made up of these little animals with their eggs and excrement, in flour, sugar, and on figs and sugared fruits; the A. destructor feeds on the specimens of the entomologist and zoologist; the garden mites (trombidiiide) live on fruits, flowers, and leaves; the spider mites (gammaside) include the minute red spider of hothouses; and the wood mites (oribatide) creep among stones and moss.

MITFORD, Mary Russell, an English authoress, born at Aireford, Hampshire, Dec. 16, 1786, died near Reading, Jan. 10, 1856. She was the daughter of a physician whose pecuniary speculations early involved his family in ruin. Her education was chiefly acquired at a school in Chelsea. At 20 years of age she published three volumes of poems, some of them long narratives in the style of Scott; and about 1812 she adopted literature as a profession,
and for several years contributed tales and sketches to the magazines and annuals. Irving's "Sketch Book" first suggested to her the idea of writing sketches of the daily life of the rural population, and her most popular work is "Our Village," the scene of which is the little hamlet of Three Mile Cross, near Reading. These sketches, after being declined by the "New Monthly Magazine," edited by Thomas Campbell, were first published in the "Lady's Magazine" about 1820, and were extended to five volumes or series (1824–32). Among her other prose works are "Country Stories" and several of the "Edinburgh Tales" published by Mrs. Johnstone in 1845. She also edited "three volumes of "Stories of American Life by American Authors," and four of the annual volumes of Finden's "Tableaux." Her dramas, "Julian" (1823), "Foscari"(1826), "Rienzi" (1828), and "Charles the First," were performed with success, "Rienzi" being the most popular. Her "Charles the First" was prohibited by George Colman, the licenser, for its supposed revolutionary sentiments, but was finally produced at the Colburt theatre in London. She also wrote several dramas which were never acted, and an opera, "Sadak and Kalsander," the music of which was written by Packer. In 1838 she received a pension. In 1832 appeared her "Reollections of a Literary Life" (3 vols. 12mo), and in 1854 "Atherton and other Tales," and a collected edition of her dramatic works in two volumes. For upward of 40 years she lived in a little cottage in Berkshire. About three years before her death she was injured by the overturning of her chaise, and the remainder of her life was passed in much physical suffering. —See "Life of Mary Russell Mitford," edited by the Rev. A. G. L'Estrange (3 vols., London, 1870).

MITFORD, William, an English historian, born in London, Feb. 10, 1744, died in Hampshire, Feb. 8, 1827. He entered Queen's college, Oxford, left it without a degree, studied law at the Middle Temple, but soon retired to his ancestral estate in Hampshire, married, and devoted himself to literature. By the advice of Gibbon, he wrote a history of Greece (5 vols., 1784–1818), bringing the narrative down to the death of Alexander the Great. He was prevented by age and failing eyesight from carrying on the work, as he had intended, to the period of the Roman conquest. An edition of it by his brother Lord Redesdale, with an introduction, appeared in 1829 (8 vols. 8vo). He also published a treatise on the religions of ancient Greece and Rome, as a supplement to his history; "An Inquiry into the Principles of Harmony in Languages and of the Mechanism of Verse, Modern and Ancient" (1774); and "A Treatise on the Military Force, and particularly the Militia, of this Kingdom." He was a member of parliament for 21 years, held several public offices, and was professor of ancient history in the royal academy.
spatch him with his sword. It is said that to avoid being poisoned, which he was apprehensive of, he had accustomed himself to the use of antidotes to such a degree that the most baneful drugs had little effect on him. His son sent his body to Amias to a peace offering to Pompey; but the Roman general caused it to be interred with regal honors in the sepulchre of the Pontic kings at Sinope. Mithridates had a powerful memory, was well acquainted with Greek literature, and understood more than 20 languages which were spoken in his dominions.

MITRAILLEUSE. See Artillery, vol. 1, p. 792.

MITRE (Gr. μιτρα), an ornament worn upon the head by certain ecclesiastics of the Roman Catholic and Greek churches, consisting of a stiff cap rising in two points, one before and the other behind, and having two ribbon-like pendants which fall on the shoulders. In the strict generic sense, the ancient mitra was a scarf which was sometimes bound around the thyrsus of Bacchus and his votaries in the celebration of his rites. In a secondary sense, it was a scarf worn like a turban by the Persians and Arabians, and by the women of Greece.

The mitra worn by the Phrygians and Amazons was a pointed cloth cap tied by strings or lappets under the chin. Bacchus was often represented with a mitra, from which the Greeks gave him the name μιτροφόρος. The Persian deity Mithra and the Egyptian god Osiris appear with a similar head covering, and it has also been traced in India. The Jewish high priests wore the mitnepheth, which was copied from the mitre made for Aaron (Exod. xxviii.), on the front of which, over a blue lace, was a plate of pure gold, having engraved on it, "like the engravings of a signet, Holiness to the Lord." When the mitre was first adopted by Christian ecclesiastics is uncertain, but it is supposed that its first form was a circlet of silver gilt or of gold, set sometimes with precious stones, and called στέφανος or corona, and κόσμημα or diadema. In the 6th century John of Cappadocia, bishop of Constantinople, added to this band embroidered fringes and sacred images. In the western churches a white linen kerchief was worn, tied behind by a bandage, the ends of which fell on the shoulders. In the beginning of the 8th century it was customary to wear both the kerchief and the corona. In the latter part of the 10th century the mitre was a close-fitting cap with a round top; in the 11th the horns began to show themselves in two short points on the sides above each ear; and in the 12th century these had grown into low round protuberances. Toward the beginning of the 13th century the mitre took a different shape, the two horns being more elevated and worn in front and behind, as at present. At the period of the renaissance it assumed its present bulging shape and undue height. Three kinds of mitres are now used in the Roman church: the precious mitre, often made of gold or silver and adorned with gems; the gold-embroidered mitre, made of cloth of gold or white silk embroidered with gold; and the plain mitre, of white damask or linen, with red edging or fringe on the lappets. The use of the mitre is not restricted to bishops; cardinals, abbots of great houses by special papal privilege, and canons of highly favored cathedrals or royal collegiate churches, are allowed to wear it. In the English church the mitre has not been worn since the coronation of Queen Elizabeth.

MITSCHERLICH, Elibard, a German chemist, born at Neuenahr, near Jever, grand duchy of Oldenburg, Jan. 7, 1794, died in Berlin, Aug. 28, 1863. He was the son of a clergyman, and studied at the gymnasium of Jever, where Schlosser instructed him in oriental history and philology. He pursued his studies especially in this department at Paris, Heidelberg, and Göttingen, where he published Mitochondia Historia Thaeriderarum (1815); and in 1818 he went to Berlin to study chemistry. He discovered the law of isomorphism, for which he received the medal of the royal society of London. At the invitation of Berzelius he accompanied him to Stockholm in 1819, and passed two years in his laboratory. On his return to Berlin, he succeeded Klaproth in the academy of sciences and in the chair of chemistry. His first results in the discovery of isomorphism were presented to the Berlin academy in 1819, and next year they were generally accepted. Its doctrine was developed by him in a long series of observations. In 1823 he completed the theory by the discovery that some substances, as sulphur and carbon, under different circumstances, crystallize in two dissimilar forms. Such bodies are termed dimorphous. The reports of his
investigations and discoveries are chiefly contained in a large number of papers in the journals of the Berlin academy and in the *Annalen* of Poggendorff. He also published *Lehrbuch der Chemie* (Berlin, 1829-40; 5th ed., 1853 et seq.). He perfected the instruments for measuring the angles of crystals, and extended his researches to the influence of heat on crystallization. Many instruments of his invention have been adopted in Germany and other countries. He was one of the few foreign associates of the French institute. His posthumous work *Ueber die vulkanischen Ersecheinungen in der Eifel und über die Metamorphie der Gesteine durch erhöhte Temperatur*, edited by J. Roth, was published in Berlin in 1865. See Rose's *Gedächtnissrede* (Berlin, 1864).—His brother, KARL GUSTAV (born Nov. 9, 1805, died March 16, 1871), was professor of medicine at the university of Berlin. His principal work is *Lehrbuch der Arzneimittellehre* (2 vols., Berlin, 1847-51).

MITTERMAIER, Karl Joseph Anton, a German jurist, born in Munich, Aug. 5, 1787, died in Heidelberg, Aug. 28, 1867. He studied at Landshut and Heidelberg, was for many years professor in the former university, and in 1819 removed to Bonn. In 1821 he accepted the chair of jurisprudence at Heidelberg, which he retained until his death. He defended trial by jury in Germany, and sustained (theoretically) the codification of the French civil law against the attacks of Hugo, Savigny, and others. His *Lehrbuch des deutschen Privatrechts* (Landshut, 1821) was subsequently merged in his *Grundzüge des gemeinen deutschen Privatrechts, mit Einschluss des Handel-, Wechsel- und Söderrechts* (2 vols., Ratisbon, 1837-78). His first work on criminal law, *Handbuch des privatrechten Prozesses* (2 vols., Heidelberg, 1810-12), was republished, enlarged and modified, under the title of *Das deutsche Strafverfahren in der Fortbildung durch Gerichtsgebrauch und Particulargesetgebung* (2 vols., 1832), and has passed through many editions. The principles relating to the examination of witnesses in criminal law are expounded in his *Theorie des Beweises im privatrechten Prozesse* (2 vols., Darmstadt, 1821), in *Die Lehre vom Beweise im deutschen Strafprozesse* (1834; French translation, 1848; Spanish, 1851), and in *Anleitung zur Vertheidigungskunst im Criminalprozesse* (translated into Italian by Garba, 1859). His manual of criminal law (*Lehrbuch des Criminalprozesses*) has passed through numerous editions. A comprehensive exposition of the principles upon which civil trials should be conducted is contained in his *Der gemeinsame deutsche bürgerliche Process* (1820-26). His *Die Mündlichkeit des Anklagespruchs, die Öffentlichkeit und das Geschevengericht* (Stuttgart, 1845), brings the investigation and the enactments relating to trial by jury down to the period of its publication; and his *Das englische, schottische und nordamerikanische Strafverfahren* (Erlangen, 1851), treats of the administration of justice in England, Scotland, and the United States. His subsequent works include *Die Gefängnisverbesserung* (1858); *Der gegenwärtige Zustand der Gefängnisfrage* (1860); *Die Todesstrafe, &c.* (Heidelberg, 1869); and *Erfahrungen über die Wirk- samkeit der Schurverrichte in Europa und Amerika* (1866). Mittermaier was a member of the Baden legislature for nearly 20 years previous to 1841, when his grief at the death of his son caused him to withdraw; during that time he had been three times president of the legislature; and having resumed his seat in 1846, he was again president during the session of 1847-78. In 1848 he was first called upon to preside over the provisional parliament at Frankfort; and he was a member of the German parliament, where he advocated confederation, but opposed all extreme measures. He frequently visited Italy, and embodied the result of his observations in *Italienische Notizen* (Heidelberg, 1841).

MITTIMES, in law, the pretense which is addressed by competent judicial authority to a sheriff, constable, or other officer, and to a jailer or keeper of a prison, commanding the one to take and deliver, and the other to receive into custody, a person charged with the offence therein described, and safely keep him as therein commanded. The command to keep varies with the nature of the case. A mittimus may be issued by an examining magistrate who, having inquired into a charge of crime, has decided that there is probable cause to believe it true; and then, if the offence is bailable and sureties be not offered, a mittimus will issue commanding the jailer safely to keep the person charged for want of sureties, or until he be discharged by due course of law. But a mittimus may also issue for confinement in punishment of crime, and then the command will be safely to keep the prisoner for a time specified. A mittimus should be under the hand and seal of the magistrate; it should plainly specify the offence charged, and contain sufficient to show on its face that the magistrate had authority to act in the case; but it need not recite the evidence.

MITTOO, a country of central Africa, between the Roah and Rohl rivers, and between lat. 5° and 6° N., bounded N. by the territory of the Dinka and S. by that of the Nyam-nyam. The most northerly group of tribes is that of the Mittoo proper; the other tribes are the Madi, the Madi-Kaya, Abbakah, and Loobah. Tattooing is practised only among the men. Both sexes wear iron and copper ornaments and trinkets of every sort; they have a great partiality for chains, for fastening objects to their bodies, and their inventive skill in armlets and rings for the ankles is remarkable. Thick chains of iron on the neck are signs of fashion and wealth, and the ambitious often wear four at a time. The country is fertile, especially between lat. 5° and 30° N., on the upper Roah and Wolko,
and various cereals, tuberous plants, and oily
and leguminous fruits are produced with little
labor. They eat the flesh of dogs, and possess
goats and poultry, but have no cattle, and are
hence contemptuously called Dyoor or savages.
They use the bow and arrow and spears, but
not shields. They have been lately subjected to
the authorities at Khartonoo, and attempts
have been made to employ them as "bearsers,"
or attendants on military and trading expedi-
tions, but with little success, owing to their
general debility.—See Schweinfurth's "Heart
of Africa" (2 vols., 1874).

MITYLENE. See MYTILENE.

MIXTECS, a nation of Indians in Mexico,
who emigrated at an early period from the
north, under chiefs who were said to have sprung from two trees. They displaced the
Chuchones or Chochos, and occupied most of
the present states of Oajaca, Guerrero, and
Puebla. They were industrious and progressive,
and were not governed by one ruler,
but by independent chiefs. Some of the bands
were reduced by the Aztecs, and paid them
tribute in feathers, chalchihuitl, cotton robes,
maize, and firewood; but those of Oajaca
remained independent. Remains of their cities,
temples, and fortresses show that they pos-
sessed considerable civilization. They had ac-
cred caves in their mountains, and believed in
a heaven called Sosola. They have held their
ground in part of the territory, but in Puebla
have been displaced by Mexicans, and some
bands were forced down into Guatemala. Their
language is allied to the Zapoteca, but is more
melodious and less difficult. It has several
dialects, 11 according to recent authorities, of
which the Tepuzculano is the principal. The
language has no b, f, p, or r. It has no proper
plural, esdlte, equivalent to many, being added
to the singular; it abounds in personal pro-
nouns, and the negative particle varies ac-
cording to the tense of the verb. A full diction-
ary was compiled by F. Diego Rio; an Arte
or grammar was published at Mexico in 1500
by Fray Antonio de los Reyes; and several reli-
gious treatises were printed in Mixtecana in
the 16th and 17th centuries. At present they are
peaceable and intelligent Mexican citizens.
Protected by mountain fastnesses, they take
little part in revolutions occurring beyond their
limits. Their chief cities are Tepuscoluta, Yan-
bhuatan, Taxiaco, and Tepascaluta.

MNEMONICS (Gr. mnemos, memory), the art of
rendering artificial aid to the memory by asso-
ciating in the mind things difficult to remem-
ber with those which are easy of recollection,
so that the former may be retained and brought
to mind by association with the latter. The
art is supposed by some writers to have origi-
nated with the Egyptians, but the first person
who reduced it to a system was, according to
Cicero, the poet Simonides of Cos (about 500
B. C.). Having been called from a banquet
just before the roof of the house fell and
crushed all the rest of the company, he found
on returning that the bodies were so mutilated
that no individual could be recognized; but by
remembering the places which they had sev-
erally occupied at table he was able to distin-
guish them. He was thus led to remark that
the order of places may by association suggest
the order of things. The principles of the art
were introduced at Rome and Germany by
Metrodorus, and Cicero and Quintillian both ad-
vocated the plan of associating thoughts and
words with particular places, images, or signs
which might be recalled at pleasure. One of
the earliest modern works on the subject is the
Fontix (1491) of Petrus Ravenus, professor of
canon law in Padua. One of his artifices was
to make beautiful maidens the letters of an
alphabet. John Romberch de Kryptse, in his
Congestorium Artificiosum Memorie (1539), re-
commended the division of the walls of a series
of rooms into separate spaces, each of which
was to be marked with numerical, literal, and
symbolical alphabets. The distinct rooms were
to be devoted, like the alcoves of a library, to
distinct classes of subjects; and the nomen-
cature having once been mastered, the sugges-
tions of local relation would enable a man to
repeat hundreds of words or ideas that had no
real connection with one another. The same
method is developed further in the "Castel of
Memorie" of Guillelm Grataroll of Bergramo,
published in English in 1562. The Ars Memori-
aria of Marsafortius (1602) grouped all neces-
Sary reminiscences around 44 images contained
in the palms of the hands. Giambattista della
Porta, in his Ars Reminiscenti (1602), seems
to have first employed the mode of writing
now common in rubbuses. About 1600 Lam-
bert Schenkel astonished all classes in France,
Germany, and the Netherlands by his mnemonic
performances. His system, which was similar
to that of Simonides, was obscurely explained
in his Gazophylacium Artis Memoriae (1610).
He was succeeded at the university of Paris, where
he taught for many years, by his pupil Martin
Sommers, who became equally celebrated. More
elaborate than any preceding scheme was the
repository for ideas suggested by John Wallis
in his Mnemonica (1615). This repository
was to be a series of imaginary theatre-shaped
edifices with their interior walls variously di-
vided and colored. Every person was to have
his repository constantly present before his
mind, within which all his ideas were to be
arranged according to their qualities, quanti-
ties, positions, and colors. The plan only be-
came more complicated as improved by Henry
Herdsen (1651). The Memoria Technica of
Richard Grey (1730; new ed., 1851) contains
a system which many have found useful in
remembering dates and numbers. Letters are
substituted for figures and combined into
words; certain consonants are selected for
this purpose, the vowels serving only to con-
nect them. Grey's letters, which were adopt-
ed without reference to any similarity to the
figures they stand for, are as follows:
Words formed from these letters by combination with any of the vowels are more easily numbered than the figures they represent. The most complicated system of mnemonics is that of Fainaigne, who began to lecture in Paris in 1807 and in England in 1811. He divides the walls, ceiling, and floor of a room into 50 imaginary equal compartments. To each compartment is assigned a particular hieroglyphic, with which it is indissolubly associated. These elements have been thoroughly mastered, some association, no matter how ridiculous, is formed between the object to be remembered and one of the hieroglyphs. The substitution of letters for figures also belongs to his system. His table is as follows:

1 2 3 4 5 6 7 8 9 0
t n m r l d c q g b v w p f k z

He selected these letters on account of some similarity to or association with the figure represented; as, for example, t resembles the figure 1, m with two strokes suggests 2, m with three strokes suggests 3, r occurs in the word denoting four in the European languages, &c. Fainaigne published a work in English illustrative of his system, entitled “The New Art of Memory” (London, 1812). His system was improved by Aimé Paris (“Principes et applications diverses de la mnémotechnie,” 7th ed., Paris, 1833), who applied his method to chronology, geography, jurisprudence, mathematical formulas, and the nomenclature of all the sciences. Further modifications were made by F. Fauvel-Gouraud, who taught in the United States and published “Phreno-Mnemotechnic Dictionary” (part i., New York, 1844), and “Phreno-Mnemotechny, or the Art of Memory” (1845). Among other late writers on mnemonics are Gen. Benn, Exposé général de la méthode mnémonique polonaise, &c. (Paris and Leipzig, 1859); an enlargement of Jazvinski’s system: Hermann Kohth, System der Mnemonik (Cassel, 1853); and Karl Otto-Reventlow, Mnemotechnischer Kommentar zur allgemeinen Weltgeschichte (Stuttgart, 1861).

MNEMOSYNE (Gr.), in classical mythology, the goddess of memory, one of the Titanides, daughter of Uranus, who became by Jupiter the mother of the Muses.

MOA. See DINORIS.

MOAB, the ancient name of a region on the E. shore of the Dead sea and the E. bank of the Jordan, about 50 m. long by 20 broad. It is designated in Scripture as the land of Moab. The plains are well watered and very productive. The uplands consist of a rolling plateau about 3,200 ft. above the sea, which descends at angles of 45° and 50° into the Dead sea. The great chasm of Wady Mobaj, the Arnon of Scripture, divides them into two districts, of which the northern is called by the modern Arabs El-Belka, and extends as far N. as the mountain of Gilead; while the southern is known as El-Karak, and reaches southward to the wady of that name. The village of Kerak is supposed to stand upon the site of one of the ancient capitals of Moab, called in the Old Testament Kir-Haraseth (2 Kings iii. 25), Kir-Heareseth (Isa. xvi. 7), Kir-Haresh (Isa. xvi. 11), Kir-Heres (Jer. xlviii. 31, 36), or Kir-Moab, an earlier one having been Ar, or Rabbath-Moab. It is built on the top of a steep hill surrounded by a deep and narrow valley. The land is now inhabited by a few scattered Arab tribes, but is covered with ruined villages and towns. According to the Biblical account, Moab was a child of Lot, and his descendants conquered before the time of the exodus a gigantic tribe called Emmim, and took possession of their land; but they lost a portion of it to the Amorites, from whom it was taken by Moses. Balak, king of Moab, formed an alliance with the Midianites to resist the invading Hebrews, and sought to persuade Balaam the seer to curse them; but Balaam by divine direction blessed them. Subsequently Balaam seduced the Hebrews to join in the worship of Baal-peor. The Midianites were thereupon attacked by command of the Lord, and suffered great losses, but the Moabites were spared. Moses died and was buried in the land of Moab, in a ravine facing Beth-peor, the house of Baal-peor. During the time of the judges Eglon, king of Moab, united with the Ammonites and Amalekites and subjugated the Israelites; but after ruling and receiving tribute in Jericho for 18 years, he was killed by Ehud the Benjamite, and the Moabites were driven back to their own territory. Moab was conquered by Saul, and David made it a tributary state. After the division of the Hebrew state, the Moabites revolted against Ahab, king of Israel, whose son Jehoram tried in vain to reconquer their territory. They subsequently made various incursions into the Hebrew possessions, and appear in later times to have reoccupied the land between the Jabbok and Arnon, probably after the death of the ten tribes, and they also assisted the Babylonians in their invasion of Palestine. But they, too, were subdued by the conquerors. Their name, like those of Ammon and Edom, was finally lost under that of the Arabs. Their licentious and bloody idolatry of Baal-peor and Chemosh made them an object of national detestation to the Hebrews, no less than their frequent hostilities, and they are often contemptuously spoken of in the prophets.—The discovery in 1868, at Dhiban in Moab, of a monument of black basaltic granite, with an inscription of 34 lines in Hebrew-Phoenician characters, attracted re- newed attention to this country. The only European who saw the Moabite stone in a complete state was the Rev. Mr. Klein, of the Jerusalem mission society. The negotiations set on foot to obtain possession of it unfortunately resulted in quarrels among the Arab tribes, and led them to believe that the Turks would
MOAWIYAH

The founder of the dynasty of the Ommiyade caliphs, born in Mecca about 610, died in Damascus in the spring of 680. He was the son of Abu Sulian, one of the chiefs at Mecca, and the great-grandson of Om\n\niya, a cousin of the grandfather of Mohammed. In 641 Omar appointed him governor of Syria; and although he permitted the island of Cyprus, which fell into Saracen power about 648, to be recaptured by its people in 651, he subjugated and retained the island of Rhodes.

On the assassination of the caliph Othman in 653, he refused to recognize Ali, his legiti\n\nmate successor, but proclaimed himself ca\n\nlip. After a long struggle, in which he often displayed tyranny and revolting cruelty, he succeeded in subjugating the whole Saracen empire, and placing its provinces under the control of governors friendly to him. His armies made large additions to his territory, conquering Bokhara and Samarqand on the north, and meeting with no important check until they attacked Constantinople, which was repeatedly besieged until in 678 Moawiyah was compelled to make terms of peace. He made the caliphate hereditary, though the measure excited great opposition, and com\npelled the recognition of Yazid, his son, as his future successor. II. Grandson of the preceed\ning, born in Damascus in 660, died there in 686.

He succeeded Yazid as caliph in the autumn of 683, but abdicated a few months later, declaring that the act of his grandfather in making the caliphate hereditary had been one of usurpation, in the results of which he would not share. He refused even to appoint a suc\n\ncessor, but retired to a life of complete pri\n\nvacy. According to some historians, he died of the plague; according to others, he was poi\n\nsoned. (See OMMIYADES.)

MOBERLY, George, an English bishop, born in 1808. He graduated at Oxford in 1825, and became successively fellow and tutor of Balliol college, public examiner, and select preacher before the university. In 1835 he was appointed head master of Winchester school. In 1868 he was the Bampton lecturer, and in 1869 he was made bishop of Salisbury. His nu\n\merous publications include "Introduction to Logic." (1838); "Sermons preached at Win\n\nchester College" (2 vols., 1844-48); "Sayings of the Great Forty Days, with an Examination of Mr. Newman's Theory of Development" (1846; 4th ed., 1871); "Studies and Discipline of Public Schools" (1861); "The Administra\n\ntion of the Holy Spirit in the Body of Christ" (Bampton lectures, 1868); and "Brightstone Sermons" (1869).

MOBILE, the name of a river and bay in the southern part of Alabama, derived from that of a tribe of Indians (the Moovilians or Mo\n\nbulians) who inhabited the adjacent country at the time of its first settlement by Europeans. The river Mobile is formed by the confluence of the Alabama and Tombigbee. A few miles below this point it divides into two branches, the eastern one of which takes the name of Tensas, the western retaining that of Mobile. Before reuniting, both these streams separate into several other subdivisions, all of which meet in one common embouchure at the head of Mobile bay. The length of the Mobile river is about 90 m., and its general direction
is south. In the lower part of its course the banks are marshy and alluvial.—The bay of Mobile is about 30 m. in length from N. to S., with a general width of 10 or 12 m., except where it expands on the southeast into the subsidiary bay of Bon Secours, which extends some 8 or 10 m. further to the eastward. The entrance from the gulf of Mexico, between Mobile point on the east and Dauphin island on the west, is about 3 m. wide, and is commanded by Fort Morgan on Mobile point, and Fort Gaines on Dauphin island. The bay has another outlet on the southwest through Grant’s pass, N. of Dauphin island, which communicates with Mississippi sound. Through this channel steamers and other vessels of light draught generally pass when plying between Mobile and New Orleans. The bar in front of the main entrance of the bay admits of the passage of vessels drawing 21 or 22 ft. The ordinary anchorage for ships is 4 or 5 m. within the entrance of the bay. The whole of the upper portion of the bay is shallow, and is supposed to be gradually filling up with sedimentary deposits from the rivers that flow into it. There is a lighthouse on Mobile point; another on Sand island, 3 m. S., immediately in front of the entrance; and one at the head of the bay, a little below the city of Mobile.

MOBILE, a S.W. county of Alabama, bounded E. by Mobile river and bay, S. by the gulf of Mexico, and W. by Mississippi; area, nearly 1,400 sq. m.;-pop. in 1870, 49,311, of whom 21,107 were colored. The surface is generally uneven, except in that portion bordering on the bay and gulf, and the soil is sandy and poor, mainly covered with forests of pine. It has many streams of pure water, and, except on the low borders of the river, is very healthful. The county is traversed by the Mobile and Ohio, the New Orleans, Mobile, and Texas, and other railroads terminating at Mobile. A few miles S. of the main line, in the gulf of Mexico, immediately W. of the entrance to Mobile bay, forming a part of the county, is Dauphin island, the seat of a French settlement established by Bienville in 1702. It was originally called Massacre island, from the number of human bones found upon it. For several years it was at intervals the seat of government of the colony of Louisiana. The chief productions in 1870 were 61,550 bushels of Indian corn, 10,394 of Irish and 67,116 of sweet potatoes, 50,100 lbs. of rice, 7,592 of wool, 1,450 of honey, and 317 bales of cotton. There were on farms 451 horses, 492 mules and asses, 3,214 milch cows, 518 working oxen, 4,377 other cattle, 3,013 sheep, and 5,567 swine. There were 5 flour mills, 12 saw mills, 11 manufactories of tin, copper, &c., 14 of cigars, 2 of engines and boilers, and 5 of tar and turpentine. Capital, Mobile.

MOBILE, a port of entry and the capital of Mobile co., Alabama, the largest city and only seaport of the state, on the W. side of Mobile river, immediately above its entrance into the bay of the same name, 30 m. from the gulf of Mexico, in lat. 30° 42' N., lon. 88° W., 180 m. S. W. of Montgomery, and 140 m. by rail E. by N. of New Orleans; pop. in 1820, 2,073; in 1830, 8,194; in 1840, 12,972; in 1850, 20,215; in 1860, 29,268; in 1870, 32,024; of whom 15,919 were colored and 4,239 foreigners. The number of families was 6,301; of dwellings, 5,758. The corporate limits extend 6 m. N. and S., and 2 or 3 m. W. from the river. The thickly inhabited part of the city extends for about a mile along the river, and nearly the same distance back to the westward. Its site is a sandy plain, rising as it recedes from the water. The streets are generally regular, well paved, and shaded. There are several fine public buildings, among which is a handsome market house with rooms for the municipal offices in the upper story. The custom house has also accommodations for the post office and United States courts. Among the other noticeable buildings are the theatre, Odd Fellows’ and temperance halls, guard house and tower, medical college, and the Bar ton academy. Mobile is lighted with gas, and supplied with water of unusual purity and excellence, which is brought a little more than 5 m., from the foot of Spring hill. Six lines of street railroad traverse the city. The climate is generally healthful, except for occasional visitations of yellow fever. High and healthful hills within a few miles N. and S. W. afford permanent or summer residences. Four lines of railroad furnish communication with various points in the south, viz.: the Mobile and Ohio; Mobile and Montgomery; New Orleans, Mobile, and Texas; and Alabama Grand Trunk. The trade of Mobile is much hindered by the shallowness of its harbor. Vessels drawing more than 8 or 10 ft. are obliged to anchor in the bay, 23 m. or more from the city. In 1873 congress appropriated $100,000 for the completion of improvements in the harbor, with which it is hoped that large vessels of 13 ft. draught will be enabled to reach the wharves. The chief business is the receipt and shipment of cotton. The following table exhibits the number of bales received and shipped for six years:

The trade in naval stores and lumber produced in the vicinity is increasing. In 1873 the shipments consisted of 15,000 to 20,000 barrels of spirits of turpentine, 75,000 to 100,000 of rosin, and 1,000 of tar, together valued at $750,000, and 2,627,640 ft. of lumber. The importation of coffee is also increasing, and in 1872–3 amounted to 58,966 bags. The
Of the exports in 1874, $2,842,820 consisted of cotton. The entrance from foreign ports during the year ending June 30, 1874, numbered 58, with an aggregate tonnage of 35,667; clearances to foreign ports 41, tonnage 23,509. The coastwise entrances were 185, tonnage 48,373; coastwise clearances, 123, tonnage 45,115. In 1873 80 sailing vessels of 7,556 tons, 80 steamers of 7,316 tons, and 22 barges of 1,475 tons, belonged to the port. Steamers run regularly to Montgomery and other points on the Alabama, Tombigbee, and Black Warrior rivers. The principal manufactory are two of saah, doors, and blinds, one of paper, several of carriages and cabinet ware, two cooperages, a brewery, three saw mills, and four foundries and machine shops. There are two national banks, with a joint capital of $800,000; two state banks, with $1,000,000 capital; two savings banks, and nine insurance companies.—Mobile is divided into eight wards, and is governed by a mayor, with a board of councilmen of one member and a board of aldermen of three members from each ward. It has a municipal court and an efficient fire department and police force. The United States courts for the southern district of Alabama are held here. The principal charitable institutions are four orphan asylums, the city hospital, the United States marine hospital, and the Providence infirmary. The medical college of Alabama was established here in 1859, and in 1873-4 had 9 professors and 85 students. The number of public schools in the entire county in 1873-4 was 71 (43 white and 29 colored), with an attendance of about 4,500. The boys and girls' high schools and a number of the lower grades are held in the Barton academy in the city. There are seven Roman Catholic schools and academies, a Hebrew school, and a number of private schools and academies. Two daily newspapers are published. There are 30 churches, viz.: 5 Baptist (2 colored), 4 Episcopal, 1 German Lutheran, 1 Jewish, 10 Methodist (6 colored), 3 Presbyterian, and 6 Roman Catholic. In the immediate vicinity of Mobile are the college of St. Joseph at Spring Hill, under direction of the Jesuits, and the academy of the Visitaton, Summerville, conducted by the sisters of the Visitaton,—Mobile was the original seat of French colonization in the southwest, and for many years the capital of the colony of Louisiana. In 1702 Le Moyne de Bienville transferred the principal seat of the colony from Biloxi to a point on the river Mobile supposed to be about 20 m. above the present city, where he established a fort which he called St. Louis de la Mobile. At the same time he built a fort and warehouse on Isle Dauphine, at the entrance of Mobile bay. Many of the first settlers were Canadians. In 1705 an epidemic, supposed to be the first recorded visitation of yellow fever, carried off 35 persons. The year 1706 was noted for the "petticat insurrection," a threatened rebellion of the women, in consequence of dissatisfaction with the diet of Indian corn. The colony frequently suffered from famine, as well as from the attacks of Indians, although relieved by occasional supplies from the mother country. In 1711 the settlement was nearly destroyed by a hurricane and flood, in consequence of which it was removed to its present situation. In 1723 the seat of the colonial government was transferred to New Orleans. In 1763, by the treaty of Paris, Mobile, with all that portion of Louisiana lying E. of the Mississippi and N. of Bayou Iberville, Lakes Maurepas and Pontchartrain, passed into the possession of Great Britain. In 1780 the fort, the name of which had been changed to Fort Condé, and subsequently by the British to Fort Charlotte, was captured by the Spanish general Don Galvez, and in 1783 its occupancy was confirmed to Spain by the cession to that power of all the British possessions on the gulf of Mexico. On April 13, 1813, the Spanish-commandant, Cayetano Perez, surrendered the fort and town to Gen. Wilkinson. At that period the population, which in 1785 had amounted to 746, was estimated at only 500 (exclusive of the garrison), half of whom were blacks. In December, 1819, Mobile was incorporated as a city. On Jan. 4, 1861, the state authorities of Alabama took possession of the United States arsenal at Mount Vernon, 35 m. from Mobile, and soon afterward garrisoned Forts Morgan and Gaines at the entrance of the bay, though the state did not secede until the 11th. Mobile was not seriously attacked until the summer of 1864, when the city had been encompassed with three lines of defensive works, while ten batteries commanded the channel below the city, which was also obstructed with rows of piles, and a small confederate fleet, carrying 32 guns and 470 men, was anchored under the guns of Fort Morgan. On Aug. 5 Admiral Farragut, with 18 vessels, carrying 199 guns and 2,700 men, entered the bay under the fire of the two forts, which he returned while passing, but without stopping. He was assisted by 1,500 soldiers, under Gen. Gordon Granger, who were inducted on Dauphine Island, within half a mile of Fort Gaines. Farragut's leading vessel, the Tecumseh, struck a torpedo and instantly sank, carrying down her captain and 112 men. The flag ship Hartford, with the admiral in the rigging, then took the lead, and after an engagement lasting an hour passed the forts and steamed into the bay, followed by
the remainder of the fleet. They at once encountered the confederate fleet, which after a sharp conflict was destroyed or captured; the most formidable vessel, the ram Tennessee, did not surrender until a 15-inch shot had penetrated her armor, her steering apparatus had been disabled, and the commander of the fleet, Admiral Buchanan, seriously wounded. The Union loss in this engagement was 62 killed, 170 wounded, and 113 drowned. The confederate loss in the fleet was 10 killed and 19 wounded; in the two forts, 8 killed and 21 wounded. Fort Gaines, with 800 men, surrendered on the 8th. Fort Morgan was at once besieged; it was bombarded and almost entirely destroyed on the 22d, and surrendered on the morning of the 23d. Late in March, 1863, Spanish Fort and Blakely, fortified places on the eastern shore of the bay and Tensas river, were invested by a force of 45,000 men, under Gen. Granger, Steele, and A. J. Smith. These forts were carried by assault on the 8th and 9th of April, 4,000 prisoners being captured, while heavy losses were sustained by the besiegers. Mobile being thus exposed to attack from the river, it was evacuated by the confederates on the 11th, and occupied by the Union troops next day.

**MOBILE POINT**, the apex of a long, low, narrow, sandy peninsula between the gulf of Mexico on the south and Bon Secours bay and Navy cove on the north. The point is the eastern limit of the entrance into Mobile bay. It is the site of Fort Morgan, built in the place of Fort Bowyer, famous for the repulse of an attack by the British, Sept. 14, 1814. The fort, which was very imperfectly constructed, was commanded by Major Lawrence, with a garrison of only 130, including men and officers, and 20 pieces of artillery. It was attacked by a squadron of two sloops of war and two brigs, assisted by 600 Indians on land, with whom were associated 180 marines from the ships. The attack continued for three hours, when the enemy were repulsed, with the loss of the Hermes, Commodore Percy's flag ship, which ran aground and was burned, and 292 men killed and wounded. Eight of the garrison were killed. After the battle of New Orleans, Fort Bowyer was again invested by the whole British force, and Lawrence surrendered, Feb. 12, 1815. (See Mobile.)

**MÖBIUS. I. August Ferdinand**, a German mathematician, born at Schulpforta, near Naumburg, Nov. 17, 1790, died in Leipsic, Sept. 26, 1868. He graduated at the university of Leipsic in 1815, and was a professor there for 50 years. He remodelled the observatory, and in his *Der barycentrische Calcul, ein neues Hilfsmittel zur analytischen Behandlung der Geometrie* (Leipsic, 1827) established the new principle of the affinities of figures. His *Lehrbuch der Statik* (2 vols., 1837) gives a comprehensive account of the intimate connection between statics and geometry. His most celebrated astronomical works are *Die Elemente der Mechanik des Himmels* (1843), and *Die Haupt-sätze der Astronomie* (4th ed., 1860). II. Theodor, a German philologist, son of the preceding, born in Leipsic, June 22, 1821. He graduated at Leipsic in 1852, and in 1859 became professor of Scandinavian languages and literature there. In 1865 he accepted a similar position at Kiel. He has edited many old Norse works. III. Paul Heinrich August, a German author, brother of the preceding, born in Leipsic, May 31, 1825. He studied theology and philosophy, and became a teacher in Leipsic and a preacher at the church of the university. From 1853 to 1865 he was director of an educational institution for book-sellers, and subsequently of one of the principal schools in Leipsic. His miscellaneous writings include stories, poetry, and a tragedy, and *Kätchismus der deutschen Literaturgeschichte* (Leipsic, 1857; 4th ed., 1871). **MOCANNA**, or Mokanna. See Atta Ben Hakem.

**MOCHA** or Mokha, a seaport of Arabia, formerly the capital of the province of Yemen, on the Red sea, at the head of a little bay near the strait of Bab-el-Mandeb, 130 m. N. W. of Aden; pop.; about 7,000. The roadstead is protected only by two narrow spits of sand, on one of which is a castellated fort and on the other an insignificant battery. Vessels drawing 12 ft. of water can enter it. The houses are generally of coral rock or sun-baked brick whitewashed, but in the suburbs they are circular huts built of date-tree matting, with conical roofs. There are three suburbs, one occupied by Abyssinian mariners and Mohammedan traders, one by Arab laborers, and one by Jews. The chief public edifices are the mosques, one of which is very large. Mocha is celebrated for its coffee, the annual export of which, though much less than in former times, was recently still about 10,000 tons. Other articles of trade are dates, gums, balm, ivory, and senna. The growth of Hodeida and Aden has injured the prosperity of Mocha, and its commerce has decreased greatly in late years.

**MOCHUANA.** See Bechuana.

**MOURNING BIRD**, an American passerine bird, of the subfamily *piperinae*, and genus *mimus* (Boie). The subfamily includes the catbird, brown thrush, and nearly 20 other moickers, arranged by Gray under the single genus *mimus*, but subdivided by Cabanis and others into nearly as many genera as species. The restricted genus *mimus* has the bill shorter than the head, slightly curved from the base, and notched at the tip; the gape furnished with bristles; lower jaw with no longitudinal ridges; wings moderate and rounded, with the first quill very short, the second longer, and from the third to the seventh nearly equal and longest; tail long and graduated; tarsi longer than the middle toe, robust, and covered in front with broad scales; toes long, with sharp curved claws. The size is large, and the general appearance thrush-like. The species of this genus
are found in North and South America, the West Indies, and the Galápagos islands; they are shy, active, and migratory, feeding on insects, berries, and worms; the song is highly pleasing, and the powers of imitation are very great.

MOCKING BIRD

The common mocking bird (M. polyglottus, Boie) is about 9/4 in. long, with an extent of wings of 18¼; the bill and legs are black; the general color above is ash brown, a little the darkest in the centre; the under parts white, with a brownish tinge except on the chin, and a shade of ash across the breast; a pale supercilious stripe; wings and tail nearly black; lesser wing coverts like the back; the middle and greater tipped with white, forming two bands; outer tail feather white, the second mostly so, the third with a white spot on the end, and the rest, except the middle, slightly tipped with white. It is found in the southern United States, from the Atlantic to the high central plains, replaced by the M. montanus (Bonap.) to the westward. The song of the mocking bird, in its mellowness, modulations and gradations, compass, and brilliancy of execution, is unrivalled; it can adapt its tongue to any note; it deceives the sportsman, cheats and terrifies birds, whistles to the dog, and imitates almost every sound, animate or inanimate; it sings charmingly at night, commencing as soon as the moon rises; its finest song is during the breeding season. It delights to build in gardens near houses; the eggs are usually five, light green with brown spots and blotches. They begin to pair toward the end of March, and three broods are generally raised between that and the last of September. They remain in the gulf states all the year; some go to the north in the spring, returning in October; they are most plentiful near the seashore, in sandy districts scantily furnished with trees; in winter they live principally about the farm houses and plantations. Their motions on the ground are light and elegant, accompanied by frequent openings of the wings and tail; the flight is short and jerking. The call note is very mournful, like that of the M. rufus (Boie), the French mocking bird so called. Its courage is sufficient to defend it against most birds of prey. It is easily reared by hand from the nest, and becomes very familiar and affectionate in confinement; its vocal powers, though great in captivity, are very much greater in its native haunts; it is long-lived, and a good singer always commands a high price. The female differs little from the male, but the plumage is somewhat duller. The M. Carolinensis (Gray) has been described under Carnum. Other species are described in South America, and on the Pacific coast of North America, all possessing remarkable powers of song.

MODENA

I. A former duchy of northern Italy, bordering on Mantua, Ferrara, Bologna, Lucca, Genoa, Parma, and the Mediterranean; area, about 2,300 sq. m. It comprised Modena proper, Reggio, Guastalla, Frignana, Garfagnana, Massa-Carrara, and Lunigiana. The last three divisions lie S. of the Apennines, the main ridge of which crosses the southern portion of the territory, sending off extensive spurs. The highest summit is Monte Cimone, 7,000 ft. The territory of Modena extended from the Po to the Mediterranean, the coast being small and destitute of harbors. About one third of it, watered by the Panaro, forms part of the great and fertile plain of Lombardy. The principal river is the Secchia, which after a winding course of 100 m. joins the Po opposite the mouth of the Mineo. The principal productions are wheat, maize, hemp, flax, rice, pulse, olives, wine, and silk. Agriculture is backward, but improving. Few of the farms exceed 60 acres; dairy pasture prevails to some extent in the valley of Garfagnana; a few families own the large flocks of Apennine sheep. The vine is most extensively cultivated near Reggio and the city of Modena. The mountains abound with oak, pine, and chestnut. Iron and other minerals are found, and the marble of Carrara is a lucrative article of export. The territory now forms three provinces of the kingdom of Italy: Modena, Reggio, and Massa e Carrara. Its history is given in connection with that of the city. II. A province of the kingdom of Italy, embracing of the former duchy of Modena the provinces of Modena and Frignana; area, 966 sq. m.; pop. in 1872, 273,251. III. A city (anc. Mutina), capital of the province, beautifully situated in a plain between the Panaro and the Secchia, 29 m. N.W. of Bologna; pop. in 1872, 66,680. It has a citadel, surrounded with ramparts, and is divided into the new and old city, a part of the Æmilian way intersecting it. The Gothic duomo or cathedral contains interesting tombs, one of which, designed by Giulio Romano, is celebrated on account of its square marble tower, one of the highest in Italy. Famous among the numerous churches, on account of their colos-
sal marbles, are those of San Vincenzo, Sant' Agostino, and San Francesco. The former ducal (now royal) palace in the great square is a fine edifice, and contains a large collection of paintings by Guido Reni, the Carracci, Andrea del Sarto, Carlo Dolce, and Guercino, Pomaranzio's "Crucifixion," and other remarkable works. It has a recumbent Cleopatra by Canova, and the ceiling of the gallery is painted in fresco by Fracesconi. The library, brought from Ferrara by Cesare d'Este, and hence known as the biblioteca Estense, has about 100,000 volumes, and is rich in manuscripts, coins, and medals. The other public buildings of Modena are the university, one of the most famous in Italy, the museo Lapidario, the theatre, the post office, and the archiepiscopal palace. There are many educational institutions and an academy of sciences and fine arts. Modena is the seat of an archbishop. The university in 1873 had 42 professors and 315 students.—The ancient Mutina is supposed to have been of Etruscan origin. According to Livy, the territory in which it was situated had been taken from the Bolans, and after the final defeat of the latter it was made a Roman colony (183 B.C.). It was a strong place in the time of Sulla, and subsequently became celebrated by the siege which it sustained and the battles fought between Decimus Brutus and Mark Antony, a campaign known as the bellum Mutinense (43). Afterward it suffered much from the general calamities of the empire, and toward the end of the 4th century, according to St. Ambrose, it was in a deplorable condition. In the middle of the 5th century it endured the still more terrible ravages of Attila. Under the Lombard kings Mutina became the frontier city of their dominions toward the exarchate. At the close of the 6th century it was taken by the Greek emperor Mauricius. Subsequently it was restored to the Lombard kingdom, but according to Muratori nearly the whole city was reduced for several centuries to a morass, chiefly owing to inundations. It was governed by Frankish counts for some time after the 9th century, in the 11th by its bishops, and at its close by the countess Matilda of Tuscany. Subsequently it formed part of the Lombard league; and after suffering from the feuds which distracted for a long period the cities of northern Italy, it passed along with Ferrara into the possession of the Torrelli family, and at the end of the 13th century the house of Este became the rulers of the city and its territory. The titles of duke of Modena and Reggio and count of Rovigo were conferred upon Borso of Este in 1458 by the emperor Frederick III. of Germany, and that of duke of Ferrara by Pope Paul II. in 1471. (See Este.) The duchies of Modena and Reggio remained in the Este family till 1797, when Napoleon took them from Ercole III. (who died in 1803), and annexed them to the Cisalpine republic. His daughter Maria Beatrice married the Austrian archduke Ferdinand, and their son Francis IV., who inherited Massa-Carrara, was reinstated as duke of Modena in 1814, and was succeeded in 1846 by his son Francis V., whose elder sister is the wife of the count de Chambord, and his younger sister of the younger son of Don Carlos, the first Spanish pretender of that name, and mother of the present pretender. (See Carlo.) Even more autocratic than his predecessors, he was obliged to invoke the assistance of Austria at the end of 1847 to maintain his authority, and he fled in March, 1848, while
the Modenese established a provisional government. After the defeat of the Sardinian army by Radetzky he returned to his capital, officially set again on March 14, 1859, returned in May, and feigned to be bent on liberal reforms. But he soon relapsed into absolutism and reinstated the Jesuits (June, 1850). In 1859, after the battle of Magenta, he finally left Modena, though the Franco-Austrian treaty of Villafranca confirmed him in his possessions. His dynasty was deposed by the Modenese national assembly, Aug. 19; and by a decree of March 18, 1860, Modena became part of the department of Emilia, in the dominions of Victor Emanuel.

MODICA, a town of Sicily, in the province and 30 m. S. W. of the city of Syracuse, in a narrow valley surrounded by high rocks; pop. in 1872, 33,169. It has a castle, a technical school, a gymnasium, a beautiful cathedral, and several other notable churches. The inhabitants are mostly engaged in agriculture and in the breeding of horses and mules. A brisk trade is carried on in grain, oil, wine, cheese, and other products. About 4 m. from Modica, in the midst of a stony desert, is the valley of Ipsica, famous for its dwellings excavated in the rocks, supposed to be the work of the original inhabitants of Sicily.

MODLIN. See Novogorod-Orlyusk.

MODOCs, a tribe of American Indians, originally part of the Klamath nation, but in recent times hostile to them. The name Modoc was given to them by the Shastees, and means enemies. Their original territory was a district about 100 by 40 m. on the S. shore of Klamath lake, California. They were dark-colored, with a heavy drowsy face and dull yellowish eye. Their houses were pits roofed with a conical structure of wooden slabs, covered with earth. Both sexes were decently clothed in skins. They contended with the Shastees and the Klamaths, and traded in the slaves they captured in war. They recognized a deity called Komoose. As early as 1847 and 1849 they are charged with having cut off more than 50 whites. The Indians on Clear lake chastised by Capt. Nathaniel Lyon in 1850 were apparently of this tribe. After another massacre of whites in 1852 Ben Wright invited the Modocs to a peaceful feast in 1855, and killed 41 out of 46 who came. This act the Modocs never forgave. A campaign against them in 1856 under Gen. Crosby cut off many, but the war was kept up till 1864, when a treaty was made, by which they ceded their lands and agreed to go on a reservation. This treaty was not ratified by the President's proclamation till Feb. 17, 1870, on the reservation officially set apart till March 14, 1871. Meanwhile the Modocs had been induced to go upon the Klamath reservation, but it was a part of the country where they could not live; their own provisions were destroyed, they were cheated out of government allowances, and the Klamaths harassed them. Some were then moved to Yainax reservation, but Klamaths were put with them, and the trouble continued. Two Modoc bands left the reservation. The turbulent band of Captain Jack (Krentpoos), who had set himself up against Schonchin, the hereditary chief, after suffering greatly in the winter, returned in February, 1868, to their old home on Lost river, while the quiet and inoffensive band settled on Hot creek near the whites. Loud complaints were made against Captain Jack's band, and the commissioner of Indian affairs, on April 11, 1872, ordered Superintendent Odeneal to remove them from Lost river to the reservation. On their refusal to go, troops from Fort Klamath moved on Captain Jack's camp, Nov. 29, 1872, and some Oregon citizens on another camp on the opposite side of the river. Fighting ensued at both camps. The whites withdrew with loss, and the Modocs, retreating united, massacred some peaceful settlers on the way, and reached the Lava Beds, a volcanic region which served as a natural fortification. Maj. Gen. Wheaton entered this tract, Jan. 17, 1873, but could not penetrate within three miles of the Modoc stronghold, and after losing 11 killed and 21 wounded, withdrew. Gen. Gillem then took command, but with no greater success. Meanwhile the government appointed commissioners to inquire into the causes of discontent. A conference, April 11, 1873, was broken up by the Modocs attacking the commissioners, killing Gen. Canby and Dr. Thomas, and wounding Mr. Meacham, another of the commissioners. Active operations were resumed, and the Modocs, after a long and stubborn resistance, finally surrendered to Gen. J. G. Davis, about June 1. Captain Jack, Schonchin, jr., and two other Modocs were tried by a military commission and executed at Fort Klamath, Oct. 3. The rest of those captured were, by order of the secretary of war and the Indian commissioner (Nov. 4), placed on the Quapaw reservation, in the Indian territory. This band numbered 148; the number of those left at the Klamath agency who took no part in the war was about 100.

MERRIS, a lake of Egypt, near the ancient Crocodilopolis, now Medinet-el-Fayoom. Herodotus says: "Wonderful as is the labyrinth, the work called the lake of Meris, which is close by the labyrinth, is yet more astonishing. The measure of its circumference is 3,600 furlongs, which is equal to the entire length of Egypt along the seacoast. The lake stretches in its longest direction from north to south, and in its deepest parts is of the depth of 50 fathoms. It is manifestly an artificial construction, for nearly in the middle stand two pyramids, rising to the height of 300 ft. above the surface of the water, and extending as far beneath, each crowned with a colossal statue sitting upon a throne. The water of the lake does not come out of the ground, which is here excessively dry, but is introduced by a canal from the Nile. The current sets for six months into
the lake from the river, and for the next six months into the river from the lake." The same historian ascribes the formation of this lake to a king Moeras who lived about 1350 B.C., and who is identified by modern Egyptologists with Amen-hotep (Amenophis) III., the Memnon of the later Greeks and Romans. But he confounds the natural lake Birket-el-Keroen with the artificial lake Moeras. (See Birket-

It Moaso-Goths, the name middle among early divided Superior and or gists lake months the with artificial water the with the object of its construction.

Moesia (in Greek, Mysia), an ancient country of eastern Europe, bounded N. by the Savus (Save) and Ister (Danube), E. by the Euxine, S. by the Haemus (Balkan) and Scardus ranges, and W. by the Drinus river (Drin). It was divided by the Romans, who conquered it in the early period of the empire, into Moesia Inferior or E. Moesia, the present Bulgaria, and Moesia Superior or W. Moesia, the present Servia, divided by the little river Clabrus (Talbrizta). The original inhabitants were chiefly Thracians, among them the Triballi. Under Aurelian the Dacian colonies were removed there, when the middle part of the province also received the name of Dacia Aureliana. It was occupied by the Goths in the 4th century, who were called Moso-Goths, and who surrendered the territory to the emperor Theodosius I. Slaves settled here in the 6th and 7th centuries.

Moffat, Robert, a Scottish missionary, born at Inverkeithing, Fifeshire, in 1705. He was reared in the Secession church, but his religious associations from 1811 till 1816 were largely with the Methodists of England, where he then lived. He was a gardener, but devoted his leisure hours to study, and in 1815 offered himself as a missionary. He was originally destined to accompany Williams to the South sea, but was finally sent to South Africa. He sailed in 1817, and immediately on his arrival at Cape Town went toNamaqualand, where he entered upon his labors at the kraal of Africaner, a chief whose name had long been a terror to the neighboring districts, but who had lately become an enthusiastic convert to Christianity. Here Moffat labored for three or four years with great success. But the situation being unsuitable for a principal mission station, he set out in search of a better locality, and labored successfully with much promise in the countries to the north and northeast of Cape Colony, and in every place guided the people in the arts of civilized life. He often made tours among barbarous warlike tribes. His remarkable adventures in these journeys are described in his "Missionary Labors and Scenes in Southern Africa" (8vo, London, 1842), which he wrote and published during a visit of several years to Britain, rendered necessary by the state of his health. During his stay there, he also carried through the press a version of the New Testament and the Psalms in the Bhehuan language. He returned to Africa in 1842, and continued there until recently, when he went back to London. He has compiled a "Seenua Hymn Book" (London, 1843), and his "Farewell Services" were edited by Dr. Campbell, and published in 1843. Dr. Livingstone was Moffat's son-in-law.

Mogadore, or Surah, a fortified seaport town of Morocco, on the Atlantic, 130 m. W. by S. of the city of Morocco; pop. about 20,000, many of whom are Jews. The town stands on an eminence, opposite an island of the same name, and is surrounded by a low sandy flat, which at high water is overflowed by the sea. It consists of two parts, one called the cita-

del, inhabited by Moors, and the other called Mellah, by Jews. The town is well supplied with water by an aqueduct. The houses are generally large and flat-roofed. Some of the
MOHILEV, or MOHILEY. See MOHILEY.

MOGIL, or Moglias, Peter, a Russian author, born in Moldavia about 1597, died Dec. 31, 1646. He studied at several of the European high schools, but stayed longest at the university of Paris. He served in the Polish army with distinction, and in 1625 entered a monastery at Kiev. In 1629 he became archimandrite, and in 1638 metropolitan of Kiev, Galicia, and Little Russia. He was the first to introduce in the study of theology at Kiev the developments which it had acquired in the European universities. He improved the courses of study in every particular, obtained permission to erect a printing press, invited many learned men to the academy, settled upon them sources of revenue which had formerly gone to the metropolitan, and gave them his own valuable collection of books. To confirm the views and feelings of the oriental church in opposition to the encroachments of Roman and Protestant elements, Mogila wrote a "Confession of Faith," which was examined and approved by two councils, and, being indorsed by the four oecumenical patriarchs, and by the Russian patriarchs Joachim and Adrian, became the first symbolic book of the eastern church, and has continued to be the standard book in theology. Mogila published also a "Catechism" (Kiev, 1645), and some pamphlets. Many of his dramas were acted by his pupils at Kiev, and that on the nativity of Christ was for a long time very popular.

MOGILS, a corruption of the term Mongols, used in Hindostan to designate the Tartars who repeatedly invaded that country in the middle ages, and who made themselves masters of Delhi in 1526, and placed their leader Baber, a descendant of Tamerlane, on the throne. His successors are known as the Mogul emperors, of whom the most eminent were Akbar (1556-1605), Jehangir (1605-27), and Aurungzebe (1658-1707). During these reigns the Mogul empire comprised nearly the whole of Hindostan, and in Europe the emperor was called the Great Mogul. His authority gradually dwindled till it became merely nominal; the English supremacy was formally established in 1803, and in 1827 the Great Mogul became a titular pensioner of the British crown. The last of the Mogul dynasty, Mohammed Bahadour, being implicated in the sepoys mutiny, was deprived of his title and transported in December, 1858.

MOHÁCS, a town of S. Hungary, in the county of Baranya, on the W. arm of the Danube,

mosques are fine. The chief exports are wool, gum, wax, hides, almonds, honey, ostrich feathers, ivory, and gold dust. The harbor is formed by an island S. of the town, and is the best on the W. coast of Morocco. Mogadore was founded in 1760 by the emperor Sidi Mohammed, on the site of an old Portuguese fort. It was bombarded by the French under the prince de Joinville, Aug. 15, 1844. It suffered also during the war with Spain (1859-60).

MOHAMMED, or Mahomet (Arab, the Praised, or, according to E. Deutsch and Sprenger, the Desired or Promised, in allusion to Haggai ii. 7), the founder of the Mussulman religion, born in Mecca, according to some, Nov. 10, 570, according to others April 20, 571, died in Medina, June 8, 632. His Mohammedan biographers say that his birth was accompanied by miracles; the sacred fires of the Paraclete were extinguished, the palace of the Persian king was shaken by an earthquake, the lake Sawa dried up, and many other prodigies took place. His family (Hashem) belonged to the distinguished tribe of Koreish, were hereditary guardians of the Caaba, and were said to be directly descended from Abraham by his son Ishmael; nevertheless his parents were poor. His father Abdullah, a merchant, died two months after his birth. The orphan was confided for a little more than two years to the care of a Bedouin nurse, Halima, who returned him to his mother in consequence of some advantages which she attributed to evil spirits. At the age of six years he lost his mother, and was carried by a female slave to his grandfather Abd-el-Mottalib. Two years later he lost also his grandfather, and was then adopted by his uncle Abu Taleb, who held the key of the Caaba. With him young Mohammed (in his 9th or 12th year) made journeys through Syria and other countries, and became acquainted with a Christian (probably Nestorian) monk, called by some Babira, by others Serjies, who predicted his future greatness. Another uncle, Zobair, he accompanied on a mercantile trip to southern Arabia, and four years afterward was with him in a campaign against the Beni Kinnan. In his 25th year he was a shepherd near Mecca, and then joined for a short time the business of a linen trader named Sulh, commerce being at that time almost the sole occupation of the higher classes in Mecca. At Hajasha, a market six days' journey S. of Mecca, Mohammed, compelled by poverty,
Mohammed entered the service of a rich widow named Khadijah. Several business journeys which he made for her through Syria and Arabia so pleased her that she determined to marry him. According to the common tradition Khadijah was then 40, and Mohammed a little over 25 years old. After his marriage Mohammed gave up business, and for ten years was chiefly occupied with his family, having by Khadijah four daughters and two sons; both sons died young. From his 35th to his 40th year Mohammed frequently resorted to a solitary cave of Mt. Hara, to give himself up entirely to religious contemplation. There, amid spasmodic convulsions, he had his first vision, in which the angel Gabriel appeared and commanded him to recite what he (the angel) said. Mohammed was troubled as to the nature of his mission, whether it come from an angel or from an evil spirit. His wife consulted her cousin Waraka, "who was old and blind" and knew the scriptures of the "Jews and Christians," and he assured her, and afterward Mohammed himself, that "God had chosen him to be the prophet of this people." The revelations continued henceforth without interruption to the end of his life, and were dictated by Mohammed to several secretaries, committed by his adherents to memory, and after his death collected and written down. (See Koran.) His wife was his first convert. During the first three years of his mission only the relatives and friends of Mohammed acknowledged him as a prophet, and the whole number of believers (Moslem or Moslems) amounted scarcely to 40, among whom were Abubekr and Ali. In the fourth or fifth year of his mission he came forward publicly in compliance with a special message, and proclaimed himself a prophet, but met only with imprecations and ill treatment. To protect him from attempts on his life, he was removed by his uncle Abu Taleb to a fortified castle outside of Mecca, where he remained three years. The Koreishites outlawed him and his disciples. When the interdict, after the expiration of three years, was removed, Mohammed returned to Mecca; and soon after, in the tenth year of his mission, he lost his uncle and protector Abu taleb, who never acknowledged the mission of his nephew. Three days later he lost his wife Khadijah, during whose lifetime he had not taken other wives; after her death he soon married several, nine of whom survived him. Mohammed was again expelled from Mecca, and also from Tayef; but soon he reentered Mecca, greatly strengthened by his celebrated journey to heaven. His relation of the journey, which he called a dream, increased the wrath of his enemies, and caused the defection of some of his adherents. Some pilgrims from Yathreb, belonging to the tribe of Khazraj, were converted in 621, and on their return propagated his doctrines at home. In 622, 73 Moslems from Yathreb appeared at Mecca, and concluded with Mohammed a treaty offensive and defensive. In September of the same year,
tions from various tribes who announced their submission. He proclaimed a holy war against the Byzantine empire, which proved a complete failure, and he was obliged to return to Medina amid the reproaches of the soldiers. In the following year Mohammed made his last pilgrimage to Mecca at the head of at least 40,000 pilgrims. The rites of this pilgrimage have ever since been regarded as the standard rule for pilgrimages. Three months after his return to Medina he was taken seriously ill. He called his wives together, and requested that he might be allowed to remain in the house of Ayesha, his favorite, which adjoined the mosque. He himself announced in the mosque the approach of his death. During the last days of his life he liberated his slaves, caused seven denars to be distributed among the poor, and prayed: “God support me in the agony of death.” He expired in the arms of Ayesha. After a long dispute respecting the place of his interment, he was buried in the house in which he died. This spot lies now within the enlarged mosque. His only surviving child was Fatima, the wife of Ali, and the ancestress of all the sherifs or nobles of the Mohammedan world.—Mohammed is said to have been of middle stature, and to have had a strong beard and thick hair, a noble mien, a brown and lively complexion, brilliant eyes, white teeth, and a modest bearing. He possessed natural eloquence, a keen intellect, an overwhelming fluency, and great courage. Conjugal love he regarded as one of the great incentives to devotion. The wish to have a son to succeed him has been alleged as the reason why he took so many wives. In his infancy as well as in after life he was afflicted with epileptic attacks, which at first were considered by himself and by his enemies to be the effect of demoniacal possession. The same spasmodic convulsions accompanied him while he received his revelations. Mohammed was acquainted with the doctrines of both Jews and Christians, but charged them with having corrupted their Scriptures. He attributed to both of them opinions which they do not hold, but most of these statements may rest on the authority of the apocryphal books of the ancient Christian church. Before the 12th century it was hardly understood in the West that Mahomet was a man, and not a pretended divinity, and still earlier he was known as Maphomet, Baphomet, or Bifum, and believed to be a false god to whom human sacrifices were offered. Later it was common among Christian writers to represent him as a conscious impostor. This opinion has now but few representatives.—Among the Mohammedan biographies of the prophet, those of Wakidi, Ibn Ishak, and Tabari are the most important, and some of them have been translated into French, German, and other languages. Among the best European and American biographies of Mohammed are those of Marracci (Padua, 1698), Gagnier (Amsterdam, 1732), Hammer-
Mohammed IV., a Turkish sultan, born in 1642, died about the close of 1692. In 1648 he succeeded his father Ibrahim I., who had been deposed and strangled by the janizaries. Mohammed Kuprili or Kuperli, an Albanian, was made grand vizier. To him, and to his son who succeeded him, the reign of Mohammed IV. owes all its celebrity. The sultan had neither talent nor energy, and cared little for anything but hunting, in which he spent most of his time, and lavished vast sums. The empire at his accession was in the utmost confusion, but Kuprili restored order by promptly putting to death the leaders of sedition. Ibrahim, at war with Venice, had conquered the greater part of Campania in 1645, and the war continued after Mohammed's accession. The Venetians defeated the Turkish fleet in the Archipelago in July, 1651, and destroyed a second fleet, July 6, 1656, and shortly afterward captured the islands of Lemnos and Tenedos, which the Turks regained in the following year. The contest continued with various fortune till 1667, when Ahmed Kuprili, one of the greatest of Turkish generals, who had succeeded his father as grand vizier in 1661, undertook the siege of the city of Candia, which he prosecuted with vigor for twelves and seven months, when the Venetian commander Morosini was compelled to capitulate, Sept. 16, 1669, while at the same time peace was concluded between Venice and Turkey. In 1660 war had broken out with Austria, and for some time the Turks had been highly successful in Hungary. Germany, France, and Italy combined to check their progress, and Montecuculi, general of the allies, gained a brilliant and decisive victory over them, Aug. 1, 1664, at St. Gothard on the Raab, which, followed by the treaty of Temesvar, put an end to the war. In 1672 the war involved Poland in person, and took Kamenetz; but John Sobieski, then grand marshal of the kingdom, in 1673 gave the Turks a total defeat at Khotin, and in 1676 obtained an honorable peace. An insurrection of the Hungarians under Tokówki tempted the sultan in 1682 to make war again upon the emperor; and in July, 1683, an army of 300,000, commanded by Kara Mustapha, invested Vienna. The emperor fled with his family to Linz. The city was in the last extremity when Sobieski and Charles of Lorraine came to its relief, and on Sept. 12 totally routed the Turks near the battles of Piacenza. After this the Turks met with nothing but disaster. Germany, Poland, Russia, and Venice combined against them; and on Aug. 12, 1687, Charles of Lorraine gave them a terrible defeat at Mohács, which was followed by the loss of Transylvania and other provinces. The Turkish army at length mutinied at Belgrade, marched to Constantinople in the latter part of 1687, dethroned the sultan, and raised his brother Solyman III. to the throne. Mohammed was kept in prison till his death.

Mohammed IV. See Mehemet Ali.

Mohammedanism, the name commonly given in Christian countries to the religion established by Mohammed. The Mohammedans do not themselves acknowledge the name. They call their religion Islam, which means "full submission to God," and themselves Moslems, or "the people of the Islam." Mohammed designated himself as the restorer of the pure religion revealed by God to Abraham. As the messenger of God he required his pagan coun-
try men to leave their idols and adopt the worship of the one true God; the Jews, to exchange the law of Moses for the new and final revelations given to him; the Christians, to cease worshipping Christ as God, as inconsistent with monotheism and with the true doctrine of Christ himself. The doctrines of Mohammedanism may in large measure be traced to the national religion of the Arabs before Mohammed, to those forms of Judaism and Christianity which existed in Arabia in his time, and to those traditions and usages which were the common heritage of all branches of the Semitic race. To what extent Mohammed borrowed from these three sources the profound researches instituted during the last half century have begun to reveal.—The sayings of Mohammed relative to his religion were collected in the Koran, which is recognized by all Mohammedan sects as their rule of faith and morals. (See Koran.) But the great majority of the Moslems recognize, in addition to the Koran, the Sunna, or traditions, embodying the expressions, occasional remarks, and acts of Mohammed, which are traced to his companions, his wives, and the first caliphs. Not only do they regulate, conjointly with the Koran, the doctrines, rites, and ceremonies of the Mohammedans, but the interpretation of the Koran is in a great measure determined by them. There is much uncertainty among the Moslems regarding them; the rationalistic Shiâhis and the extremists among the Shiâhs reject the Sunna altogether; the moderate Shiâhs acknowledge a tradition, but differ with the Sunnis respecting its extent. (See Sunnis, and Sunna.) Among the Sunnis four orthodox schools were distinguished, all established between 740 and 840. They were called, after their founders, Hanifites, Malekites, Shafeites, and Hanbalites. The first and fourth were of little influence; the second prevailed in northern Africa and Spain, and the third in the eastern countries. Their differences were only in discipline. The two principal rationalistic collections were made by Bokhari (died about 870) and Abu Moslim his pupil. An extract from these two and some later collections was made by Hosein ibn Masud (died about 1190), under the title Manabih. It was translated into English, together with a commentary (Mishcat) by Wadi ed-Din Abu Abdallah Mahommed, who lived about 1170, by A. N. Mathews ("Mishcat ul-Manabih, or a Collection of the Most Authentic Traditions," 2 vols., Calcutta, 1809—11). Most of the traditions received by the Shiâhs are contained in the books Hayat ul-Kulub, Haiq ul-Yaqun, and Ain ul-Hayat, written by Mollah Mohammed Bakir Majlisi, a famous Persian divine, who lived about 1650, which were printed in Teheran in 4 vols. fol. In the 8th and 9th centuries the rationalistic school, called by their opponents Montasals or Separatists, gained great strength and influence. Their chief seat was at Bassorah, where they formed an association of rationalistic scholars. They maintained the absolute self-determination of man, denied the eternity of the Koran, and rejected the reality of the divine attributes so far as to divest God of all those characteristics which are the expression of a personal existence. In the 10th century an orthodox school of scholasticism regained the ascendency, and from this time the doctrines and the ethics of the prevailing denomination underwent no other considerable change. The gradual development of Mohammedan doctrines and their relation to the Koran are still subjects of controversy. We give an outline of the system of doctrines and ethics which generally prevails.—The fundamental doctrine of Islamism, and the only one which it is absolutely necessary to profess in order to be considered a Moslem, is: "There is but one God, and Mohammed is his apostle." The idea of God held by Mohammedans does not differ essentially from the Christian, except that they reject entirely the doctrine of the Trinity. They believe that a great number of prophets have been divinely commissioned at various times, among whom six were sent to proclaim new laws and dispensations, viz., Adam, Noah, Abraham, Moses, Jesus, and Mohammed. To the prophets were revealed certain scriptures inspired by God. All of these have perished except four, the Pentateuch, the Psalms, the Gospel, and the Koran. The first three, they maintain, have been falsified and mutilated, and the Koran supersedes them all. Mohammed is the last prophet, and the Koran the final revelation. The Mohammedans regard Christ with a reverence second only to that which they pay to Mohammed, and blasphemy of his name is punishable with death. But they deny that he is God or the son of God, though they consider his birth miraculous. They also deny that he was crucified, believing that some other person suffered in his place, while he was taken up to God. He will come again upon the earth to destroy Antichrist, and his coming will be one of the signs of the approach of the last judgment. The Moslems believe in the existence of angels with pure and subtle bodies created of fire, who have no distinction of sex, neither eat nor drink, and are employed in adoring and praising God, interceding for mankind, keeping a record of human actions, and performing various other services. Four are held by God in peculiar favor: Gabriel, who is employed in writing down the divine decrees, and by whom the Koran was revealed at various times to Mohammed; Michael, the especial guardian of the Jews; Azrael, the "angel of death," who separates the souls of men from their bodies; and Israfil, who will sound the trumpet at the resurrection. There is also a class of beings lower than the angels, like them made of fire, but of a coarser nature, called jinns (generally rendered genii), who eat and drink and are subject to death. Some of these are good, some evil. The chief of the latter is Eblis or "despair," who was once an angel named Azazel, but
who, having refused to pay homage to Adam, was rejected by God, and wanders over the earth until the resurrection. These genii have various names, as peri, fairies; die, giants, fates, &c. In regard to the state of man during the time between death and the resurrection, many different opinions prevail. There are also different views as to the last judgment, but the essential point agreed upon by all is that men will have awarded to them that condition of happiness or misery to which God shall judge them entitled by their conduct and belief during this life. The time of the resurrection is known only to God; its approach will be indicated by certain signs, among which will be the decay of faith among men, wars, seditions, tumults, the advancement of the meanest men to the highest dignities, an eclipse, the rising of the sun in the west, and numerous other portents. After the judgment all must pass over the bridge Al-Sirat, which is finer than a hair, sharper than a sword, and beset on either side with thorns. The good will pass over easily and speedily; the wicked will fall headlong into hell. The delights of heaven are for the most part sensual, made up of pleasures especially suited to each of the senses, while the torments of hell consist chiefly in the extremes of heat and cold. For those who wish more of detail as to their views of the future state, the preliminary discourse to Sial's translation of the Koran is the most accessible work. The Moslems hold that all who believe in the unity of God will finally be released from punishment and enter paradise. Those who deny the absolute unity of God, idolaters, and hypocrites will suffer eternally. To hypocrites they assign the lowest place in hell. They believe in the absolute foreknowledge and predestination of all things by God, and at the same time in the responsibility of man for his conduct and belief.—Their practical religion, which they call din, chiefly insists upon four things: 1, purification and prayer, which they regard as together making one work; 2, almsgiving; 3, fasting; 4, the pilgrimage to Mecca. Prayer must be preceded by ablation; cleanliness is regarded as a religious duty, without which prayer would be ineffectual. The Moslems pray five times each day, soon after sunset (not exactly at sunset, for fear they should be considered sun worshippers), at nightfall (generally about an hour and a quarter after sunset), at daybreak, near noon, and in the afternoon. The times of prayer are announced by the muezzins (mueddzins) from the minarets of the mosques. In praying, the believer must turn his face toward Mecca, and the wall of the mosque nearest that city is marked by a niche. Twice during the night the muezzins also call to prayer, for those who wish to perform extra devotions. Prayers may be said in any clean place, but on Friday they must be said in the mosque. The regularity and devotion with which the Moslems perform this duty are testified to by all who have visited the East. Women are not forbidden to enter the mosque, but they never do so when the men are at their devotions. Before prayer all costly and sumptuous apparel must be laid aside. Almsgiving was formerly of two kinds: legal, called teekah, and voluntary, called sadakah. The former was in reality a tax paid to the sovereign, and by him distributed as he saw fit; it has long since fallen into disuse. The sadakah consists of cattle, money, corn, fruits, and wares sold. It is given once a year, and generally amounts to about 24 per cent. of the stock on hand; but no alms are due unless the stock amounts to a certain quantity, nor unless the articles have been in the owner's possession for eleven months. At the end of the fast of Ramadan every Moslem is expected to give alms if he is able, for himself and each member of his family—a measure of wheat, rice, or other provisions. The Moslems also lay great stress upon fasting. During the whole of the month Ramadan they fast from the rising to the setting of the sun; they neither eat nor drink nor indulge in any other physical gratification. They observe this fast with great rigor, but certain classes of persons to whom the fast would be physically injurious are excused from its observance. There are other days during which fasting is regarded as specially meritorious though not obligatory, and fasting at any time is regarded as peculiarly acceptable to God. The pilgrimage to Mecca, called hajji, is a relic of the ancient idolatrous religion which Mohammed desired to do away with, but which was too deeply rooted in the habits and interests of the people to be abolished. Hence he sanctioned it and made it obligatory, having first destroyed the idols in the temple and introduced new regulations. All Moslems, men or women, should at least once during their lives, provided they are able, make the pilgrimage to Mecca. The duty may be performed by a substitute, in which case the whole merit remains with him who has performed the pilgrimage. This pilgrim is entitled to prefix to his name the word hajji. Of late years the number of pilgrims has greatly fallen off.—The Moslems regard the Koran not only as the rule of their religious but also of their civil and social life. Before the time of Mohammed it was not uncommon among the Arabs to put to death their female children. This practice was forbidden by him. The following things are also forbidden in the Koran: eating of blood, or the flesh of swine, or of any animal that dies of itself, or has been strangled or killed by accident or by another beast, or has been slain as a sacrifice to an idol; playing games of chance, whether with or without a wager; the drinking of wine or of any inebriating liquor, but some construe this prohibition as only applicable to their excessive use, while a few of the very strict construe it as applying to opium, bang, and even coffee and tobacco; the taking of interest upon money lent, even when the loan is
made to a person of a different religion, divination, and various other superstitious practices. Murder seems to be regarded by the Koran as a crime against individuals rather than against society; hence it was punishable with death or a pecuniary fine, at the option of the family of the murdered man. But at present in the Turkish empire murder is punished with death, and commutation by fine is not permitted. If a believer kill another accidentally, the slayer must pay a fine and redeem a believer from slavery. The punishment for theft is cutting off the hand, but in modern times this has generally fallen into disuse, and the baptismado or imprisonment has been substituted. Polygamy existed among all the Semitic nations previous to the time of Mohammed, and he restricted rather than extended it. While claiming for himself special privileges in regard to his domestic relations, asserting that they were allowed him by the direct permission of God, he limited the number of wives which a true believer might take to four. Divorce is very easy in theory, but very rare in practice. The husband has merely to say to his wife, "Thou art divorced." He may receive her back, and again divorce her; but if he divorces her a third time, he cannot take her back until after she has been married to some other man and been divorced by him, or has become a widow. Aside from the domestic relations, the ethics of the Mohammedan religion are of the highest order. Pride, calumny, revengefulness, avarice, prodigality, and debauchery are condemned throughout the Koran; while trust in God and submission to his will, patience, modesty, forbearance, love of peace, sincerity, truthfulness, frugality, benevolence, liberality—indeed, aside from the differences of opinion in regard to theological subjects, all those qualities which the Anglo-Saxon race have idealized under the term "Christian gentleman," are everywhere insisted upon. Mysticism and asceticism were early cultivated by the Moslems, and called forth Sufism, the monachism of the Islam, a phenomenon of the greatest importance for a right understanding of the true character and the bearing of their doctrinal system.—On their first promulgation the doctrines of Mohammed spread with amazing rapidity. In 12 years the whole of Arabia had embraced the Islam. Abubeck, the first caliph, declared war against all nations, especially against the emperors of Constantinople and "the great king of Persia," at that time the two most powerful monarchs of the world. The battle of Bosra opened Syria to the Arabs; and one of the first feats of Omar, the successor of Abubeck, was the conquest of Damascus.Soon afterward a battle near the lake of Gennesaret decided the fate of Syria. Jerusalem capitulated on easy terms, and with brief interruptions has remained subject to the Mohammedans, and is one of their three holy cities. Amru, a general of Omar, completed the conquest of Egypt, and fairly commenced that of northern Africa. On the S. shore of the Mediterranean the Arabs met with little resistance. Soon after the death of Omar, Persia was entered by Khaled, Irak or Assyria was subdued and plundered, the Euphrates together with the gulf of Persia fell into the hands of the Arabs, and Ctesiphon and Faristan, whither the king of Persia had fled, came under Moslem domination. On the appointment of Ali to the caliphate those great internal struggles commenced which have ever since rent the Mohammedan world, without however arresting its external growth. Moawiyah, the rival of Ali, took possession of most of the Persian provinces, and established the Islam in Europe by getting a foothold in Sicily. He was still more fortunate in Africa, and from 697 the whole of northern Africa may be considered as the home of Islamism. At the beginning of the 8th century the Mohammedans, under Abderraham, another one province after another was speedily subdued, and for 800 years the Saracens retained a dominion in that country. A few years later Abderrahman with a force of 400,000 Moslems entered Gaul, but they were defeated in the decisive battle between Tours and Poitiers by Charlema Martel (A. D. 732), which put a final stop to their progress in western Europe. They advanced eastward into China and India; in the former country their progress was soon stayed, but in the latter they founded vast empires on the shores of the Indus and Ganges, which for a long time were strongholds of Islamism. Fresh energy was infused into the Moslem community by the accession of the Seljuk Turks. Being called to his aid by Mohammed ben Jubriel, they seized upon Persia, mastered a portion of the Byzantine empire, and established one of the seats of their government at Iconium or Kony. Having withstood the repeated attacks of the Christian world during the period of the crusades, they were over run by other Tartar tribes, who passed over Persia, Armenia, and Asia Minor, and laid the foundation of the empire of the Ottomans, or Turks properly so called. Both the Seljuks and their successors, the Osmanis, voluntarily received Islamism from the people whom they conquered. The Ottoman rulers gradually undermined the Byzantine empire; Amurat I. entered Europe and made Adrianople his capital; Amurat II. left nothing to the Greek emperor but Constantinople; and Mohammed II. struck the fatal blow, taking Constantinople in 1453. The Ottoman empire, and with it the political power of the Islam, were now at their zenith; the Turks became for many centuries the terror of Italy, Hungary, and Germany, but Christendom soon ceased to suffer any considerable losses by their advance. On the other hand, the Christian nations began to conquer considerable portions of Moslem territory. Sicily had been lost before this period; in Spain their last strongholds were taken in 1492. Greece commenced
its successful struggle for independence in 1821; Algiers was wrested from them in 1830; and the dependence of the Danubian principalities on the Ottoman Porte long since became merely nominal. But Mohammedanism continues to make peaceable conversions in the interior of Africa, where many of the most intelligent tribes and kingdoms have adopted the Arabic faith and culture. Several nations of the Indian archipelago have been converted at a recent period, and in Malabar the Mohammedans purchase or procure children of the lower classes to bring them up in the "true faith." But while the Islam advances among races inferior to the original Mohammedans in point of civilization, its foremost representative among the great nations, the Ottoman empire, lives avowedly at the mercy of the great powers of Europe; Persia and Turkistan have felt the superiority of Russia, and Morocco has been defeated by Spain.—The total number of Mohammedans at the present time is estimated at about 180,000,000. In Europe they are almost confined to Turkey, and even there they form but a fourth of the population, about 4,000,000 out of 10,500,000 (including Roumania), and are constantly decreasing. In European Russia they count about 2,400,000 souls; in Asiatic Russia, 5,000,000. They prevail in Asiatic Turkey, Persia, Afghanistan, Beloochistan, Arabia, and Tartary, and are largely represented in India and the Indian archipelago, and to some extent in China. In India the census of 1872 revealed the fact that the number of Mohammedans, as well as of the total population, had been greatly underestimated. Their number had been placed at 25,000,000, but they are now estimated at 41,000,000. The fact that the Mohammedan religion ignores all distinctions of caste, and at once raises the new convert to full social equality, tends greatly to promote its spread among the Hindoo population. It is believed that in India about 100,000,000 may be set down as Mohammedans. In America and Australia they are not represented at all. More detailed accounts of the several national branches of Mohammedans will be found in the articles devoted to the Mohammedan countries. See also the articles on the Arabic, Persian, and Turkish literatures.—One of the best treatises on Mohammedanism is that of Dollinger, *Mohammeds Religion nach ihrer inneren Entwicklung und ihrem Einflusse auf das Leben der Volker* (Ratisbon, 1838). See also Taylor, "History of Mohammedanism;" Mill, "Mohammedanism" (London, 1817); Arnold, "Ishmael, or a Natural History of Islamism" (1839); "Islam, its History, Character, and Relation to Christianity" (Boston, 1874); and works cited under MOHAMMED.

MOHAVE, the N. W. county of Arizona, bounded N. by Utah and W. by California and Nevada, in which it is separated for the greater part by the Colorado river; area, about 10,500 sq. m.; pop. in 1870, 179. It is intersected in the north by the Colorado, which here enters the Grand Cañon, and in the south by Bill Williams fork. The lower portion of the Colorado valley is from 2 to 10 m. wide, possessing a rich alluvial soil, generally covered with a dense vegetation, and well wooded with mesquite and cottonwood. Parts of the county E. of the valley are rolling and hilly, covered with nutritious grasses and an abundance of timber; but the greater portion is rocky and desolate, seasoned with precipitous canons. Gold, silver, copper, and lead are found in the mountains, and some mining is carried on. Capital, Mohave City.

MOHEAVES, an Indian tribe on the Mohave and Colorado rivers, Arizona, being part of the Yuma nation of the Pima family. They call themselves Amockhavé, and were known to the Spaniards by several names, as the Jamajabs, Cosinas, &c. Their territory extended from lat. 34° to 35°. They are warlike, tall, well formed, and industrious cultivators of the soil. They paint themselves from head to foot with ochre, clay, and charcoal. The men wear little more than a breech cloth, and the women a double apron of strips of bark and vegetable fibre; both sexes wear necklaces of shell; the men exclusively wear eagle feathers, and if wounded, paint blood. Instead of houses they have a great many large tents of mats. The houses are made of logs with a wide shed in front, but some live in mere hovels of brush. They store grain and mezquite beans in circular thatched granaries of osier twigs and very large earthen jars. They have several times come into collision with the United States troops, but are now quite peaceful to the whites, though occasionally at war with the Chemehuevis. They are rapidly declining, being almost all infected with disease. A reservation of 131,200 acres on the Colorado has been assigned to them, but fewer than 1,000 inhabit it. They have lost severely by epidemic diseases, and are now roughly estimated at 840 on the reservation and 2,000 to 3,000 not yet brought in. They have no schools nor missionaries.

MOHAWK, a river of New York, which rises in Oneida co., about 20 m. N. of Rome, from which place it flows S. E. and E. through Herkimer, Montgomery, Schenectady, and Saratoga counties, falling into the Hudson at Water- ford, 10 m. above Albany; length, 185 m. At Little Falls, Herkimer co., and "The Nose," Montgomery co., the river has forced its way through mountain barriers, and flows through deep, rocky ravines; and at Cohoes, 1 m. from its mouth, it falls over a precipice 70 ft. in perpendicular height. During its course it supplies valuable water power. The Erie canal and the New York Central railroad follow its banks as far as Rome. Rome, Utica, Little Falls, Schenectady, Cohoes, and Waterford are the principal towns on its banks.

MOHAWKS. See AGMEGUE.

MOHEGANS, or Mohicans, an Algonquin tribe, found by the Dutch holding both sides of the Hudson river for about 75 m. They received
the Dutch amicably, and gave them lands on which they erected Fort Orange (Albany). They were then at war with the Mohawks, and erected a fort opposite the Dutch. The commandant of Fort Orange, Krieckebecck, accompanied them on an expedition against the Mohawks, but was defeated and killed. In 1625 the Mohicans, attacked by the Mohawks, fled to the Connecticut river. A part of the nation had gone eastward many years before and settled on the Thames, where they were generally known as Pequots, of whom Sassacus was chief; but some of them who seceded under Uncas were called Mohegans. In the war of the English against the Pequots, these Mohegans aided the colonists. The Mohegans of the Hudson, or River Indians, gradually returned to that river. They kept up an occasional intercourse with the French from an early period through the Algonquin tribes in Canada, and were known in French annals as Loups or Wolves, that being the meaning of Mohegan. When the English about 1690 began the great struggle against the French, the Mohegans as a body made peace with the Mohawks, and joined the English with war parties. By 1700 they were reduced to 200 warriors, and the Connecticut Mohegans to 150, 100 of whom were in the service of the colony. In 1788 Sargeant collected some of the latter at Stockbridge, and from 1740 to 1744, the Moravians maintained a Moravian mission at Shekomeko, in Dutchess Co., N.Y., which led some of the Mohegans to remove to the Susquehanna, where they became a distinct element in the Moravian towns. During the revolution the Mohegans joined the Americans, and figured at Bunker Hill, White Plains, and Barren Hill. After the war Samson Occom, an educated Mohegan clergyman, and David Fowler gathered several Indians, chiefly Mohegan and Long Island Indians, who emigrated to New York, and became known as the Brotherton Indians. Those who remained in Connecticut had dwindled in 1842 to 60 or 70. Between 1820 and 1890 the Stockbridge Indians emigrated from Oneida to Green bay; the Brotherton Indians also removed to Wisconsin, where they finally abandoned their tribal relation, and in 1899 became citizens, as did many of the Stockbridges. The remainder of the latter band of Mohegans are with some Munsees on a reservation at Red Springs, numbering about 100. They have almost entirely given up their own language for English. For their language see "Observations on the Language of the Muhekenew Indians," by Jonathan Edwards (New Haven, 1788).

MOHLEY, or Mohler. I. A W. government of European Russia, bordering on Vitebek, Smolensk, Orel, Tchernigov, and Minsk; area, 18,545 sq. m.; pop., in 1867, 908,585. The surface is generally level and the soil fertile. The climate is mild and dry. There are several small lakes and marshes. The principal river is the Dnieper. Bog iron is found in abundance. II. A city, capital of the government, on the right bank of the Dnieper, 312 m. W. S. W. of Moscow; pop. in 1867, 38,922, including many Jews. It is the seat of a Greek archbishop, and of the Roman Catholic archbishop and primate of Russia and Poland, has 4 convents, about 30 churches and 20 synagogues, a gymnasium, a Greek and a Roman Catholic theological seminary, and many manufactories. It is a favorite residence of the Russian nobility. It was taken by Charles XII. in 1708, and recovered by Peter the Great in 1709. A portion of the Russian army was defeated there by the French, July 23, 1812.

MOHL. I. Hugo von, a German botanist, born in Stuttgart, April 8, 1805, died in Tübingen, April 1, 1872. He studied medicine and the natural sciences at the university of Tübingen, and in 1855 became professor of botany and director of the botanic garden. The establishment in 1869 of a special faculty for natural sciences was entirely due to his influence. He published many works, and is one of the highest authorities on vegetable physiology. II. Robert, brother of the preceding, born in Stuttgart, Aug. 17, 1799, professor of jurisprudence at Tübingen and Heidelberg, and prominent as a legislator and diplomatist of Baden, has published, among other works, Die Polizeiwissenschaft nach den grundsätzen des Rechtstaats (3 vols., Tübingen, 1832–4; 5th ed., 1869); Die Geschichte und Literatur der Staatswissenschaft (3 vols., Erlangen, 1855–58); and Staatsrecht, Völkerver und Politik (3 vols., 1860–69). III. Julius, brother of the preceding, born in Stuttgart, Oct. 28, 1800, was extraordinary professor of oriental literature in Tübingen from 1826 to 1832, when he went to Paris, in 1845 became professor of Persian in the college de France, and in 1852 director of the oriental department of the national printing office. He has edited Firdusi's Shah Nameh (3 vols., Paris, 1838–'06), and many Chinese and other oriental works, and written Dante et les origines de la littérature italienne, &c. 

MÖHLER, Johann Adam, a German theologian, born at Igersheim, Württemberg, May 6, 1796, died in Munich, April 12, 1838. He studied at Mergentheim, Ellwangen, and Tübingen, was ordained priest of the Roman Catholic church in 1819, and in 1820 became tutor in the seminary of theology at Tübingen, and in 1822 private lecturer on theology. Before entering on his new office he visited the principal Catholic and Protestant universities of Germany. On his return he began in 1823 a course of lectures on church history, patrology, and canon law, which at once established his reputation. He strongly sympathized with the reformatory movement then agitating the Catholic church of S. W. Germany; he advocated the restoration of communion in both kinds, the abrogation of the use of Latin in the divine service, &c.; but in later years he abandoned these views, and the articles expressing them are not included in the collect-
tion of his minor works published by Dr. Döllinger (Gesammelte Schriften und Aufsätze, 2 vols., Ratisbon, 1859). In 1825 he published Die Einheit in der Kirche, and in 1826 he was appointed extraordinary professor in Tübingen. In 1827 he published Athanasius der Große (2 vols., Mentz), and an essay on sacerdotal celibacy, directed against the liberal Catholic theologians of Baden and Württemberg, followed in 1829 by Fragmenta aus und über Pseudo-Isidor. In 1828-30 he gave a course of lectures on the comparative theology of the Christian churches, a summary of which was published under the title Symbolik, oder Darstellung der dogmatischen Gegensätze der Katholiken und Protestanten nach ihren öffentlichen Bekennnisschriften (2 vols., Mentz, 1828; 7th ed., Ratisbon, 1871; English translation by Robertson, 2 vols., London, 1843). This is regarded as his greatest work. The Protestant theologians maintained that he had represented ideal Catholicism, and misrepresented, at least partly, the doctrinal systems of the reformers. Some of the most distinguished Protestant divines wrote against him; especially Baur (Der Gegensatz des Katholizismus und Protestantismus, Tübingen, 1833; 2d ed., 1836), Marheineke, and Nitzsch. Möller answered them in his Neue Untersuchungen der Lehrgensätze zwischen Katholiken und Protestanten (Mentz, 1854). Baur replied again in the new edition of his work, but the continuation of the controversy was forbidden by the government, and Möller was censured for reviving an obsolete contest. He consequently resigned his professorship at Tübingen, and when the Prussian government offered him one either at Bonn, Breslau, or Münster; he chose Bonn, but subsequently declined when the archbishop of Cologne demanded that he should expressly retract his work on "Unity in the Church." In the spring of 1835 he became the university of Munich, and for three years lectured on the Epistle to the Romans, followed by others on church history and patrology; but his lectures were interrupted by sickness in 1836, and he never fully recovered. In 1838 the king of Bavaria appointed him dean of Würzburg. At the time of his death he was collecting materials for a history of monachism. A large posthumous work on the Christian literature of the first three centuries was edited by Prof. Reithmayr of Munich (Patrologie, vol. i., Ratisbon, 1839). A Catholic biography of Möller, by Reithmayr, is added to the fifth edition of his "Symbolism." The best Protestant biography is that of Prof. Kling of Marburg.

MOHNS, Friedrich, a German mineralogist, born at Gernrode, Anhalt, Jan. 29, 1773, died at Agordo, Venice, Sept. 29, 1839. He was professor at Gratz from 1811 to 1817, when, after accompanying his pupil Count Brenner to England and Scotland, he succeeded Werner as professor of mineralogy at Freiberg, and in 1826 became professor at Vienna. He originated a new system of classification for minerals, which in the grouping of species regarded only their external characteristics. His principal works are Grundriss der Mineralogie (2 vols., Dresden, 1822-'4); English translation with additions by Haidinger, 3 vols., Edinburgh, 1825), and Anfanggründe der Naturgeschichte des Mineralreichs (Vienna, 1832; 2d enlarged ed. by Zippe, 2 vols., 1836-'9).
MOIR, David Macbeth, a Scottish author, born at Musselburgh, Jan. 5, 1798, died in Dumfries, July 6, 1851. He was educated at the grammar school of his native town, and obtained a diploma as surgeon in 1816. He contributed both prose and verse to Constable's "Edinburgh Magazine" and to "Blackwood." He was commonly known as Delta, from the signature Δ to his serious poems. In 1834 he published "The Legend of Genevieve, with other Tales and Poems," and in the same year began in "Blackwood" a serial novel, "The Autobiography of Mansie Wauch." In 1851 he published "The Ancient History of Medicine," and in 1845 "Domestic Verses," which contains some of his best known poems. In 1846 he met with an accident which made him lame for life. In 1851 he delivered in Edinburgh six lectures on the "Poetical Literature of the Past Half Century," which were afterward published. A selection of his poems, with a memoir by Thomas Aird, was published in 1852, and a new and complete edition of his works in 1867. He was the leading physician of Musselburgh till his death, which occurred during a tour of relaxation.

MOIRA, Earl of. See Hastings, Francis.

MOIVRE, Abraham de, a French mathematician, born at Vitry, Champagne, May 26, 1667, died in London, Nov. 27, 1754. Upon the revocation of the edict of Nantes he took refuge in England, and devoted himself to teaching mathematics. He soon became connected with Halley and Newton, was admitted into the royal society in 1697, was elected a member of the academy of sciences of Berlin in 1730, and of the academy of sciences of Paris in 1754. He was one of the committee appointed to decide on the rival claims of Leibnitz and Newton to the invention of the differential calculus. He made many discoveries and improvements in the theory of series and of probabilities, but is best known by the celebrated trigonometrical theorem which bears his name. He survived most of his literary associates, and his subsistence latterly depended upon his solutions of problems relative to games of chance, which he was accustomed to give in a coffee house. Besides memoirs in the "Philosophical Transactions," he published "The Doctrine of Chances" (1718), "Annuities on Lives" (1724), and "Miscellanea Analytica, de Series et Quadraturas" (1730).

MOKANIA, or Mocana. See Atha ben HakeM.

MOLAI. Pietro Francesco, an Italian painter, born at Colosse, near Como, in 1612 or 1621, died in Rome about 1666. He was a pupil of Cesare d'Arpino and Albani. He was one of the best of the Italian landscape painters, and was much employed by Innocent X. and his successor Alexander VII., as also by Queen Christina of Sweden. II. Giambattista, a painter, sometimes erroneously called a brother of the preceding, born in France about 1618, died in 1661. He studied in Paris, and under Albani at Bologna. He excelled in landscapes.

MOIR

MOIRAS, the name of a peculiar, mostly gray sandstone, found abundantly throughout a large portion of the Alpine system. It occurs in masses frequently alternating with beds of conglomerate, and being of a fine, granular texture, is highly prized as a building stone. Owing to the fact of its forming in certain localities one of the characteristic rocks of the tertiary formation, the term molasse, as applied to group, is sometimes used synonymously with tertiary, corresponding to the eocene, miocene, and pliocene of Lyell.

MOLASSES (Fr. molasse), the sirup which remains in the manufacture of brown sugar, after separating from the juice all the saccharine matter that can be made to crystallize to advantage; also the inspissated juice of sorghum and sap of the maple. "Sugar-house" molasses is the sirup which remains in the conversion of brown into refined sugar, and which contains too little cane sugar to require its further treatment. By fermentation and distillation molasses mixed with the skimnings of the sugar boiling is made to produce rum. (See Sugar.) The entire amount of molasses produced in the United States in 1870, according to the census, was 6,598,323 gallons of cane, of which 4,885,150 gallons were the product of Louisiana, 16,050,089 of sorghum, and 921,037 of maple. The production of cane molasses is limited to the southern states, while the cultivation of sorghum is general throughout the country. During the year ending June 30, 1873, 45,583,909 gallons of molasses, valued at $9,901,051, were imported into the United States, chiefly from Cuba.

MOLDAU, a river of Bohemia, which rises in the Bohemian Forest, on the frontiers of Bavaria, flows S. E. as far as Rosenberg, and then N. to Melnik, opposite which town it falls into the Elbe. It is about 300 m. long, and for nearly half its course is navigable. Its chief tributaries are the Luschnitz, Szazawa, Beraun, and Wattawa. The principal towns on its banks are Krummaun, Budweis, Pisek, and Prague. Vessels of 60 tons can ply on it to Prague.

MOLDAVIA (Ger. Moldau; Turk. Bogdan), a country of Europe belonging to the Turkish empire, and now together with Wallachia forming the vassal state of Roumania. It is situated between lat, 45° and 49° N., and lon, 25° and 30° 15' E., and is bounded N., N. E., and E. by Bessarabia, from which it is separated by the Pruth, S. E. by the Black sea, S. by the Bulgarian district of Dobrudja, and W. by Wallachia, being separated from the former by the Danube, W. by Transylvania, and N. W. by Bukowina; area, 18,435 sq. m.; pop. about 1,460,000. It is traversed in the north and west by various offshoots of the eastern Carpathians, through which several passes lead into Bukowina and Transylvania. The principal rivers are the Danube, which during its short course on the S. boundary receives the waters of all the others, the Pruth, and the Sereth. The chief affluents of the Pruth are
the Bakhlu and Shishiya; of the Sereth, the Bistritza, Moldava, Milkov, and Birlat. The largest lakes are between the mouths of the Pruth and Sereth and in the S. E. corner of the country. Moldavia is rich in pastures, and produces wheat, maize, and other grains, excellent melons, various wines, some of which rival those of Hungary, fruits, honey in great abundance, and several minerals, especially salt. The forests contain bears, wolves, and lynxes, and yield excellent timber; the rivers abound in fish. Locusts often appear in destructive multitudes. The inhabitants consist of Moldavians proper, of the Wallach race, Greeks, Armenians, Jews, Osang6-Magyars, Franks, and gypsies. The dominant religion is the orthodox Greek. The general language is the Wallachian, in which the preponderant Latin or Romanic element is largely mixed with Slav, Turkish, and Tartar words. Agriculture, horticulture, and grazing are the principal occupations; manufactures are scarcely developed, and commerce is almost exclusively in the hands of the Greeks, Armenians, and Jews. Wine, honey, wax, cattle, hides, horses, and timber are the chief articles of export. The most important towns are Jassy, the capital, Galatz, Ismail, Fokshani, Roman, Baken, and Botoshan.—In ancient times this country, which at various periods extended beyond its present limits, was occupied by the Gete. Darius Hystaspis invaded it on his expedition against the Scythians. In the latter part of the 1st century it belonged to the Dacian kingdom of Decebalus. Parts of it were attached after his defeat to the Roman province of Dacia. During the great migration of nations it was successively invaded by the Goths, Huns, Bulgarians, and Slavie tribes. The Avars, who became dominant in the 6th century, yielded to the Bulgarians, and these, after a few centuries, to the Khazars, Petcheneras, and others. The latter tribes successfully warred with the Magyars, but dissensions distracted the country, and the introduction of Christianity in the 11th century was almost without effect. Wars with the Greeks depopulated the country, which was soon after invaded by the Cumans. These in their turn were subdued by the Mongols. In the earlier part of the 14th century a strong Wallachian immigration took place from Hungary under Bogdan, who with his son Dragosh established a dynasty of waywodes known in history under the name of the Dragoshites. The country now received the name of Moldavia from the river Moldava. The Greek creed was made predominant. But internal conflicts combined with external to make the long reign of the Dragoshites one of the bloodiest in history. Among the warlike princes of the period was Stephen VI., surnamed the Great, who died in 1504; but his son and successor Bogdan III., was unfortunate in his wars with the Hungarians and Poles, and having also suffered an invasion of the Tartars, he submitted himself to the suzerainty of the Porte. Bogdan's son, Stephen VII., leaned toward the Christian powers; but his successor, Peter VI., allied himself closely with Sultan Solomyan the Magnificent during his expedition against Vienna. Moldavia was now a virtual province of the Ottoman empire, and soon after lost its eastern division, between the Pruth and Dniester, now known as Bessarabia, which was constituted a separate Turkish province. This part was often reannexed and again detached. The suzerainty of the Porte little if at all ameliorated the condition of the distracted country. For some time the boyars exercised the privilege of electing the waywodes; later the sultans were called upon to appoint them. During the latter part of the 17th century and in the 18th, Fanariote Greeks mostly succeeded each other under the title of hospodar or prince. The principal families from which hospodars were selected were those of Cantacuzene, Cantemir, Ducas, Rakovitsa, Mavrocordato, Ghika, and Ypsilanti. Most of the Fanariote hospodars leaned toward Russia, some of them secretly conspiring with Peter the Great and his successors. In the Turko-Russian wars Moldavia was a principal object of contention. In 1707 and 1795 it was successfully invaded by the Russians under Münich. In the first Turkish war of Othman II. it was occupied and organized as a Russian province, but restored to Turkey by the peace of Kutchuk Kainarji (1774), which, however, secured to Russia a kind of protectorate. Soon after, Moldavia, which meanwhile had been robbed of various important places, converted into Turkish fortresses, also lost its northern district, the Bukowina, which was annexed by Austria (1777). The same power afterward combined with Russia for a new attack on Turkey, and Moldavia again became a seat of war. Austria terminated the war by the peace of Sistova in 1791, Russia more advantageously by that of Jassy in the following year. The succeeding Turkish wars were closed by the treaties of Slobosia (1807) and Bucharest (1812), by the latter of which the czar Alexander gained Bessarabia. The Greek insurrection under Ypsilanti was a source of terrible suffering to the province. The treaty of Akerman (1826) restored the right of electing hospodars, for seven years, to a divan of boyars, the Porte retaining the right of confirmation, and Russia its protectorate. The war of 1828 again brought Moldavia, as well as Wallachia, into the hands of the Russians, who occupied it, under Kisseloff, even after the peace of Adrianople (1829), which excluded all Turks from a permanent abode in it, a new statute being elaborated by a commission of boyars. This being confirmed by the Porte, the Russian army left the principalties, and Michael Sturza, a native boyar, was elected hospodar of Moldavia for life. To unite the two principalties, as an independent Dacian or Rouman state, became now the
chief tendency of the national party. Sturdza
often gave unbrage to the representatives of
Russia and a revolutionary outbreak in Wal-
lachia in 1848 was again followed by a Russian
occupation. A new treaty was concluded by
the Porto and the czar Nicholas at Balta Li-
man in 1849, in consequence of which Sturdza
resigned his office, and another boyar, Gregor
Ghika, was elected hospodar for seven years.
The war of 1853-6 destroyed the new basis.
The Russians again occupied the principalities,
but the military events on the Danube and in
the Crimea compelled their troops to evacuate
them, when they were occupied by the neutral
armies of Austria. The peace of Paris in 1856
aggrandized Moldavia with the southernmost
portion of Bessarabia, which was detached
from Russia, and referred the affairs of the
principalities, which were to be united, to a
conference at Paris of the representatives of
the great powers, the Porto, and Sardinia,
which, in August, 1858, finally agreed on a
new plan of organization. Soon after Alex-
ander Conza was elected hospodar for life in
both principalities, which, being an unex-
pected event, as two elections were anticipa-
ted in accordance with the protocol of the
conference, led to new complications. The
influence of France prevailed in favor of the
tendency to national union, and the election
was confirmed by the Porto, and acknowledged
by all other parties. In December, 1861, the
permanent union of the two principalities, un-
der the title of Roumania, was proclaimed at
Bucharest and Jassy. (See Roumania.)

**MOLE**, the name of many insectivorous mam-
imals of the family talpidae, embracing several
genera which agree in having a stout, thick,
clumsy body, without visible neck, no exter-
nal ears, minute auditory foramina, very small
eyes, short limbs, the anterior much the broad-
est and largest, with strong claws, short tail,
and soft, velvety, and compact fur. Moles are
generally distributed over the earth, except in
South America and within the tropics, though
the genera are closely restricted within certain
regions; thus talpa is found only in Europe and
Asia, eulophis and condylura in North
America, chrysorchilus in Africa, and urotri-
chus in Japan and N. W. America. In talpa
(Linn.), the dentition is: incisors 4, canines
none, and molars 2-2, the first of the molars
representing a canine (the upper in front of
the lower), and the last three tuberculate; by
some writers the fourth tooth on each side in
each jaw is called a canine, which would make
the teeth equal in number and alike in kind in
both jaws. The nose is depressed, truncate
at the point; feet five-toed, the soles of the
fore feet turned backward, with toes connect-
ed and strong claws. The European mole (T.
Europa, Linn.) is 5 or 6 in. long, with a tail of
1 in.; the fur is blackish and very fine; the
bones of the fore limbs are very short and
strong, supported by firm clavicles, and end-
ning in a shovelled-shaped hand, strengthened
by the elongated falciform carpal bone, armed
with large claws, and moved by muscles of
great power; the sternum is keeled for the
attachment of the pectoral muscles, the prin-
cipal ones employed in digging their burrows;
the muscles of the head are also powerful as-
sistants in loosening the earth as the animal
pursues its underground passage, preparing the
way by its pointed, movable, hog-like snout.
The senses of smell, hearing, and touch are
very acute. The eyes are two black glittering
points, about the size of mustard seed, con-
cealed and protected by the surrounding skin
and hairs. The popular belief that the mole
is blind is an error; the mole of Greece men-
tioned by Aristotle as blind is either the spe-
cies T. cersa (Sav.), in which there is no visible
ocular fissure, or perhaps a burrowing rodent
or rat-mole (genus spalax, Guld.), in which
the very small eyes are hidden under the hairy
skin. The openings of the ears and mouth
may be closed by membranous folds to prevent
the entrance of earth; the vent is considerably
prolonged upon the tail. Four or five young
are produced at a time, twice a year, in spring
and autumn. The food consists of worms, in-
ssects, and tender roots, in search of which it
burrows in the ground; these excavations also
serve as places of residence and as highways
of travel from one field to another; its abode
is in some firm hillock in a secure situation, in
which are two circular galleries connected
by a chamber excavated in the centre of the lower
gallery; these communicate by intricate pas-
sages with the high road, through which the
animal passes with considerable speed, though
very slow-moving on the surface of the ground;
the road is placed at a depth of from 3 to 14
in., according to its exposure to pressure from
above. The mole frequently comes to the sur-
face to get rid of the loosened earth; it is very
voracious, and is soon killed by hunger; it is
active all winter, though at a depth of a foot
or more, and in summer at night frequently
seeks its prey at the surface; it is a good
swimmer; when irritated it bites severely, and
the males in the love season often engage in deadly combats. The colors vary; individuals are seen of white, ash, or fawn color. The soft fur is manufactured into light robes and very fine hats, and has been employed for artificial eyebrows. The mole is frequently very detrimental to cultivated lands, but the loss is more than counterbalanced by the destruction of noxious insects and weeds. — The golden moles of Africa (chrynochilus, Lacép.) have incisors $\frac{1}{2}$, the middle lower ones small and narrow, and molars $\frac{3}{2}$; the eyes are covered by skin, nose naked and leathery, fore feet four-toed, with fourth toe very small, hind feet five-toed, and no tail. The best known species (C. Capensis, Desm.) is brownish with green and golden reflections; it inhabits the Cape of Good Hope, and has the form, size, and habits of the mole. — The star-nosed mole of North America (conylura, Illiger) has the end of the nose surrounded by 22 movable fleshy radiating filaments, which serve as delicate organs of touch; the incisors are $\frac{1}{2}$, the upper middle ones broad, the lower ones procumbent, canines $\frac{3}{2}$, molars $\frac{3}{2}$; eyes very small; feet five-toed; tail moderate, thinly haired. The C. cristata (Desm.) is about 4 in. long from tip of nose to base of tail, the latter being 3 in. more; it has the general form of the moles; the hands resemble those of ter-rapins, and with the hind feet (considerably larger) are furnished on both surfaces with a covering of brown scales, with a horny tubercle on the inner edge of the soles; the under surface of the fingers is extended into fringed horny processes. The fur is rather coarse, and sooty brown. It is found in the north-

and molars $\frac{1}{2}$–$\frac{3}{2}$. In the common mole (S. aquaticus, Cuv.) the teeth are 86, the eyes not covered by integument, tail nearly naked, and feet fully webbed; the color is dark plumbeous, with sometimes a brownish tinge, and the feet and tail are white; it is between 4 and 5 in. long, with the tail about an inch; it is found from Canada to Florida, and as far west as the Mississippi. — The genus urotrichus (Temm.) has incisors $\frac{1}{2}$, canines $\frac{3}{2}$, and molars $\frac{3}{2}$; the muzzle is prolonged into a cylindrical tube terminating in a naked bulb; tail short and hairy. A common species in Japan is the U. talpoides (Temm.), smaller than the common mole. A species (U. Gibbesii, Baird), 2½ in. long, occurs in Washington territory.

**Mole, Louis Mathieu**, count, a French statesman, born in Paris, Jan. 24, 1781, died Nov. 23, 1855. His father, president of the parliament of Paris, lost his life during the revolution, and the son passed most of his childhood with his mother in Switzerland and England. Returning to France in 1796, he studied at the central school of public works (now polytechnic school), and in 1806 published his És-sais de morale et de politique, defending monarchical theories in politics. Napoleon appointed him auditor and soon afterward master of requests in the council of state. In 1807 he was made prefect of the department of Côte-d’Or, subsequently became councillor of state and director general of roads and bridges, and in 1813 received the appointment of grand-juge and the titles of count of the empire and commander of the order of réunion. While Napoleon was absent with the army, Molé acted as one of the council of regency, and attended the empress in her flight to Blois on the approach of the allied armies in 1814. By advice of the emperor, Molé gave in his adhesion to Louis XVIII., and was called to the municipal council of Paris. On Napoleon's return from Elba, though he refused to sign the declaration of the council of state against the Bourbons, he retained his office of director of roads and bridges, and was made a peer of France. On the second restoration he was renominated to the council of state and con-

**Mole**.
firmed in his peerage; but he had little influence in the government. In May, 1817, he became minister of marine in the cabinet of the duke de Richelieu. Resigning in December, 1818, he remained out of office until the accession of Louis Philippe, who appointed him minister of foreign affairs, Aug. 11, 1830. The ministry, consisting of a coalition of parties, held together less than three months; but in September, 1836, Molé became again minister of foreign affairs and premier. He negotiated the marriage of the duke of Orleans, and procured an amnesty for political offenders; but after twice dissolving the chambers, he was forced to resign in March, 1839. In the following year he was chosen a member of the French academy. During the revolution of 1848 he withdrew from public affairs, but without solicitation was chosen to represent the department of Gironde in the constituent assembly, where he placed himself among the leaders of the right. He was a member of the committee which framed the law of 1850 against universal suffrage, and was one of those who protested at the mairie of the 10th arrondissement against the coup d'état of Dec. 2, 1851. The close of his life was passed at his ancestral château of Champlatreux. He was one of the staunchest supporters of the Roman Catholic church in France.

MOLE CRICKET, a jumping orthopterous insect, of the genus Gryllotalpa (Latr.), meaning cricket mole. The European mole cricket (G. vulgaria, Latr.) has a most extraordinary and ugly form; it is nearly 2 in. long and ¼ of an inch wide, and of a dark brown color; the head, retractile within the prothorax, has two long and strong antennae in front of its black reticulated eyes; the thorax is elevated and crab-like, covered with a velvety down; the wings, which when expanded are broad and triangular, when folded extend like two ribbons over the abdomen; the abdomen, soft and with nine or ten segments, has two filaments at the end as long as the antennae; the fore legs are short, broad, and strong, the shanks being very wide, flat, and three-sided, with four finger-like projections on the lower side, giving very much the appearance and the digging powers of the hands of the mole, whence the generic name. It lays 200 or 360 eggs in June in a gourd-shaped hollow in the earth, about 2 in. long, having a winding communication with the surface; the young are hatched in five or six weeks, and resemble black ants, not arriving at maturity till the third year; both young and old commit great ravages by feeding on the tender roots of grass, culinary vegetables, and flowers; they also eat insects and worms, and themselves furnish food for moles, lizards, snakes, and other insectivorous animals. The moles emit a pleasing sound at night, at which time they are the most active. Rosel says this insect can push forward on a level surface a weight of 6 lbs. with its fore feet. They rarely appear on the surface, but their presence may

be known by the withered patches in the field and garden, and their retreats detected by the little hills of fresh earth, smaller than those of moles, which they throw up in soft and moist places. Late in autumn they bury themselves deep in the ground, coming again to the surface in the warm days of spring. The surest way to prevent their depredations is to dig up the nests and destroy the eggs; another way is to

pour boiling water into their holes. The American species (G. borealis) is about 1½ in. long, of a bright bay or fawn color, with the wing covers not half the length of the abdomen, and the tips of the folded wings extending only one third of an inch beyond the covers. The G. didactyla (Latr.), having only two finger-like projections on the fore legs, has proved very destructive to the sugar cane in the West Indies and South America.

MOLECULE (Fr. molécule, diminutive of Lat. molea, a mass), a small mass of matter. The word came into use in France in the early part of the last century, and was adopted by Buffon in describing his remarkable theory of the constitution of organized beings. Later it was used by Laplace in his Système du monde, and also by Lavoisier, Foureroy, and other chemists, at the period of the French revolution. The writers of this period distinguished between molécules intégrantes and molécules constituantes. By their definitions the former were simply small particles differing from a mass of the same substance only in magnitude; the latter were the more minute particles of the elementary substances, of which the former may be regarded as composed. The molécules constituantes corresponded very closely to the atoms of modern chemistry, and by more recent authors the words molecule and atom were frequently used as synonymous. Into the English language the word molecule does not seem to have been readily received. Although the organic molecules of Buffon are referred to by Paley, the word is not found in Johnson's dictionary, and was not generally used by English writers on chemistry and physics until within a few years. Indeed, in England the influence of Dalton's theory has given such authority to the word atom that it is still frequently used to denote both the true chemical atom and the physical molecule, and it is therefore the more important for us to carefully distinguish between them.—The term molecule, as used in the modern schools of physics and chemistry,
implies more than the molecules intégrantes of the French writers just referred to. The molecules of a substance are not merely small particles of that substance, but they are isolated masses, or, to use the words of Sir William Thomson, "pieces of matter of measurable dimensions, with shape, motion, and laws of action, intelligible subjects of scientific investigation." The term therefore involves the conception that the molecules of a substance are as definite magnitudes as the stars, and that every mass of matter is a collection of such bodies, just as a stellar cluster is a collection of suns. The molecules of any one substance, however, are supposed to be alike in all respects. There are many phenomena, both of physics and chemistry, which indicate that this conception is just and accurate. We will only refer to two of the most familiar. When boiling under the atmospheric pressure water changes into steam, it expands, as compared with its volume at the point of maximum density, 1,700 times; or in other words, one cubic inch of water yields nearly one cubic foot of steam. Two suppositions are possible as modes of explaining this change. The first is, that in expanding the material of the water becomes diffused through the cubic foot so as to fill the space with the substance we call water as completely as before, and leaving no space within the cubic foot which does not contain its proper proportion of water. The second is, that the cubic inch of water consists of a certain number of isolated particles, the cubic foot of steam containing the same particles as the cubic inch of water, and the conversion of the one into the other depending simply on the action of heat in separating these particles to a greater distance. Hence the steam is not absolutely homogeneous; for, if we consider spaces sufficiently minute we can distinguish between such as contain a particle of water and those which lie between the particles. These assumed particles, which are thus supposed to be separated by the heat, are the molecules of the water; and the molecular theory of the constitution of matter explains the change of volume in the manner last described. That this is probably the true explanation will be evident from a consideration of the familiar phenomena which appear when by pressure we condense steam back to water. Conceive of a cylinder filled with rarefied steam at some temperature above the boiling point of water. If into such a cylinder we press a piston, the volume of the steam will be diminished in proportion to the pressure, according to the well known law of Mariotte, up to a certain limit; but as we increase the pressure a point will be reached, sooner or later, at which this law of compression ceases abruptly, and the steam without any intermediate transition takes a volume many hundred times less than before, changing into a dense mass of liquid water. Now, if there was a perfect continuity in the steam, we cannot conceive why there should not be a similar continuity in the law of expansion; and on the other hand, this sudden break is perfectly explained if we are really crowding together a mass of impenetrable particles, and the whole order of the phenomena suggests this conception. Again, if the space occupied by a mass of steam is really packed close with the material we call water, if there is no break in the continuity of this aqueous mass, we should expect that the vapor would fill the space to the exclusion of everything else, or, at least, would fill it with a certain degree of energy which must be overcome before any other vapor could be forced in. But the facts are the very reverse of this. Conceive of two globes at some temperature above the boiling point of water, one filled with steam, the other completely exhausted. Let these globes be so arranged that we can introduce into each the same quantity of alcohol, and we shall find not only that the alcohol will evaporate in both, but that just as much alcohol vapor will form in the globe filled with steam as in the vacuous space, and will exert precisely the same pressure against the sides of the two vessels. The presence of the steam does not interfere in the least degree with the expansion of liquid alcohol into alcohol vapor. The only difference which we observe is that the alcohol expands more slowly into the aqueous vapor than it does into a vacuum. The final result however is the same in both cases, and thus we may have two different vapors filling the same space without interfering with each other; and more than this, so far as we know, any number of vapors, which do not act chemically on each other, may occupy the same space at the same time, each preserving its individuality so completely that its relations would not be essentially altered if the associated materials were removed. Evidently the vapor completely fills the space which it occupies, although equally distributed through it; and we can give no satisfactory explanation of the phenomena of evaporation except on the assumption that each substance is an aggregate of particles or units, by which the action of heat become so widely separated that they leave very large interstices in which the particles of an almost indefinite number of other vapors can find room.—A study of the phenomena of evaporation leads to a definition of molecules, which, although not comprehensive, is for the cases it covers the most precise that can be given: Molecules are those small particles of a substance which are not subdivided when the body is expanded by heat, and which move as units under the influence of this agent. As the above statement implies, the modern molecular theory assumes, not only that the molecules are isolated masses, but also that they are in active motion, and the phenomena of heat are regarded as manifestations of this motion. The idea that the ultimate particles of matter are in motion is as old as Democritus, but this idea was never precisely formulated.
MOLECULE

until modern times. Now, however, it is one of the most pregnant theories of science; and it is evident that such motion, if it exists, must be a most important factor in nature. The circumstance that these molecular motions are limited by the boundaries of the mass of matter to which the molecules belong, and that the system remains in equilibrium with relation to external objects, because the amount of motion in opposite directions is usually equal, must not of course affect our estimate of the moving power, and this power is no less than that which would be shown in a motion of translation of the same mass with a velocity equal to the mean velocity of the several molecules; and, since the facts compel us to assign to this velocity a value commensurable with the velocities obtained in artillery practice, it is evident that the total moving power, even in a small mass of matter, must be enormous. There are conditions, however, under which the molecules may communicate their motion to masses and thus produce mechanical effects; and our theory refers the tension of aëriiform matter, and the mechanical work which it may be made to do, to the bombardment of the sides of the containing vessel by molecular projectiles. In a solid or a liquid it is assumed that the extent of the motion of the molecules is limited by internal forces, but in a gas this motion is supposed to be unrestrained, so that the molecules beat freely against any surface with which the aëriiform mass may be in contact, and thus the molecules of water in the cylinder of a steam engine produce their well known effects. — The molecular theory has established on a firm foundation the great physical doctrine of the conservation of energy, by explaining a class of phenomena which, as viewed by the old physicists, were apparently wholly at variance with this truth. When two elastic billiard balls strike each other, although the balls may change their velocities, the total moving power will be nearly the same after the collision as before it; but when two inelastic balls of lead strike, there is always an apparent destruction of motion. It was no answer to say that the power which had disappeared as motion had done its work in changing the shape of the balls; for since these bodies cannot recover their figure, and therefore have not the potential energy of elastic bodies under the same conditions, there must be an annihilation of power if the external phenomena are the only effects produced. But if, as our theory assumes, the motion is simply transferred from molar to molecular masses, all is clear; and since we have been able to prove that the change of temperature produced in the masses is the exact mechanical equivalent of the motion lost, we think we are justified in concluding that the effects ascribed to what we call heat are simply manifestations of molecular motion. — When we come to conceive of matter as consisting of elastic molecules which are ever in motion and colliding with each other, we see that motion must be readily communicated from one part of such a system to another; that any excess of energy acquired by any part must be rapidly dissipated; and that the tendency must be to bring all the molecules to the same condition. Moreover, we see that the motion must spread not only through the molecules of the same body, but also from one body to another; for everywhere in nature the atmosphere or some other medium furnishes lines of molecules along which the energy can pass. Now exactly this is true of heat. When a heated body is brought into a room, the heat immediately begins to spread through surrounding objects, and the process goes on until all are reduced to what we call a uniform temperature, that is, to a condition in which there is no tendency of heat to pass from one to the other; and we must remember that our knowledge of temperature and our means of measuring it depend wholly on this motion of heat. We say that one body has a higher temperature or is hotter than another, if when brought in contact heat passes from the first to the second; and we measure the temperature of a body by bringing in contact with it a thermometer, a small bulb filled with mercury, whose narrow neck enables us to detect the slightest change in the temperature of the enclosed liquid. As this volume increases when the mercury is heated, and diminishes when it is cooled, a fixed position of the mercury column indicates that the thermometer is in equilibrium with the body to be tested, and then the artificial scale enables us to compare its thermal condition with freezing and boiling water. — Consider next what must be the mechanical condition of the molecules of two bodies at the same temperature, that is, in thermal equilibrium. The molecular theory assumes that all the molecules of the same substance are alike in every respect, and therefore have the same weight; and hence, in considering the mutual action between different portions of the same substance, we have to deal solely with the collision of small elastic masses of equal weight. Now it follows from the well known laws which govern the collision of elastic bodies, that by the exchanges of velocity which follow each collision the different portions which we are considering would soon be reduced to a state in which the mean velocity of the molecules in each part must be equal. Of course the mutual interchange of velocities must continue after the equilibrium is established, but the loss and gain on either side are then exactly balanced. It follows from this that when two portions of the same substance are in thermal equilibrium, that is, at the same temperature, the molecules of each portion have the same mean velocity. It will be seen however that, although the molecules of a substance in a state of thermal equilibrium have a certain constant mean velocity, the velocity of the individual molecules may vary
MOLECULE

very greatly. Indeed, this must result from the fortuitous collisions, which will cause velocity to accumulate sometimes in one molecule and sometimes in another, while contiguous molecules suffer a corresponding loss.—When we come to consider next the mutual action between masses of different substances, consisting therefore of unlike molecules having different weights, the problem becomes more difficult, because we have now to deal with the collisions of unequal masses. Still the same laws as before give us the key to the solution; and it has been shown by Maxwell and Boltzmann that in all cases, when the condition of equilibrium is reached, the mean value of the moving power of the molecules of any masses must be equal. That is, in general, when any two bodies have the same temperature, 

\[ \frac{1}{2} m V^2 = \frac{1}{2} m' V'^2, \]

\( m \) and \( m' \) representing the weights of the several molecules of the two bodies, while \( V \) and \( V' \) represent the mean of the squares of the velocities in each system. If the molecular weights are equal, then of course the mean velocities must be equal, as just stated; but if the weights are unequal, then the lighter molecules will have on the average a greater velocity. In any case \( V : V' = \sqrt{m'} : \sqrt{m} \); and since we can determine the relative values of the molecular weights, we can calculate the ratio between these mean values of the molecular velocities, assuming of course that the two substances compared are of the same temperature. For example, as the molecules of oxygen gas are 16 times heavier than those of hydrogen gas, the mean value for the velocity of the hydrogen molecules at any given temperature will be four times as great as that for the oxygen molecules. It thus appears that temperature is a condition determined by molecular motion, and that the mean value of \( \frac{1}{2} m V^2 \) is the same for all bodies at the same temperature, a definite value corresponding to each temperature, and becoming greater or less as the temperature rises or falls. This product is the true measure of temperature, and, as will soon appear, this measure corresponds to that obtained with an air thermometer.—We know as yet but little in regard to the molecular structure either of solids or liquids, but the three great laws which define the ætherial condition of matter may be shown to be necessary consequences of the mode of motion which our theory assigns to the molecules of gases. Gas molecules, as we have seen, move with perfect freedom until their motion is altered by collisions either with each other or against some surface; and our theory refers the pressure of a gas against the surfaces with which it is in contact to a very rapid succession of small impulses which produce the effect of a continuous pressure. Now if a mass of oxygen, for example, is confined in a vessel, each of the oxygen molecules must on an average strike the sides of the vessel the same number of times; and so long as the temperature is constant, it must strike with an impulse of the same average momentum. Hence each must contribute an equal share to the whole pressure, and this pressure must be proportional to the number of oxygen molecules in the vessel, or in other words to the density of the gas. Next let us assume that we have two similar vessels of equal capacity containing different gases, both at the same temperature and tension, one filled for example with hydrogen and the other with oxygen gas. According to our theory, if the temperatures are the same, the moving power of the hydrogen and oxygen molecules must be the same; that is, \( \frac{1}{2} m V^2 = \frac{1}{2} m' V'^2 \), as above. Hence \( m V : m' V' = V : V' \), or the momentum of the two kinds of molecules, which is the measure of the pressures they exert, must be inversely proportional to their respective velocities. But, on the other hand, the swifter molecules will strike the sides of the vessels a greater number of times in a second, the number of impulses in a given time being proportional to the respective velocities; or \( m : m' = V : V' \). Hence, \( m m' = m' m' V' \); that is, each molecule of hydrogen will produce in a given time the same effect as each molecule of oxygen, the less momentum being compensated by the greater frequency of the impulses. But if the molecule of hydrogen thus becomes the mechanical equivalent of the molecule of oxygen in producing pressure, then the same effect can be produced in the two vessels only by the same number of molecules. In other words, equal volumes of two gases at the same temperature and tension must contain the same number of molecules; and this is the very important law first announced by Avogadro and afterward confirmed by Ampère.—Next consider what must be the effect on a confined mass of gas of an increase of temperature. Assume that we begin with a closed vessel filled with air at the temperature of melting ice, and with a tension measured by a column of mercury 273 millimetres high in a connecting barometer. An increase of temperature will augment the velocity of the molecule, and the effect of each molecular impulse upon the exposed surface of mercury will be increased in proportion to the velocity; but besides this, each molecule will now strike the mercury a greater number of times in a second, greater again in proportion to its velocity, so that the part of the pressure due to each molecule will vary as the square of the velocity. As the total effect is but the aggregate of these molecular impulses, and the number of molecules acting is assumed to be constant, it is evident that the mercury column, which is the measure of the pressure or tension of this confined gas, must rise in proportion as the product \( \frac{1}{2} m V^2 \) increases; and since, as we have seen, all gas molecules are mechanically equivalent, the effect must be the same whether our vessel be filled with air or with any other gas. Now this product is our theoretical measure of temperature, and the
assumed apparatus is a possible form of air thermometer, which is the most accurate measure of temperature we employ; and thus it appears that our best practice is in harmony with our theory. Evidently, if we could reduce the temperature of the confined gas indefinitely, we should at last bring the molecules to rest. They would then exert no pressure, and the mercury column in our barometer would fall to its lowest level. This condition would be theoretically the absolute zero, and our air thermometer shows what the relation of this point must be to our ordinary standard of temperature, the centigrade scale.—Beginning with the apparatus in the condition described above, the temperature of the air being that of melting ice or 0° C., and the tension 273 millimetres, let us heat it to the temperature of boiling water, 100° C. We know, from experiment, that if the observation of the air is kept constant the mercury column, which measures the tension, would rise to 760 millimetres. Hence, under the conditions assumed and according to our method of graduating thermometers, each centigrade degree corresponds to one millimetre in the height of this mercury column. If the instrument is now cooled through 100° C., that is, if the temperature is reduced again to 0° C., the mercury column will of course fall 100 millimetres; and therefore if cooled 273° C., that is, 273° below the centigrade zero, the tension should become nothing. Or if, according to our mode of estimating temperature by the air thermometer, we define a centigrade degree as a difference of temperature, which at any part of the scale determines in a confined mass of gas a difference of tension equal to \( \frac{1}{273} \) of the tension at the temperature of melting ice, then the absolute zero of heat is at \(-273°\) on the scale so defined. Such a definition, however, gives us no positive knowledge of the relation of the absolute zero to natural phenomena, as a simple consideration will show.—Starting from the self-evident proposition that the quantity of heat liberated by burning fuel under constant conditions is proportional to the amount of fuel burned, we may use the weight of some combustible of constant nature, like hydrogen, as a measure of quantities of heat. Now taking the case we have assumed of a confined mass of air having a tension of 273 millimetres at the temperature of melting ice, we can say in general that, as far as accurate observations have been made, equal increments of heat measured by the fuel standard cause equal increments of tension, and equal decrements of heat equal decrements of tension. Moreover, it would be possible in a given case to calculate from experimental data, at least approximately, the amount of combustible which would be required to increase the tension of a confined mass of air one millimetre; and the theory of the air thermometer, our standard of temperatures, is based on the conclusion that twice this amount of combustible would increase the tension two millimetres, three times the amount three millimetres, and so on. If this is true indefinitely, and if the tension actually increases or diminishes by a constant quantity, through all parts of the scale, on the addition or subtraction of the same quantity of heat (measured by the fuel standard), then we have real knowledge of the relations of the absolute zero. We can say of a mass of air here that it contains as much heat as would be generated by burning a given weight of hydrogen gas, and that if this limited amount of heat were removed its temperature would be reduced to absolute zero. But unfortunately the accurate experiments on the expansion of gases by heat have been confined within such narrow limits of temperature, and our means of connecting the observed effects with the amount of fuel burned, the only legitimate measure of thermal differences, are so indirect, that we must generalise very cautiously; and it is possible that the law to which our observations appear to point would totally fail when the differences of temperature become extreme. Still there are several independent phenomena which seem to confirm this law, and indicate that the absolute zero, as defined above, is a reality and not an assumption. But even as an assumption the absolute zero is on many accounts a more convenient point to count from than the temperature of melting ice. By adding \( \frac{273}{2} \) to temperatures expressed in centigrade degrees, we obtain what we may call the absolute temperature; and we find by experiment, as our theory requires, that the tension of a confined mass of any gas is proportional to the absolute temperature thus expressed. This is a modern way of expressing the law discovered by Charles that equal changes of temperature cause the same relative changes of volume or tension in all aeriform bodies. Thus is it that the molecular theory, and indeed predicts, the mechanical condition of aeriform bodies. We have only been able to give the general features of the reasoning. The mathematical demonstration of the several theorems is based on a beautiful application of the doctrine of averages in the calculus of probabilities, and for this we must refer the mathematical reader to the classical works of Clausius.—Let us next consider some of the qualities or relations of molecules of different kinds, which can be deduced by a similar course of reasoning. In the first place, it is evident that if equal volumes of two gases contain the same number of molecules, the relative weights of these molecules must be the same as the relative weights of the equal gas volumes. Thus, a cubic centimetre of oxygen weighs 16 times as much as a cubic centimetre of hydrogen under the same conditions; and if there is in each cubic centimetre the same number of molecules, each molecule of oxygen must weigh 16 times as much as each molecule of hydrogen. In general, the number which expresses the specific gravity of a gas with reference to
hydrogen, expresses also the weight of a molecule of that substance with reference to the hydrogen molecule. It must be remembered moreover that as the molecule of hydrogen is a definite mass, its weight must be a definite quantity, however small, and may therefore be used as a standard of weight like a grain or a gramme. When therefore we determine the specific gravity of a gas with reference to hydrogen, we thereby determine the weight of a molecule of that aëroform substance in terms of this molecular unit. For reasons based on chemical relations we have actually adopted as the unit of molecular weight one half of a hydrogen molecule, which we call a hydrogen atom; and hence in the system in use the molecular weight of a substance is equal to twice its specific gravity in the state of gas referred to hydrogen. As this unit of molecular weight, although a magnitude of a very different order, is as definite a mass of matter as a grain or a gramme, we shall aid our conceptions by giving to it a definite name; and since the mass of a cubic decimetre of hydrogen has been called a crith, the word microcrith will suggest both the nature of the molecular unit and the order of its magnitude. Remembering then that the microcrith is the weight of the hydrogen atom, and that this is one half of the hydrogen molecule, we shall be understood when for the future we estimate molecular weights in microcriths.

In the second place, it is evident that the known pressure which a gas exerts against the sides of the containing vessel gives data from which we can calculate the mean velocity of the molecular motion under determinate conditions. Consider for example a cubic metre of hydrogen gas at the temperature of melting ice and under a pressure of one atmosphere. This aëroform mass weighs 0.08954 of a kilogramme, and exerts a pressure of 10,382.96 kilogrammes against each face of the cubic enclosure. This pressure balances the molecular bombardment, and the momentum of the bombardment thus resisted during one second must be equal to that which the pressure would produce during the same period if acting on a mass of matter free to move. If the force of gravity at the place of observation imparts to one kilogramme of matter a velocity of 9.8088 metres a second, then this momentum must be equal to 9.8088 x 10,382.96 =101,354. To find the momentum of the molecular bombardment against the cube face, we must conceive of the mass of hydrogen divided by planes parallel to the face in question into very thin sections, which are not thicker than the length of the mean path of a molecule, and between which the motion may be regarded as uniform. Let V represent the mean velocity of the molecules, moving of course in all directions, and u one of the components of this velocity resolved perpendicularly to the face of the cube we are considering, and estimated of course as so many metres a second. Limiting our attention to this component, it is evident that we may regard the whole number of the hydrogen molecules within the enclosure as moving at any instant with the mean velocity u on lines normal to the face of the cube we are considering, and directed either toward this face or its opposite; and, since equilibrium is maintained, it is evident that the two opposite molecular volleys must be equal to each other. It it also further evident that the pressure against the face of the cube must be the sum of these two molecular streams, that from the face as well as that toward it. If the molecules moved only one metre each second, it is manifest that each molecule would on the average move through the length of the cube in a second, were it not that the direction of its motion is continually being altered by collision with other molecules. But although the path of any one molecule may be very short, yet, as the molecules perfectly transmit their motion at each collision, and as the motion is always carried forward by a series of perfectly similar masses, the result is the same as if the same one had moved through the whole distance. There is therefore constantly passing between the small sections we have assumed and also beating against the opposite faces of the cube, the same number of molecules as if the two streams were continuous. If the velocity were only a metre a second, there must pass every section in one or the other direction, and beat against one or the other of the two opposite faces of the cube during each second, a number of molecules, which we will represent by n, equal to the whole number of molecules in the cube; and since the velocity we are considering is u, the number of molecules thus passing on striking must be nu. If now m represents the weight of each molecule, then the total momentum resisted by the cube face each second must be muu*, which is equal, as we have before seen, to 101,354. But in the expression mnu* =101,354 the value mn is simply the weight of the cubic metre of hydrogen at the temperature of melting ice and at a pressure of one atmosphere, or 0.08954 of a kilogramme; so that u* =101,354 +0.08954 =1,181,940. It must be remembered, however, that u is only one of the components of the molecular velocity, that perpendicular to one pair of the cube faces; and in order to determine the actual velocity, V, we must take into consideration the other two components, which are normal to the other two pairs of the cube faces; for \( V = u' + v^2 \). Now, although the values of these components for individual molecules may vary between the widest limits, yet their average values must be equal; for otherwise the pressure of the gas could not be, as it is, equal in the directions of these components. If then our letters represent these average values, \( V = u'' + v^2 \), resolved, and \( V = 1,840 \) metres a second. The absolute velocity of the hydrogen molecules being now known at the temperature of melting ice, we can readily calculate
the velocity for any other temperature. For if the temperatures are estimated on the absolute scale, we have, as has been shown, T: T' = $\frac{n}{2}$V': $\frac{n}{2}$V, and hence V: V' = $\sqrt{T}$: $\sqrt{T'}$. For example, the velocity of the hydrogen molecules at the temperature of boiling water would be found by the proportion 1,843: V = $\sqrt{273}$: $\sqrt{373}$. Knowing now the velocity of the hydrogen molecules at any temperature, we can find the velocity of every other molecule whose molecular weight is known. Since for any given temperature $\frac{n}{2}$V = $\frac{n}{2}$V', we have V: V' = $\sqrt{m}$: $\sqrt{m}$. For the oxygen molecules which weigh 32 microcriths we have at the temperature of melting ice 1,843: V = $\sqrt{32}$: $\sqrt{2}$, and V = $\sqrt{461}$ metres a second. The velocity of the molecules of the heavier gases is still less, but in all cases it is very great as compared with that obtained with projectiles.

The weight and velocity of the molecules of different gases are known with great precision, because the data from which they have been calculated are very well determined. But the molecular relations we have next to consider cannot be ascertained with the same accuracy, and must be regarded as only rough approximations. Moreover, the methods by which they have been calculated cannot be described in a few words, and we can therefore only state here the general results. As we have shown, the molecules of a gas are flying about in all directions with great velocity; those of the air, for example, about 17 miles a minute. Could we by any means turn into one direction the actual motion in the molecules of what we call still air, this air would at once become a wind blowing 17 miles a minute, and exerting a destructive power compared with which that of the most violent tornado is feeble. We are unconscious of the molecular storm which is constantly beating around us only because it beats equally in all directions at once. Obvi­ously, however, an immense number of small masses of matter cannot be flying in every possible direction without constantly striking each other, and every time two molecules come into collision the paths of both are changed, and frequently reversed; so that although they move with such great velocity they make very slow progress. When a jar of ammonia gas, for example, is opened in a lecture room, a sensible time elapses before its pungent odor is perceived even at a distance of a few feet, and a long time passes before it reaches the distant end of the hall. Nevertheless, the molecules of ammonia at the ordinary temperature move over 20 miles a minute, and would flash over the hall were they not jostled about by the molecules of air. Still, although the process is a slow one, the gas does diffuse itself through the air, and we can easily devise experiments to test the rate of progress. The phenomena of which our illustration is a single example are among the most instructive effects of molecular motion, and under the same diffusion of gases they have long been studied.

It was discovered by the late Dr. Graham that two gases diffuse through each other at rates which are inversely proportional to the square roots of their densities, and this empirical law strongly confirms the molecular theory; for, as we have seen, the molecular velocities, which must determine the relative rates of diffusion, are also proportional to the square roots of the densities. More recently the diffusion of gases has been studied by Loschmidt of Vienna, who measured the absolute as well as the relative rates. He placed the two gases in similar portions of the same vertical tube, the lighter over the heavier, and after allowing them to diffuse during an observed time closed a sliding valve which divided the two portions, and then by chemical analysis determined the amount of gas which had passed in the two directions. According to our theory, the molecules of still air must also travel from place to place in the same halting manner as the gases; only we have not the means of noting their progress. Nevertheless, by communicating momentum or heat to one portion of a mass of air, under such conditions as to avoid the effect of currents, and observing the rates at which the momentum or heat spread by means of phenomena depending on these effects, we obtain data by which we can estimate approximately the travelling power of the molecules. Such phenomena depend on modes of diffusion, and Maxwell distinguishes between what he terms the diffusion of mass, the diffusion of momentum, and the diffusion of energy. Taking then into consideration the obvious principle that the greater the velocity of the molecules and the longer their path between successive collisions the faster they must travel, and remembering that we know the velocity of their actual motion, it can readily be seen that experiments on the three kinds of diffusion would give us the means of calculating what Clausius calls the mean path of a molecule, that is, the average distance travelled by a molecule between one collision and another; and further, that from the velocity and mean path we can estimate the number of collisions in a second. Of course the mean path varies for different molecules and under different conditions. That these paths should be very short we should expect, but our calculations surprise us by showing that they are of the same order of magnitude as the waves of light, and that the number of collisions in a second is to be numbered by thousands of millions. No wonder that although the molecules move so swiftly, they make so little progress.

As has already been said, the phenomena attending the condensation of a gas to a liquid have the appearance of the crowding together of hard masses, and suggest the conception that in the liquid state the molecules are as near together as when they come into collision in the state of gas. If this conception is accurate, the specific gravity of a liquid is the specific gravity of its molecules, and the diameter of a molecule is the distance between
the centres of two adjacent masses in the liquid state. It is generally assumed that the perfect elasticity of the molecules results from an elastic atmosphere, perhaps the ether, which surrounds them, and in a gas we distinguish between what we call the free path of the molecule and that portion of its motion during which the path is changed by collision; and the principal difference between a gas and a liquid seems to be, that while in a gas the molecules are almost all the time on the wing, in a liquid they are always in a state of close encounter with each other, and have hardly any free path. When therefore we define the diameter of a molecule as the distance between the centres of two adjacent molecules in the liquid state, we of course include the molecular atmosphere, or at least so much of it as produces an appreciable effect in the collision. If then we thus define the diameter of a molecule, it is evident that we can determine the relative diameters of molecules of different substances by comparing their densities in the airiform and liquid states. For the densities of the gases give us the relative weights of these molecules, and the densities of the liquids the weights of the unit volume of the liquids. Hence, by dividing the latter by the former, we learn the relative number of molecules in these equal volumes, and from this we at once deduce the relative volumes of the molecules and their relative diameters. Moreover, as these results agree very remarkably with those obtained by other means, we feel great confidence in the assumption on which they are based; and if our knowledge in regard to them is not precise, it is at least approximate. — We next come to a class of molecular data of which our knowledge is not only not precise, but not even definite, and whose assigned values can only be regarded as probable conjectures. Loschmidt has deduced from the principles of molecular mechanics the following theorem: "As the volume of a gas is to the combined volume of all the molecules contained in it, so is the mean path of a molecule to one eighth of its diameter." Since we know at least approximately the other three quantities, we ought to be able by this proportion to calculate the absolute molecular diameters. Accordingly, Maxwell has calculated from Loschmidt's data that "the size of the molecules of hydrogen is such that two million of them in a row would occupy a millimetre, and a million million million of them would weigh between four and five grammes;" and further, that "in a cubic centimetre of any gas at standard pressure and temperature there are about 19 million million molecules." Striking as these results are, they depend on so many uncertain elements that they must be accepted with caution. Still it should be added that from several wholly independent data, such as the lengths of luminous waves, the thickness of soap bubbles, and the electric properties of metals, Sir William Thomson has deduced values of the molecular magnitudes which are consistent with the numbers just given, and has proved that these magnitudes must fall within certain limits, which, though too wide to secure entire confidence in his methods, at least fix the order of the magnitudes.—In preparing this article we have been greatly indebted to the lecture on molecules delivered before the British association at Bradford in September, 1873, by Prof. Maxwell, and to sum up what we have said of the physical relations of molecules we reproduce from this lecture the table of molecular magnitudes, in which the values are classed according to the completeness of our knowledge in regard to them:

"These considerations will show how definite the idea of the molecule has become in the mind of the physicist. It is no longer a metaphysical abstraction, but a reality about which he reasons as confidently and as successfully as he does about the planets. He no longer connects with this term the ideas of infinite hardness, absolute rigidity, and other incredible assumptions which have brought the idea of a limited divisibility into disrepute. His molecules are definite masses of matter, exceedingly small but still not immeasurable; and they are the points of application to which he traces the action of the forces with which he has to deal. These molecules are to the physicist real magnitudes, which are no further removed from our ordinary experience on the one side than are the magnitudes of astronomy on the other. The old metaphysical question in regard to the infinite divisibility of matter, which was such a subject of controversy in the last century, has nothing to do with the present conception. Were we small enough to be able to grasp the molecules, we might be able to split them, and so were we large enough we might be able to crack the earth; but we have made sufficient advance since the days of the old controversy to know that questions of this sort, in the present state of knowledge, are both irrelevant and absurd. The geologist
tears the earth to pieces, and so does the chemist deal with the molecules; but to the astronomer the earth is a unit, and so is the molecule to the physicist. The word molecule, which means simply a small mass of matter, expresses our modern conception far better than the old word atom, which is derived from the Greek α πριντικό στην, and means therefore indivisible. In the paper just referred to, Sir W. Thomson used the word atom in the sense of molecule, and this confusion of the two terms is still common. We shall give to the word atom an utterly different signification, which we must be careful not to confound with that of molecule. In our modern chemistry the two terms stand for wholly different ideas, and, as we shall see, the atom is the unit of the chemist in the same sense that the molecule is the unit of the physicist. (The writer of this article, in "The New Chemistry," page 83, New York, 1874.)—The chemist studies the molecular theory from a point of view quite different from that of the physicist. To the physicist the molecules are the points of application of those forces which determine or modify the physical condition of bodies, and he defines molecules as the small particles of matter which under the influence of these forces act as unics. To the chemist, on the other hand, the molecules determine those differences which distinguish substances. Sugar, for example, has the qualities which we associate with that name, because it is an aggregate of molecules which have those qualities. Divide up a lump of sugar as small as you please: the smallest mass that you can recognize still has the qualities of sugar; and so it must be if you continue the division down to the molecules; and so is it with every substance. It is the molecules in which the qualities inhere. Hence the chemist's definition of a molecule: The smallest particles of a substance in which its qualities inhere. By no physical process, that is, by no process which leaves the qualities of a substance essentially unchanged, is subdivision carried beyond the molecules. The molecules can however be divided, but by the division you destroy the substance; new substances result, and you have what is called a chemical process. The distinguishing feature of a chemical change is simply this: From one or more substances one or more new substances are produced, and according to the molecular theory these changes depend on the reciprocal action of different kinds of molecules on each other. The molecules become subdivided, and new molecules are formed by a new grouping of the fragments. And here chemistry comes in to substantiate the molecular theory with most important evidence. If in a chemical change the reaction takes place between molecules, then we should expect that the weights of the substances involved in the process would bear some simple relation to the weights of their molecules, as determined by physical methods. Now this is exactly what we find to be true. It is the great law of chemistry that in every chemical process definite proportions are preserved between the weights both of the factors and of the products of the change; and wherever observation is possible it has been found that these weights bear a simple relation to the specific gravities of the substances in the state of gas, which, as will be remembered, are the measures of the molecular weights of these substances. A few examples will illustrate this point. When hydrochloric acid is combined with ammonia to form ammonium chloride (sal ammoniac), 36.5 parts by weight of the former unite with 17 parts of the latter. Now the specific gravities of these two gases with reference to hydrogen are by observation 18.93 and 8.53 respectively, and the molecular weights 36.5 and 17 microcriths, very nearly. When water is decomposed, 9 parts by weight of water yield 8 parts of oxygen gas and 1 part of hydrogen. The specific gravities of the several substances in the state of gas are (by observation) 8.98, 15.95, and 1, and the weights of the molecules therefore 18, 32, and 2 microcriths, very nearly. Examples like these might be multiplied indefinitely. The relation is very simple. The chemical proportions are always very nearly either as the molecular weights, deduced from the gas densities, or as some simple whole multiples of these weights; a fact which wonderfully confirms the molecular theory. But it is much be asked, why is not the relation just described absolute? First, because a certain amount of error of observation is inherent in all measurement, and the determinations of gas densities are peculiarly exposed to errors of this kind; and secondly, and chiefly, because the vapors, on which we mostly experiment, are not in the condition of perfect gases. They do not perfectly obey the law of Mariotte, and, as the molecular theory shows, it is only when they exactly obey this law that they contain the same number of molecules in the unit volume, and that their densities are the measures of their molecular weights. In the case of a few perfect gases the agreement between the two classes of observations is very close; but with most vapors, especially when near the point of condensation to liquids, we can only expect to find an approximation. It is evident moreover that the definite proportions of chemistry, which can be weighed with the greatest accuracy, are a far more exact measure of the molecular weights than the gas densities. Of course we cannot tell from these proportions alone whether they are the ratios between the weights of equal or of multiple numbers of molecules; but here the gas densities come to our aid, and fix approximately the values of the molecular weights, which we need only correct by the chemical evidence. When, as is most frequently the case, the substances with which we are dealing are incapable of existing in the state of gas, we
are obliged to depend wholly on the combining proportions for fixing their molecular weights; but although in such cases we have various chemical means of controlling our results, we are frequently in danger of assigning multiple values.—Chemistry has shown that all matter is composed of one or more of 64 substances, which we call elementary substances or chemical elements, because as yet they have not been decomposed; and by the processes of chemical analysis we are able to determine with great accuracy the relative proportions of each element which a compound may contain. Moreover, as the masses are aggregates of perfectly similar molecules, it is evident that in analyzing a substance we analyze also its molecules; and that when we learn, for example, that water, in every hundred parts, contains 88-89 parts of oxygen and 11-11 parts of hydrogen, we know that every molecule of water must consist of the same elements in the same proportions. The following tables contain lists of volatile compounds of four elementary substances. Opposite to the name of each substance is, first, the weight of its molecule in microcriths, and secondly, the amount in each molecule of the elementary substance common to the list. The molecular weights are deduced primarily from the gas or vapor densities, but are corrected by the known combining proportions of the compounds. The amount of the elementary substance which each molecule contains is calculated from the results of chemical analysis.

An inspection of these tables will reveal one of the most remarkable facts in the whole range of physical science. The molecules of the compounds of any element always contain quantities of that element, which are simple whole multiples of a definite mass; and this mass, which is the smallest quantity of an element found in the molecules of any of its compounds, is what we call the atom of that element. Thus the atoms of the four elements oxygen, chlorine, carbon, and hydrogen weigh respectively 16, 35.5, 12, and 1 microcriths respectively. It will be noticed that this definition does not necessarily imply that the atoms are isolated masses like the molecules. When water is decomposed, two substances, which we call oxygen and hydrogen, are evolved from the aqueous mass; and from each molecule of water there must be evolved by the chemical processes the quantities of these elementary substances which we call one atom of oxygen and two atoms of hydrogen. Whether now these masses preexisted in the molecule, or are formed from it by some unknown and unconceived transformation of its substance, is a question about which we can only speculate. Nevertheless these atoms are definite and invariable quantities whether preexisting as isolated masses in the molecules or not; and the only theory which has been advanced that gives an intelligible explanation of the facts
assumes that the atoms are not only invariable quantities, but definite bodies, and that the molecules are combinations of atoms, except, of course, in those cases where the molecules consist of a single atom. The atom is the unit of the chemist in the same sense that the molecule is the unit of the physicist; and as the molecules are the limits which the subdivision of matter reaches in any physical process, so what we now regard as atoms are the limits of the subdivision in any known chemical process. The word atom, by which we designate these units of chemistry and which we have inherited from the past, is in some respects an unfortunate term, because its etymology suggests conceptions which are no longer associated with the small masses it designates. Although our chemical atoms have never as yet been divided, we do not regard them as necessarily indivisible. Several atoms of oxygen for example, weighing 16 microcriths, is simply the smallest quantity of this elementary substance known to exist in a molecule of any of its compounds. It is by no means impossible that a compound of oxygen may be discovered whose molecule contains only 8 microcriths of the element; or in other words, that what we now call an oxygen atom may be divided, just as it is possible that the elementary substance may be decomposed; for the chemical atom, like the chemical element, is such only provisionally. The distinction between atom and molecule is preserved in chemistry by the system of chemical symbols. The Latin initials which are used as the symbols of the chemical elements represent in every case one atom of the elementary substance, and the groups of these letters which are used as the symbols of chemical compounds stand in each case for one molecule of the compound. Thus O stands for one atom or 16 microcriths of oxygen, C for one atom or 12 microcriths of carbon, H for one atom or one microcrith of hydrogen; H₂O for one molecule of water, C₁₂H₂₀ for one molecule of alcohol, C₆H₅O₂ for one molecule of acetic acid. The figures below the symbol indicate the number of atoms of the corresponding element in the molecule, and the weight of the molecule is obviously the sum of the weights of the atoms which the symbols represent. For example, the weights of the molecules of water, alcohol, and acetic acid are 18, 46, and 60 respectively. Several molecules of a compound may be indicated by placing figures before the group of symbols like an algebraic coefficient; thus 3H₂O stands for three molecules of water, and 4C₆H₅O₂ for four molecules of acetic acid. In order to determine the symbol of a molecule, we must know in the first place the molecular weight, and in the second place the percentage of composition. The molecular weight, as we have seen, is found approximately from the gas or vapor density, and corrected by the combining proportions of the substance. The percentage composition is determined by a quantitative chemical analysis. As an example, suppose we wished to determine the symbol of butyric acid. The specific gravity of the vapor of this volatile compound was determined by Calhoun and found to be 44.3, hydrogen gas being unity. Hence the molecular weight would be 88.6 microcriths, but the combining proportions of the acid deduced from analyses of its salts prove that the more accurate value is 88 m. c. An analysis of the acid published by Grünzweig gives the following percentage composition, and from this we easily calculate the amount of each element in 88 m. c. or one molecule:

Evidently in the molecule there are 4 atoms of carbon, 8 atoms of hydrogen, and 2 atoms of oxygen, and the symbol is therefore C₆H₅O₂. Thus we can fix the symbols of all volatile bodies. If the substance is non-volatile, we rely primarily on the combining proportion to fix the molecular weight and, as has been said, there is frequently danger of assigning multiple values. But as a general rule the chemical relations of the substance enable us to determine which of the possible multiples should be taken; and if these leave us in doubt, we adopt provisionally as the symbol of the molecule that multiple which has the smallest number of whole atoms, and wait for the progress of science to correct any error. But even after fixing a number and kind of atoms to which they consist, chemistry has gone forward still further in developing the molecular theory, and has discovered a large and important class of phenomena, which it refers to differences of arrangement in the grouping of the atoms of the molecules. Thus, there is a substance called acetic ether which has the same molecular weight and the same percentage of composition as butyric acid. Its molecules therefore contain the same number of the same kind of atoms as the ether. Yet the qualities of the two substances are utterly different, the acid having the disgusting smell of rancid butter and the ether the pleasant odor of apples, and chemistry attempts to explain this difference by showing that the atoms are arranged differently in the two classes of molecules, as the following diagrams indicate:

Butyric acid.

Acetie ether.
Substances so related are said to be isomeric, and these structural formulas, as they are called, so far from being vagaries of the imagination, are sober deductions from experimental evidence. It is impossible however, in a brief article, to render this evidence intelligible. The investigation of molecular structure is at present the chief aim of chemistry, and to works on this subject the reader is referred for further information.

MOLENBEER-ST-JEAN, a town of Belgium, adjoining Brussels and forming one of its suburbs; pop. in 1817, 80,974 (in 1846, 12,060). It has a celebrated geographical institution and a museum of natural science belonging to Messrs. Van der Maalen.

MOLESCHOTT, Jacob, a German physiologist, born in Bois-le-Duc, Holland, Aug. 9, 1822. He took his degree at Heidelberg in 1845, practised medicine at Utrecht till 1847, and afterward lectured at the university of Heidelberg till 1854, when, having been accused of pantheism and of propounding precepts dangerous to religion and morals, he resigned. He accepted in 1856 a professorship in Zürich, and in 1861 the chair of physiology in Turin. His doctrine has been popularly described as based upon the German saying that "Der Mensch ist was er ist (man is what he eats), or upon his own formula, Ohne Phosphorus kein Gedanke (no thought without phosphorus); and though he does not deny the existence of a spiritual life, he connects the origin of all species of animals with physical laws alone. His influence has greatly promoted the study of physiology and anthropology, and he has given especial attention to food and diet, the liver, the blood, milk, the origin of bile, and the structure of the muscles. His principal works are: "Lehre der Nahrungsmittel" (Erlangen, 1850; 2d ed., 1858; English translation, "The Chemistry of Food and Diet," by Dr. E. Bonner, London, 1856); "Physiologie der Nahrungsmittel" (Darmstadt, 1850; 2d ed., Giessen, 1859); "Der Kreislauf des Lebens" (Mentz, 1852; 4th ed., 1883); "Georg Forster" (Frankfort, 1854; 2d ed., 1892); "Ursache und Wirkung in der Lehre vom Leben" (Giessen, 1887); and "Von der Selbstbestimmung im Leben der Menschheit" (1871).

MOLENSWORTH, William Nassau, an English author, born at Millbrook, near Southampton, Nov. 8, 1816. He graduated at Cambridge, and in 1841 became incumbent of a church at Manchester, and in 1844 vicar at Rochdale. His works include "A History of the Reform Bill of 1832" (London, 1864); "A New System of Moral Philosophy," and a "Prize Essay on Education" (1867); and "The History of England, from the Year 1830" (3 vols., London, 1871-74).

MOLETTA (anc. Respa), a fortified seatport town of S. Italy, on the Adriatic in the province and 16 m. W. N. W. of the city of Bari; pop. in 1871, 26,829. It is the see of a bishop, and has a cathedral, several other churches, a college, a museum, and a castle. Linen and saltpetre are manufactured, and small coasting vessels are built. In the vicinity are numerous oval caverns arranged in tiers, one of which, called the Pulo di Molfetta, is upward of 1,000 ft. in circumference and 100 ft. deep. Nitre abounds in all the caverns, and is largely extracted.

MOLIÈRE, the assumed name of Jean Baptiste Poquelin, a French dramatist, born in Paris, Jan. 15, 1622, died there, Feb. 17, 1673. He was both the son and grandson of esclats de chambre tapissiers to the king, and was himself destined for this trade. His grandfather occasionally took him to the hôtel de Bourgogne, where Belleroze then acted in genteel comedy, and Gauthier-Garguille and Turlupin in farce. Obtaining permission to engage in study, he went in 1647 to the Jesuit college of Clermont in Paris, where he remained five years. He enjoyed the private lessons of Gassendi, and was associated with the prince of Conti, afterward his patron and friend, Bernier, Hesnault, and Chapelle. He studied law at Orleans, and was admitted an advocate in 1654; but his taste for the stage caused his return to Paris. The attractions of the actress Madeleine Béjart were reported also to have influenced his judgment. The example of Richelieu had created a general interest in the drama, and Poquelin became the head of a troupe of amateur comedians, which was soon transformed into a regular professional travelling company, known as l'illumé théâtre. He then assumed the name of Molière. Little is known of his life in the provinces from 1648 to 1653, when he returned to Paris. He composed numerous imitations of Italian farces, some of which were the first sketches of his future comedies. At Bordeaux he was welcomed by the duke d'Épernon; at Lyons he obtained the accession of Mme. Duparc and Mme. de Brie to his company, which already included the brothers and sister Béjart; and at Pézenas he was accustomed to sit every Saturday in a barber's shop to study the faces and conversation of the visitors. His first regular comedy was L'Étourdi, represented at Lyons in 1653, which by its success induced the principal members of a rival company to join his troupe. After visiting the chief cities of the south, he entered the capital under the protection of Monsieur, duke of Orleans. His performance of his own Docteur amoureux before the court and the comedians of the hôtel de Bourgogne was so satisfactory that his company was permitted to establish itself in Paris under the name of the troupe de Monsieur. It became the troupe du roi in 1665, and subsequently was united with that of the hôtel de Bourgogne to form the Théâtre Français. During the last 15 years of his life he produced more than 30 plays, half of which are masterpieces. He opened a new one in 1659 by his Précieuses ridicules, abandoning the traditions of the Italian and Spanish stage, and assailing the affectations encouraged in literature and soci-
ety by coteries that ridiculously adopted the tone of the hôtel de Rambouillet. The play had a run of four months. At brief intervals followed Sganarelle, ou le coq imaginaire (1660), a somewhat scandalous farce; Don Gac-
cie de Navarre (1661), which failed; L'École des maris (1661), in which the leading idea is borrowed from the Adolphi of Terence, and
the character of Sganarelle attains its fullest development; and Les fâcheux (1661), the first and one of the finest examples of a comé-
die à tiroirs, designed to be acted in the intervals of a ballet. In 1662 he married Ar-
mande Béjart (a sister of the actress in his
company), whom the slanders of the time charged with being a daughter of his former
mistress. This has been completely disproved
by legal documents brought to light in 1821.
His three next plays, L'École des femmes (1662),
La critique de l'École des femmes (1663), and
L'Impromptu de Versailles (1663), increased the
animosity against him. The first and sec-
ond aroused the suspicions of the religious
party, and the third drew upon him the un-
scrupulous assaults of the rival troupe at the
hôtel de Bourgogne. In 1664, at the brilliant
fêtes de Versailles, Molière and his company
contributed to the gayeties on four of the sev-
en days. He presented La princesse d'Élide,
a romantic and gorgeous play, and the first
three acts of Tartuffe, a satire on hypocrites,
the success of which when completed was
greatly increased by the king's forbidding its
representation in Paris. He treated a kin-
dred topic in the comedy of Le festin de
pierre (1665), which portrays the multiple char-
acter of Don Juan. This was preceded by Le
marriage forçé directed against the theologians
of the Sorbonne, and followed by L'Amour
médicin, which began the war with the med-
ical faculty continued by Molière through
life. Within the next three years followed Le
misanthrope, which Frenchmen pronounce his
chef d'œuvre, partly from its faultlessness of
style, and partly from its portraiture of Al-
ceste, who runs counter to the conventional
hypocrisies of social intercourse, and of Céli-
mène the coquette and Arsinoé the prude; Le
ménage malgré lui, a rollicking farce, which had
the greatest success; Amphitryon, an imita-
tion of Plautus; L'Atrée, exhibiting in the
character of Harpagon the comical relations
of avarice; and Georges Dandin, designed to
expose the mischief resulting from ill-assorted
marriages. His Tartuffe, the greatest effort of
his genius, was also once acted with signal
applause at the Palais Royal, but its second
representation was immediately forbidden, and
within a week the archbishop had threatened
excommunication against any who should act,
read, or listen to it. In the period between
the performance of Tartuffe in Paris and the
death of Molière, the less important pieces
which he successively produced were the farce
of Monsieur de Pourveuvoye; the Amants
magnifiqùes, in which astrology is satirized;
Pope Clement VIII., and a special committee of cardinals was appointed by him in 1597 to examine into the matter. After years of discussion they reported, and in 1609 Paul V. decided that both the Thomist and the Molinist system could be safely taught. The Jesuit Suarez modified Molina's system in a sense opposed to free will, and inconsistent with the latter's doctrine. In our own times Molina's doctrine has been openly taught in Rome, and is in favor with many Dominicans. His famous book was first published with the title Libri Arbitrii cum Gratia Domini, Divinae Prae- scientiae, Providentiae, Prædestinatione et Repro- batione Concordia (4to, Lisbon, 1588). An appendix containing a defence of his system appeared in 1589; and editions of the entire work were printed at Lyons in 1598, at Venice in 1594, and at Antwerp in 1595.

**MOLINE**
A city of Rock Island co., Illinois, on the E. bank of the Mississippi river, 3 m. above Rock Island, and at the intersection of the Chicago, Rock Island, and Pacific, the Rockford, Rock Island, and St. Louis, and the Western Union railroads, 179 m. W. by S. of Chicago; pop. in 1870, 4,166. The river is here divided by an island 3 m. long, and from 16 m. above to 8 m. below the city are the Upper Rapids. By means of a dam immense water power is obtained, and employed by various manufactories, constantly increasing in number and importance. The principal establishments are two extensive plough factories, a paper mill, a woollen factory, tub and bucket factory, wagon factories, founderies, machine shops, flouring mills, &c. The surrounding country contains extensive coal fields. The city has graded schools, including a high school, a free public library, two national banks, a savings bank, a weekly newspaper, and eight churches. It was first settled in 1852.

**MOLINISTs**
See MONTA.

**MOLINOS, Miguel de,** a Spanish mystic, born in the diocese of Saragossa in 1637, died in Rome, Dec. 29, 1696. He studied at Pamplona and Coimbra, was ordained priest, and in 1669 settled at Rome. In 1675 he published in Spanish a work entitled "The Spiritual Guide," which passed in a few years through 20 editions. Its theories of a religious life, which obtained the name of "quietism," taught that spiritual perfection consisted in the perfect repossession of all the faculties of the soul in God, and indifference to all the actions of the body. For those who attained this "fixed" or "continuous" state, there was no sin, and no occasion for anxiety. The "Spiritual Guide" was condemned by Pope Innocent XI. in 1687, and the author, after making a public recantation, was committed to prison, where he passed the rest of his life. When his papers were seized, 20,000 letters were found from persons desiring his counsel in spiritual matters. His doctrine was never taught, in a form very much modified, by Mme. Guyon, and were reechoed faintly in Fénelon's "Maxims of the Saints."

**MOLLIQUE, Wilhelm Bernhard,** a German violinist and composer, born in Nuremberg, Oct. 7, 1802, died in Cannstadt, May 10, 1869. His father, who was chapel-master, gave him his first lessons and taught him the use of several instruments. He showed a strong preference for the violin, and at the age of 14 was sent to Munich and placed under the instruction of Rovelli, whom he succeeded in 1820 as first violinist of the court. In 1822 he made a concert tour through Germany, which did much to increase his reputation. He was concert director at Stuttgart from 1826 to 1849, when he went to London, and in 1861 was made professor of composition at the royal academy of music. His works are mostly for the violin, and are held in high esteem. He has also written a symphony, a mass for voices and orchestra, and "Abraham," an oratorio.

**MOLISE.** See CAMPOBASSO.

**MOLLER, Georg,** a German architect, born at Diepholz, Hanover, Jan. 21, 1784, died March 13, 1852. He studied in Carlsruhe and in Italy, and was architect of the grand ducal court at Darmstadt. He published in 1818 a facsimile of the original design of the cathedral of Cologne, which he had discovered in Darmstadt, and which, with an additional design found subsequently, is followed in the completion of the two towers of that edifice. His works include many public and private buildings in Darmstadt and other places, and the ducale palace in Wiesbaden. His principal publications are: Denkmäler deutscher Kunst (3 vols., Darmstadt, 1815-45); Denkmäler deutscher Baukunst (1821); and Beiträge zur Constructionslehre (6 numbers, 1855-42).

**MÖLLHAUSEN, Balduin,** a German traveller, born in Bonn, Jan. 27, 1835. He came to the United States, in 1851 visited the Rocky mountains with Duke Paul of Württemberg, returned to England in 1852, and in 1853 went as photographer and draughtsman to Lieut. Whipple's expedition to the Pacific. In 1857-8 he was engaged in Colorado, with Lieut. Ives. Besides several novels, he has published Tagebuch einer Reise vom Mississippi nach der Südsee (Leipsic, 1858; English translation by Mrs. Sinnett, 2 vols., London, 1858; 2d ed., entitled Wanderungen durch die Prairien und Wästen des westlichen Nordamerika, 1860); Reisen in die Felsengebirge Nordamerikas bis zum Hochplateau von Neumeziko (2 vols., 1861); Nord und Südt, Erzählungen und Schilderungen aus dem westlichen Nordamerika (2 vols., Jena, 1867).

**MOLLUSCA,** a branch of the invertebrate animal kingdom, so named from the general softness of the body; some of its members were first defined by Aristotle under the name of malac-ka (soft animals), of which the Latin mollusca and English mollusk are rude equivalents. Cuvier, between 1792 and 1817, determined the characters and boundaries of this branch by investigating its anatomical structure; before his time the study of the shells with which
most mollusks are provided, or conchology, had occupied almost the exclusive attention of classifiers. (See Conchology, and Malacology.) The microscopic anatomy and embryology of mollusks led to the separation of cirripeds, and to their being placed among articulates in the class of crustaceans; for the same reason the *bryozoa* were taken from polyps and placed among acephalous mollusks, and since, with the brachiopods and ascidians, among articulate. The mollusca (heterogangiata of Owen) include such animals as have one or more nervous ganglia below the entrance to the alimentary canal, from which radiate cords which form a circular cord of the oesophagus and supply the other organs of the body; in the higher forms other ganglia are added above the oesophagus and unsymmetrically in different parts of the body. From the sac which invests the body they have been called succata by Prof. Hyatt. In addition to the writers alluded to under Malacology, may be mentioned Poli, Rathke, Savigny, Chamisso, Pfeiffer, Deshayes, Forbes and Hanley, Loven, Quatrefages, Kiener, Chenu, Chemnitz, Rang, Alder and Hancock, Ferussac, D'Orbigny, Philippi, Sowerby, Johnston, Martini, Huxley, Eschricht, and Delle Chiaje; and in the United States, Say, Conrad, Lea, Couthon, Binney, Adams, Jay, Haldeman, Gould, Morse, and Hyatt.—In mollusks the body is covered by a soft moist skin, in or on which a shell is usually secreted; many have no head distinct from the rest of the body; the organs of sense are comparatively slightly developed, and the movements slow. Respiration is effected usually by gills; a heart is generally present, receiving the blood from the gills, and distributing it by arterial tubes; the capillaries are wanting, and the veins are replaced by sinuses; the blood is commonly whitish or whitish blue. The developmental energies seem to have been expanded chiefly in the perfection of those organs concerned in the preservation of the individual and the species; some mollusks are hermaphrodite and require mutual impregnation, and in others the sexes are distinct; most are oviparous; the eggs, often connected in bunches or adhering to each other by a gelatinous substance, have a thin outer shell or chorion, sometimes of a horny consistency. The terrestrial species are few compared with those of fresh, and especially of salt water.—In the lowest class of *acephala* or headless mollusks, in the old classifications, we had the orders of *bryozoa*, *tunicata*, *brachiopoda*, and *lamellibranchiata*. As stated under Brachiopoda and Bryoza, Prof. E. S. Morse regards the first of these orders as articulates, coming near the tubicolous worms; and there are good reasons, as there stated, for including also the *bryozoa* or *polyzoa* and the ascidians or tunicates among the articulates with molluscan affinities, which have been separated by recent authors under the division molluscoidea. (See Molluscoidea.) The acephalous mollusks, the lowest of the branch, the *lamellibranchiata*, are characterized by a right and left shell, enclosing a depressed body, covered on both sides by a layer of the mantle; the branchiae are at the sides of the body, mostly lamellar (whence their name) and placed under each lobe of the mantle, but sometimes pectinated; they are generally two on each side, and sometimes the triangular interval between them on the dorsal surface is used as a temporary deposit for the eggs. Most have four lamelliform tentacles, in pairs on the sides of the mouth; the shells are opened by an elastic ligament at the back, and are closed by one or two internal muscles, in the former case being called mononyaria, and in the second *dimyaria*. The heart is arterial, consisting of a ventricle and usually of two auricles, the former being generally traversed by the end of the intestine. They inhabit both salt and fresh water, and usually live with the back uppermost, resting on the ventral edge of the shell; the sexes are in most cases distinct, and may often be recognized by the shape of the shell; some are hermaphrodite, and the young are sometimes considerably different from the adults; they are ovoviviparous. As a rule there are three central nerve masses, each consisting of two lateral ganglia, of which the first two are always distinct from each other. The valves of the shell are in most of the same shape and size, but in some of the fixed species the lower is the deeper; in the oyster, the lower and larger is the left valve; in some the valves close tightly, in others they are open at one or both ends for the passage of the foot and other organs. Along a part or the whole of the margin of the mantle are conical cirri or organs of touch, and also tactile gill-like laminae around the mouth; and this class is frequently sensible of light. Some have a firm and muscular prolongation from the abdomen called the "foot," possessing great contractility, by means of which they move about at the bottom of the water; at the base of the foot in others is a bundle of filaments, called the byssus, secreted by a glandular tissue, and occasionally united into a common mass; a familiar example of this is seen in the common mussel (*mytilus borealis*, Lamarck), which attaches itself by its silken threads very firmly to rocks, shells, and seaweeds; a few, unpredicated with a byssus, grow fast by one of the shells to submarine objects. Many of this class are entirely fossil, and of some genera the extinct species are more numerous than those now living, the latter being in this case usually found in the Indian and South Pacific oceans. Among the mononyarians may be mentioned the common oyster and the comb or scallop shell (*pecten*); among the dimyarians, the pearl oyster (*mlesagra*), hammer shell (malleus), wing shell (*pina*), mussel (*mytilus*), ark shell (*arca*), fresh-water clam and mussel (*unio* and *anodonta*), cockle (*cardium*), the great clam or bêche-à-terre (used in Roman Catholic churches to contain
holy water, sometimes 2 ft. wide, genus tri-
dactyla, the largest of the class), the horse-foot
clam (hippopus), the edible quahog (venus
mercenaria, the shell from which the wampum
of the American Indians was made), the small
fresh-water cyclas, the common clam (mya are-
naria), the razor shell (solen), the pholas (pidd-
dock or stone-borer), the ship worm (teredo),
so destructive to timber in vessels and dock-
yards, the waterpot shells (aspergillum), and
the club shells (clairvagella). All bivalves are
very prolific; in those which, like the oyster,
are fixed, the sperm cells of the male are car-
ried by the currents of the water to the cavity
of the mantle of the female.—The remaining
three fourths of mollusks are called eoceneha,
from having a distinct head, commonly with
eyes and tentacles, and a mouth with a com-
plex masticatory apparatus; they have been
divided into the classes of cephalopora (head
bearers) and ephalopoda (with the head sur-
rounded by the foot). The cephalopora have
been subdivided, according to the modifications
of the locomotive organs, into the orders of
pteropoda, heteropoda, and gastroepoda. The
pteropoda are so called from two wing-like
muscular expansions from the sides of the an-
terior part of the body, used as swimming or-
gans, and not, according to Owen, homologous
with the foot of gastroepods; they are small,
marine, floating, hermaphroditic, and oviparous;
the form is very variable, some being globular,
others long and slender; the heart, as in the
whole class, is arterial; the urinary sac, within
the mantle and near the heart, communicates
with the respiratory cavity and with the pericar-
dial sinus, introducing water into the blood;
some are naked, others are provided with very
delicate shells of various forms; the eyes are
not well developed, but the acoustic sac exists
in all; the naked species have four tentacles,
the testaceous ones two. In the family the-
cosomata, the head is indistinct, and the shell
fragile; the best known genera of this family are
hyale and cleodora, found in the warmer
temperate and tropical seas; some of them
are beautiful objects, as they swim through
the water like butterflies in the air; one of the
largest and finest is the H. tridentata, three
fourths of an inch long, commonly known as
the "chariot of Venus." In the family gym-
nosomata, or naked pteropods, the head is dis-
tinct, and the fins are attached to the sides of
the neck; it includes the genera elio and pneu-
momdero; of the former, the C. borealis ex-
ists in such immense numbers in high northern
latitudes, that it forms a chief portion of the
food of the Greenland whale, and is hence
called "whale bait" by the fishermen; it is
hardly an inch long.—The order heteropoda
is characterized by a compressed fin-like foot
having a sectorial disk; the branches are
fringed or pinnate; the sexes are distinct. All
are marine, and usually are rapid swimmers
with the back downward and the foot upward;
the foot corresponds to the anterior portion of
this organ in gastroepods. They are some-
times called nucleobranchiates, and may be di-
vided into the families atlantida and firolida.
In the first family belongs the atlantia, with
a delicate shell large enough to protect the body,
found in great numbers in the midst of the
tropical and temperate oceans; in these the
foot supports the operculum. In the second
family is placed cartinaria, sometimes called
the "glassy sailor," which has an elongated
body, with a very small keeled shell at the pos-
terior part, the apex turned backward; on
the head are two long tentacles, and two ses-
sile eyes behind their base; the middle part of
the foot is reduced to a compressed fin-shaped
lobe, with a small sectorial disk, by which they
adhere to seaweeds, &c.; their motions are
rapid and graceful, and they inhabit the tem-
perate and tropical waters; a small species is
found in the Mediterranean; the shell of the C.
esteria, from the Indian ocean, is highly prized.
In the genus firola or tarcercoths there is no
shell, and the animal is almost transparent;
there are two eyes, and generally no tentacles,
but a slight fleshy proboscis; they swim or
float free in mid ocean in great numbers, and
also in the Mediterranean.—In the order gas-
teropoda there is a large muscular disk for
creeping developed from the ventral surface
of the body (hence the name), as in the com-
mon slugs and snails. They are usually un-
symmetrical, the visceral portion of the body
coiled spirally and protected by a univalve
shell, the organs of respiration being generally
atrophied; the shell is almost always closed
by a calcareous, horny, or albuminous oper-
culum. Most of them are marine, some in-
habit fresh water, and a few are terrestrial;
they have been divided according to the charac-
ters of the breathing apparatus. In some
(monacia) the male and female organs are
in the same individual, in others (dieseia) the
sexes are distinct; most are oviparous, but a
few (certain snails) are ovoviviparous. In
the water breathers the young are excluded
with an operculated shell, which in the naked
species is either shed or concealed by the mantle
and by means of eliillate fins on the sides of
the head they move far away from their inac-
tive parents, undergoing several metamorpho-
ses in the process of growth; the air breath-
ers pass through no such changes. They have
the power of repairing injuries and of repro-
ducing lost parts to a considerable degree.
Among the monocious gastroepods are the
following five divisions: I. Apneusta, having
no distinct respiratory organs, but in their
place an extensive aqueferous system, and no
shell in the adult; the body is soft and elonga-
ted, the integument eliillated; they are marine;
calliotopus and acteon are well known genera.
II. Nudibranchiata, with the branchiae exten-
ding freely from various parts of the body, as
in glaucus, doris (sea lemons), in which the
branchiae form a plume-like circle in the mid-
dle of the back, and colis (sea slugs), in which
they are papillose and arranged along the sides of the back. III. Inferobranchiata, like ptyg- 
latia, in which the branchiæ are at the lower part of the body. IV. Testibranchiata, in which the leaf-like branchiæ are covered by the mantle and a small shell; as in aplysia (sea hares), formerly dreaded on ac-
count of their strange form, and the violet fluid they eject when molested, in umbella, and in bulla (bubble shell). V. Pulmonata, in which a part of the mantle cavity forms a vac-
ular arm; most are terrestrial, and such as live in the water rise to the surface to breathe; a few are naked, but most are shell-
bearing, with or without an operculum; in the inoperculated, with a well developed shell, are helix (snails), euclinea (amber snail), vitrina, bu-
limus, pupa, achatina, and other land snails, the slugs (limax), land snails (aron), pond snails (limmen), &c.; in the operculated are cyclostoma, helicina, aculea, &c. In the concoid gastero-
pods belong the following four divisions: I. Tu-
bullibranchiata, in which the branchiæ are two, symmetrical, behind the heart, and enclosed with the other soft parts in a long shelly tube; as in dentatium (tooth shells). II. Cyclobran-
chiata, in which the branchiæ are a series of lamellæ, surrounding the body between the foot and mantle; as the limpets (patella) used as food and for bait, and the sea wood-lace (chiton), with multivalve shell pieces like the carapace of articulate. III. Dentibranchiata, in which the branchiæ are plumose or peci-
nate, and with the body protected by a widely opened inoperculated shell; as in the ear shells (halioïdes); the delicate violet shells (janthina), found abundantly in mid ocean, feeding upon the scalophan seelæ, and suspended by a raft of air vesicles, to the under surface of which the egg capsules are attached; and the fissuré-
lo, or key-hole limpets. IV. Pectinibranchiata, in which the two comb-like branchiæ are contained in a dorsal cavity of the mantle opening widely above the head; they have two feelers and two eyes, and a proboscis capable of elongation in a tube form; the females se-
crete an albuminous matter in which the eggs are enveloped, a familiar example being the yellow grape-like bunches of the whelk (buccin-
um). Here belong the bonnet limpet (calyp-
træa) and the slipper shell (crepidula); the top shells (turbo), and the pheasant shells (phasia-
nella); the river snails (paludina), the peri-
winkles (titorina), the turret shells (turritella), the ventletraps (scalaria), the cerithium, and nativa; cowries (cyprea), very handsome shells, and one species, C. moneta, used as money on the W. coast of Africa; marmorina, ovula, mitra (mitre shells); the tuns (dolium), harps (barga), whelks (buccinum); rock shells (ma-
rez), fig shells (pyrula), wing shells (strombus), the eraphs (terebullæ), and numerous others.

—the class of cephalopoda, the highest type of mollusks, is characterized by the locomotive and prehensile organs being attached to the head, whence they radiate in the form of mus-
cular arms and tentacles, and by an internal skeleton combined in some with an external shell, though the integument in most is uncal-
ified and flexible; the head is free and the body is covered by a muscular sac or mantle, with a transverse anterior aperture, from which projects the expiratory siphon or tube; the branchiæ are concealed, the sexes distinct, and the animals oviparous, aquatic, marine, predato-
ry and carnivorous, nocturnal, and social; the colors are changeable and brilliant; they emit an inky secretion when disturbed, which permits them to escape by the discoloration of the water; this is what the true India ink is made from. This class have a rudimentary internal skeleton; in the head of most is a car-
tiligious ring around the esophagus, the upper part covering the cerebral ganglion, and containing the organs of vision and hearing; there is often an additional cartilage to which the muscles of the arms are attached, and others on the back and sides. The mouth is in the middle between the arms, and has two jaws like the bill of a parrot, the lower the larger; the head is separated from the body by a con-
striction like a neck; there is a well marked tongue. The sexual organs are in the base of the visceral sac, and the spermatothoraces are very active; in some of the octopods, one of the arms is deciduous, and becomes a male or-
gan, described by Cuvier as hectocotylus and a parasite; the eggs are laid in heaps or bunches, attached to each other and to foreign bodies. The nervous system is largely developed. For respiration water is drawn in and expelled by the muscular action of the mantle and funnel, as the gills have no vibratile cilia; the water enters the branchial cavity at the anterior opening of the mantle, and is forced out through the funnel, propelling the animal backward. In the first order, the tetrabranchiata, the branchiæ are in two pairs, without branchial hearts, and the mantle is thin and not very muscular; the ink bag is absent; the arms are very numerous, hollow, and with retractile tentacles; eyes pedunculate; the head retra-
tile within a many-chambered siphunculated cell. Among existing mollusks this order con-
tains only the genus nautilus (see NAUTILUS); in past ages lived the ammonites, beculites, hamites, orthoceratites, turritelles, &c. In the second order, the diibranchiata, the branchiæ are two, each with a branchial heart; the funnel is an entire tube, and the mantle is muscu-
lar; an ink bag is present; there are eight non-
retractile arms, large and complicated, bearing sucking disks or acetabula, with usually two additional long arms; the eyes are sessile and in orbits; the shell is internal except in the female argonauts. In the decapod tribe, with eight arms and two tentacles, belong the genus spirula, the extinct belemnites, the cuttle fishes (sepia), and the squids. (See Squi.) In the octopod or eight-armed tribe there are no tenacles, the arms have sessile suckers, and the branchial chamber is divided by a longitu-
MOLLUSCOIDS

dinal partition; the arms are more robust, and are often united by a web at the base, constituting a powerful swimming organ. Among the naked octopods belong the so-called sea spiders. (See Octopods.) Eledone and trepostome are allied genera. The genus argonauta or paper nautilus is well known for the delicate and beautiful shell of the female. (See nautilus.) The shell is used only for protecting and hatching the eggs; the male has no shell, and impregnation is effected by a deci-

uous hectocotylus.—The local distribution of fauna and the distinctness of zoological regions are well illustrated by mollusks; while some are very limited in their range, others, like the cyprea, are extensively spread even across ocean barriers; some are cosmopolites, wandering wherever their food is found; helix cella-
ria, attaching itself to water casks, occurs in most seaports of the world, H. similis wherever the coffee plant grows, and H. vittinoides follows the taro or arum esculentum. As a general rule, according to Mr. Jeffreys, speci-
mens are larger toward the north than toward the south; colors are usually the brightest in the tropical seas, except in specimens from great depths. (For details on distribution, see "Mollusca and Shells of the United States Exploring Expedition," 1838-42, by A. A. Goodrich, M. D., Boston, 1852.) The distribution of mollusks in time extends from the lower Silurian to the present epoch; all the classes are represented in the earliest fossiliferous strata; some families, like the ammonites and belemnites, have passed away; others, like the nautilus, are verging toward extinction; some have continued with slight specific modifications from the Silurian to the present day. Lamellibranchiate have succeeded palliobranchiate bivalves; siphanate have succeeded asiphonate univalves; and the dibranchiate now vastly outnumber the tetrabranchiate. Whole strata of the earth's crust are made up principally of the shells of mollusks.—Mollusks supply an abundant, wholesome, and usually easily digestible article of food to nations civilized and savage, as well as to other animals; bivalves are considered the best, having the least muscular fibre. The ornamental purposes to which the pearl and cameo shells are put are well known; from the cuttle fish is obtained sepia and India ink; from the purpura and baccinum of the Mediterranean came the famous Tyrian dye of antiquity; from the filaments of the byssus of pinna are made tissues much esteemed on the shores of the Mediterranean. On the other hand, mollusks are sometimes injurious to man; slugs and snails do mischief in gardens; the teredo pierces ship timber, and the pholus bores into and weakens stone dikes. The number of species of mollusks probably exceeds 25,000, surpassed only by the number of articulate.

MOLLUSCOIDS, a division of the old branch of mollusca, first made by Milne-Edwards to include the bryozoa and ascidians or tunicates, to which have since been added the brachiopods; all of which are now regarded by Prof. E. S. Morse and others as articulate, having certain molluscan affinities, but coming nearest to the tubicolous worms. (See BRACHIOPODA, and BRYOZA.) In the lowest of these, the bryozoa, are comprised small pedunculated ani-

mals, the margin of whose body is provided with vibratile cilia, for producing the water currents necessary to respiration and to the obtaining of food; these cilia are sometimes supported on long tentacular prolongations; the digestive cavity is distinct from the walls of the body, and can be traced as a canal from mouth to vent, both opening within the ciliated circle, being reflected upward; they propagate by buds and by free swimming ciliated gem-

ules. They seem to have both males and females on the same stem, the cells containing animals with eggs being apparently more nu-

gerous than those with spermatozoan; the mus-

cular system is largely developed, and serves principally to retract the animal within its cell. They have been divided by Van der Hoeven into the families: 1, stebmatopoda, in which the tentacles are disposed in a zone around the mouth, as in the genera eschara, flustra, and cellulatia; and 2, loophopoda, with tentacles on a single ciliated disc. Among superficial forms, such as cristatella, plumatella, and alcyonella. The tunicata, including the ascidians and salpa, have no shells, but are enclosed by an elastic, cellu-

lose, uncalcified integument, having two apertures; the circulation is peculiar in the phenomenon of venous blood at one time pro-
ceeding from the heart to the gills, and at an-

other arterial blood from the gills to the heart, in the same vessels; respiration is effected either by a vascular ciliated pharyngeal sac, or by a ribbon-shaped gill stretched across the common visceral cavity; the nervous system is well preserved, the brains being calcified; the nerves radiate; organs of feeling, sight, and even hearing, have been described in these animals; muscular fibres, both longitudinal and transverse, are well developed. In salpa we have free swimming animals, drawing in water by one aperture and expelling it by an-

other one opposite; they are numerous in the Mediterranean and in the temperate parts of the ocean far from the shores, and are said to be phosphorescent at night; they sometimes occur singly, and sometimes in long chains or in rings; Chamisso concluded, from observing the living animals, that a generation of distinct salpa alternates with one of those in a chain; within the single individuals connected embryos were found, which, with other similar phenomena, led to the interesting work of Steenstrup on the "Alternations of Generation;" the solitary salpa are sexless, and are propagated by internal germs or buds, and are inferior to the associated forms, which have reproductive organs; the latter produce each a single young one. The ascidians have a sac-like body, with two apertures generally near together;
the branchial sac is large, the opening of the oesophagus situated at the bottom; they are mostly attached, and propagate both by eggs and buds, the male and female organs being on the same individual. They are both simple and compound. Those young which originate from eggs move free in the early stage, and have a long tail which is lost when they fix themselves by the opposite extremity; in the compound forms, larvae of this description may enclose a group of eight united ascidians, by their division laying the foundation for a colony while yet free, capable of greater multiplication by further gemmation. Ascidians are found from the tropics even into the arctic regions, and some of the compound forms are brilliantly phosphorescent. The non-pedunculated single ascidians were known to Aristotle, and were called by him tethron; sometimes called barnacles, these animals are ten seen attached to rocks, shells, crabs, and other bodies; though several may be found in a group, they do not form a compound body with a common external covering; they are occasionally found attached to a shapeless mass formed by the bodies of other ascidians. The food consists of small organic particles, which are brought with the water into the branchial sac and to the oesophageal opening at the bottom.—The brachiopods, or paliobranchiata, have the body depressed, covered with a mantle, biliated and open; the branchia are not separated from the mantle; the heart is double and arterial; near the mouth are two long spirally convoluted arms (whence the name of the order) provided with cirri or cilia; the mouth is simple, at the base of the arms; the shell is bivalve, always attached either by a peduncle or by the shell, and adheres to the mantle by several oblique muscles; there is no elastic ligament at the hinge, which is opened by the arms and by internal muscles; all are aquatic and marine. They include the extrinsic spirifers, orthia and productus, with articulated calcareous shells; and the crania and lingula, the last interesting as occurring with slightly modified species and with few interruptions from the Silurian to the present epoch.

MOLOCH, or Molech, the national god of the Ammonites, who was worshipped by human sacrifices. The Hebrews were repeatedly addicted to his worship. Solomon, Induced by his foreign wives, built a high-place to him; Manasseh imitated his impious and idolatry continued from that time chiefly in the valley of Tophet and Hinnom, till the place was defiled by Josiah. Some explain the terms which are generally thought to refer to the burning of children as sacrifices to Molech, to mean only the passage between two burning pyres, or the act of leaping over a fire, as a symbol of purification, practised by many ancient nations. Milcom (1 Kings xi.; 2 Kings xxiii.) and Malecham (Jer. xlii.) are considered dialectic variations of the name Moloch, which probably signified king (Heb. melēkh).

MOLCH, an Australian iguanian reptile, of the family agamidae. The M. horridus (Gray) is the most ferocious-looking of the lizard tribe, and, though harmless, is as ugly as any of the representations of fabled basilisks and dragons. The whole body is covered with irregular plates and strong sharp spines, and the head is crowned with two very large spines; on the back of the neck are large rounded protuberances, similarly armed with granular scales and spines.

MOLOSSIA, or Molossia, in ancient geography, a division of Epirus in northern Greece, extending across the province from N. to S., partly between Athamania on the east and Thessprotia on the west. In early times it was peopled by various tribes of unknown race, with whom the Molossi, a Grecoan people who claimed descent from Pyrrhus (Neoptolemus), the son of Achilles, mingled at a later period. Though regarded as semi-barbarians, the Molossians became predominant in Epirus, and established a royal dynasty over the whole country in the last quarter of the 4th century B.C., the capital being Ambracia (now Arta), near the gulf called after it.

MOLTKE, Helmuth Karl Bernhard von, count, a German general, born at Parchim, Mecklenburg, Oct. 29, 1800. His father was a Danish general, and he was educated at the cadets' academy at Copenhagen, and at 18 became an officer. He entered the Prussian service in 1822, and after ten years of arduous studies and labors was admitted to the general staff. In 1835 he went to Constantinople, and Mahmoud II. conceiving a high regard for his genius, the Prussian authorities permitted him to serve him in improving the fortifications of Turkish cities and in the warfare against the Kurds and against Egypt. He returned to Berlin after the sultan's death in 1839, was employed for many years in staff service, and in 1856 became adjutant of Prince Frederick William, and in 1858 chief of the general staff of the army, which post he still holds. The rank of lieutenant general was conferred upon him in 1859. He planned the operations in the wars with Denmark (1864) and Austria (1866), accompanying on the former occasion Prince Frederick Charles, and on the latter King William. After the battle of Sadowa Moltke made every preparation for marching upon Olmütz and Vienna, but negotiated a five days' truce, which became the prelude to peace. He was rewarded with the order of the black eagle and the command of the Kolberg or second Pomeranian grenadier regiment. Having long foreseen the contingency of a war with France, he was ready with his plans when it suddenly broke out in 1870, and their execution resulted in the most astonishing and uninterrupted series of victories ever achieved by one great military nation over another. His system consists mainly in making the different army corps advance separately and operate simultaneously in grappling with the enemy, and he brings to
bear upon its elaboration a mind of singular clearness, a wonderful logical power, and a capacity of patient research of the highest order. Besides conferring on him the title of count and making him large donations, the emperor of Germany appointed him in 1871 general field marshal, and in 1872 life member of the upper house. In January, 1874, he was returned to the Reichstag, and in the following month delivered a speech showing the necessity of being prepared for retaliation on the part of France, which produced a strong impression. His most important work is Der deutsch-französische Krieg (Berlin, 1873 et seq.).

MOLUCAS, or Spice Islands, a group of the Indian or Malay archipelago, between lat. 3° N. and 9° S., and lon. 122° and 183° E., scattered over the sea which extends from the E. coast of Celebes to the W. coast of Papua, and from the Philippine islands on the north to Timor on the south; area, 42,946 sq. m.; pop. in 1871, 391,879 natives and 1,808 Europeans. The number of the islands is estimated at several hundreds; many of them are small and uninhabited. The large islands are Ceram, Gilolo, and Booro. This part of the archipelago is naturally divided into three clusters, viz., the Moluccas proper or Gilolo group, the Ceram group, and the Timor Laut group. The first comprehends Gilolo, Morty, Mandjoli, Batchan, Oby, Motir, Makian, Ternate, Tidore, and many other islands. The Ceram cluster, which lies in the centre of the group, contains, among others, the islands of Ceram, Booro, Ambonya, and Banda. The third cluster lies further S. between Australia and the west of Papua, Timor Laut being the principal island. Originally, and in a more circumscribed sense, the Moluccas comprehended only the small islands off the W. coast of Gilolo, including Batchan, Motir, Ternate, and Tidore; under the early Dutch dominion the appellation was extended to Ambonya and Booro, but was still restricted to the smaller isles. The outline of the coast of the Molucca islands is very irregular; in many places they rise abruptly from the water to a considerable elevation. There are many excellent harbors, but sand banks which render navigation intricate and dangerous are frequently formed by earthquakes. Nearly all the islands are mountainous, and some of them contain peaks 7,000 or 8,000 ft. high. The formation of the group is volcanic; the surface is singularly broken and indented with lofty peaks and rocks piled up to great elevations; there are several active craters and hot springs, and violent earthquakes are frequent. On account of the comparative smallness of the islands and the regular monsoons, the heat is never excessive. Cereals cannot be cultivated to any great extent, and the people subsist almost entirely upon the pith of the sago palm. The most common tropical fruits and vegetables thrive well, and sugar cane, coffee, pepper, cotton, and small quantities of indigo are grown; but the Moluccas are especially remarkable for the production of cloves and nutmegs. The breadfruit tree, the cacao, and many of the fruit trees of India are found. There are more than 400 different kinds of wood in the forests, including the lingoa (pterocarpus draco), which is admirably adapted to cabinet work. Gold is found in small quantities on Gilolo, but no other metals on any of the islands. The group has comparatively few indigenous mammals, but birds are very numerous, and the fauna presents close affinities to that of Papua. Of the mammalia there are 85 known species, including 22 bats, a baboon-monkey, a civet cat, several species of pigs, a deer, a shrew, and four marsupials, one of which is a flying opossum. Of birds there are 265 species known to inhabit the group. These comprise the cassowary, found in Ceram, the megapodi and mound makers, 22 species of parrots, and 27 species of pigeons. The surrounding seas are exceedingly prolix, and the cachalot, which yields the spermaceti of commerce, is met with; but the whale fishery, once of some importance in this region, is now quite insignificant. Pearls are frequently found on the coasts. Cloves and nutmegs are exported in large quantities; sandal wood and other valuable woods are obtained; edible birds' nests, sea slugs, and shark fins are sent to China. The imports are chiefly opium and Indian and European goods. The Dutch monopolies confined the commerce for many years within very narrow limits, but a more liberal policy is now pursued.—The Moluccas, like nearly all the islands which constitute the Indian archipelago, are chiefly inhabited by two races, the Malays and Papuans. The latter people, supposed to be of the same family as the aborigines of Australia and Papua, have been exterminated in many of the smaller islands by the Malays, and in the larger ones have only retained possession of the interior and more inaccessible parts. The Moluccan Malays, according to Wallace, form one of the five divisions of semi-civilized Malays found in the Indian archipelago. They are in possession of the lower lands and seacoasts, where they cultivate the soil or gain a subsistence by fishing. They are very expert in the construction and management of their vessels, and are greatly addicted to piracy. The Malay is the common language, and the Arabic character is employed in writing it. Mohammedanism is the prevailing religion; but some profess Christianity, and distinguish themselves by wearing black garments. The laws are chiefly founded upon the precepts of the Koran.—The Moluccas had been visited by the Arabs, and the Mohammedan religion spread among the people long before the arrival of the Portuguese in 1511. The Portuguese had only begun to form settlements when the Spanish vessels under Magalhaens arrived from the east, and a prolonged dispute arose between the two nations respecting the possession of the islands, which
MOLYBDENUM

terminated in favor of the Portuguese. A system of violence and oppression was maintained for 60 years, when the Dutch with the assistance of the natives expelled the Portuguese. The Dutch East India company early in the 17th century obtained supremacy over many of the native princes, and allowed them to retain their authority by tribute to the company. To secure the exclusive trade in nutmegs and cloves, the Dutch nearly extinguished the spice trees on all the islands except Amboyna and Banda, which two they reduced entirely under their authority. To keep up prices in foreign markets, they frequently burned whole cargoes of spices. The English were allowed at one time to have a mercantile establishment at Ambiya, when held by the Dutch; but the latter in 1622, after forcing some Chinese and Javanese soldiers by torture to make confession of a plot on the part of the English, seized on the leaders and put them to death with horrible cruelty. In common with the other Dutch East Indian possessions, the Moluccas were held by the British from 1796 to 1802, and from 1810 to 1814. In 1824 some of the more oppressive laws were repealed, and the free cultivation of the islands was allowed. The Dutch possessions are divided, in point of administration, into the three residencies of Amboyna, Ternate, and Banda. The seat of the Dutch governor general is at Amboyna.

MOLYBDENUM, a metal usually obtained from the native bismuthal (molybdenite). It is also found as a molybate of lead. Its symbol is Mo; atomic weight, 96; specific gravity, 8.6. The resemblance of the bismuthore to graphite gave the metal its name (Gr. μολυβδέαν, a piece of lead). It was first distinguished from graphite by Scheele in 1778, but was first obtained in the metallic form by Hjelm in 1782. The most complete investigations of its properties and combinations were made by Berzelius. The metal may be obtained by roasting the native sulphide in a free current of air, by which impure molybdcic acid is produced in the form of a gray powder. This is digested in the ammonia, the solution filtered and evaporated to dryness, the residue dissolved in nitric acid and again evaporated to dryness, pure molybdic acid being left. This being made into a paste with oil and charcoal and heated to whiteness, the oxygen is abstracted and the metal remains. It may also be obtained by passing hydrogen over molybdic acid at a red heat in a porcelain tube. It is a white metal, brittle, and difficult to melt. When heated to whiteness in the air or in oxygen, it forms a crystalline sublimate of molybdic acid. It is easily oxidized by nitric acid, with evolution of nitrous acid fumes, and if ignited in a stream of aqueous vapor hydrogen is evolved. Molybdenum forms alloys with tin, lead, iron, copper, silver, gold, and platinum, rendering them less fusible, more brittle, and, except the silver, whiter. It forms three oxides: protoxide, MoO; and molybdic acid, MoO₃; the dioxide, Mo₂O₅; and a third, molybdic anhydride, MoO₃. The first two possess basic characters, while the last is an active acid. The proteoxide (or sesquioxide) is obtained by dissolving molybdic acid in hydrochloric acid, and placing in the solution zinc or one of the metals capable of decomposing water, and afterward treating with excess of ammonia. The dioxide is obtained by heating a mixture of sal ammoniac and molybdate of soda and digesting the residue in caustic potassa. Molybdenum forms with bromine dibromide, tribromide, and tetra bromide, and with chlorine and sulphur corresponding salts; and there may also be formed chloro-bromides. The iodine compounds are molybdous and molybdic iodides. Molybdcic anhydride forms salts with various bases, called molybdates. The molybate of ammonium is used as a delicate test for phosphoric acid. The solution suspected to contain the phosphate is acidulated with nitric acid, and the molybdate is added. If phosphoric acid is present, either free or uncombined, a yellow crystalline precipitate is formed, consisting of molybdic and phosphoric acids in combination with ammonia. Arsenic acid forms a similar compound with ammoniacal molybdate when the solutions are boiled. A mixture of sulphuric and molybdic acids yields a beautiful purple with pure morphia or its salts. The oxygen salts of molybdenum are not well enough known or of enough importance to require notice here.

MOMBRAS, Mombaz, or Mombast, a town on a small island of the same name, in a bay on the coast of Zanzibar, in lat. 4° 6' S., lon. 39° 43' E. ; pop. of the island, about 6,000. The island is about 3 m. long and 2 m. wide; the coasts consist of steep cliffs, and the town is defended by an old Portuguese fort. The town is in a ruinous condition, and is inhabited by Arabs and people of mixed race. The bay in which the island is situated is about 5 m. long and 3 m. broad, and forms an excellent harbor. There is very little trade, and the people are exceedingly poor. The Portuguese destroyed the native town in 1505, and again in 1529; from which time they held the place till they were driven out by the sultan of Muscat in 1720. In his turn he was expelled by the natives, and from 1824 to 1826 the town was under British protection; but they abandoning it, Mombas fell again under the power of Muscat.

MOMMSEN, Christian Matthias Theodor, a German historian, born at Garting, Schleswig, Nov. 30, 1817. He studied at Altona and Kiel, was aided by the Berlin academy in his archeological explorations in France and Italy (1844-7), and in 1848 was attached to the staff of the Schleswig-Holstein'sche Zeitung. For participation in the movements of 1848-'9 he was removed from the chair of jurisprudence at Leipsic, which he had filled for two years. From 1852 to 1854 he was professor at Zürich, from 1854 to 1858 at Breslau, and from that time till...
February, 1874, professor of Roman archaeology in the university of Berlin, when he was reappointed professor of jurisprudence at Leipsic, and made rector of the university. He has published Oskische Studien (Berlin, 1845; supplement, 1846); Ueber das Römishe Münzeuweren (1850); Corpus Inscriptionum Neapolitanarum (1851); Die Stadtteiche der Lateini- schen Gemeinden Salpensa und Malaga (1855); and Römisches Staatsrecht (3 vols., Leipsic, 1871-5 et seq.). Of his "History of Rome" (3 vols., Berlin, 1854-6) five editions have appeared, the last in 1869. It has been translated into French (Paris, 1863-72), and into English by W. P. Dickson (2 vols., London, 1862-3; new ed., 4 vols., New York, 1871).

MOMOTOMBO, the loftiest volcano in the republic of Nicaragua, 7,200 ft. high, standing at the head of Lake Managua, 25 m. E. by N. of the city of Leon. It sends out constantly a light plume of smoke, and occasional showers of fine ashes. The upper 3,000 ft. of its elevation seems to be made up of ashes and scorie. A tradition that the early priests who undertook to plant the cross on its summit were never afterward heard of is the subject of a poem in La légende des siècles, by Victor Hugo. There are hot springs at its base, and a number of orifices or vents (infiemillos) on its flanks. It is a prominent landmark from the sea, and constitutes one extremity of the volcanic range of the Marrabios, which terminates in the high cone of El Viejo.

MOMPOS, or Mompos, an inland city of the United States of Colombia, in the state of Santa Marta, on the Magdalena, about 300 m. N. by W. of Bogotá; pop. about 11,600. The city is on a large island formed by the Magdalena, the Caño Loa, the Caño Sibunu, and the Caúca. The streets are very long, wide, and well kept. Some of the houses have two stories, are tile- roofed, and present an agreeable aspect. Beyond the parish church, there are three other churches attached to convents, all well built. Several primary schools were opened in 1872 and 1873. The climate is hot, humid, and generally unhealthy; the thermometer ranges for most of the year from 85° to 100° F. Alligators and mosquitoes of enormous size are common. It is rare to see a native free from goitre. The soil is remarkably fertile. The port is defended by forts of comparatively modern construction, and there is an excellent mole which protects the city from damage during the periodical swelling of the river, which in December often rises 12 ft. above its usual level. Mompos was long the principal entrepot for the whole basin of the Magdalena; and an important trade is still carried on with Ocaña, Giron, Antioquia, and the upper Magdalena, in tobacco, sugar, flour, cacao, coarse cotton fabrics, and precious metals.—The city was founded in 1540. It has experienced several disastrous inundations, especially in 1762, when the inhabitants were saved by taking to canoes.

MOMUS, in Greek mythology, the god of mockery and censure, said to have been a son of Night. Having been chosen by Neptune, Minerva, and Vulcan to decide on the merits of their respective works, he censured them all, in consequence of which he was expelled from heaven. He is generally represented raising a mask from his face, and holding a small image in his hand.

MONACHISM (Gr. μοναχία, solitary), a term denoting solitary life or retirement from the ordinary concerns of the world, with a view to the occupation of the soul with religious objects. The first type of monachism may be found in the asceticism practised by the Jewish Essenes and Therapeutæ at the dawn of Christianity. Origen gives the name of ascetes to persons who fast rigorously. It was also applied to all who habitually devoted several hours of the day and night to prayer, or who bestowed their wealth and time in relieving the sick and poor. These ascetics generally dwelt in the cities, and wore distinctive garments of a dark color, together with the pallium or cloak of the ancient philosophers. During divine service the ascetics were assigned an intermediate place between the clergy and the laity. A severer form of asceticism was the life led by anchorites or hermits. Their numbers increased very much during the 3d century, filling the mountain wilderesses of Asia Minor, Syria, and Egypt. Communities of women were organized as early as the close of the 3d century. According to Dollinger, the term μοναχίαπρον was first applied to the common abode of the Egyptian therapeutæ. It is also in Egypt that the first known Christian monasteries or monachal communities of men were formed by Paul of Thebes and his disciple Pachomius. The germ of these establishments was planted by Paul in the island of Tabenna, a little north of the first cataract of the Nile, and was developed by Pachomius, who first drew up a rule for monks in 340. Several monasteries were united under his government. Each monastery was divided into several "families," and each family pursued a distinct mechanical occupation and was governed by a prior. The family counted 40 monks, who dwelt there by threes in separate cells. Some monasteries comprised 40 families. When Athanasius in 356 took refuge in the island of Tabenna, Pachomius met him at the head of an army of monks singing psalms. In imitation of Pachomius, Ammon founded a monastery on a hill above the valley of Nithria, on the confines of the Libyan desert, where 5,000 monks soon assembled under him: and Macarius next established numerous monasteries in the desert between the Nithrian mountains and the Nile. Near Arsinoe the abbot Serapiion ruled 5,000 monks; and Rufinus says that in 356 the monasteries of Oxyrhincus contained 10,000 men and 15,000 women. The life of the inmates was divided between private prayer, public psalmody, the study of the Scriptures, the copying of manu-
scripts, agricultural and mechanical occupations, and the various offices of charity. These monasteries were great industrial schools, and those of the Thebaid served as hostelries for travellers over the desert; for each had its zenodochium in which gratuitous hospitality was exercised. Pachomius had made the study of the Bible a special duty; all his monks were obliged to know how to read and write; and in each monastery of Tabenna there was one family exclusively composed of learned men, skilled in Greek literature. These institutions were replenished constantly with the disciples of the Alexandrian schools, and reacted occasionally upon the intellectual life of the latter.

The monastic institutions of Egypt were imitated in Syria, Asia Minor, and the southern shores of the Black sea, eremitical life being in the 4th, 5th, and 6th centuries everywhere superseded by the cenobitical. St. Hilary became in 329 the father of monastic life in Palestine; Enstatius, bishop of Sebasta, propagated about the same epoch in Armenia; St. Basil about 360 spread it in the province of Pontus, and St. John Chrysostom, who found it flourishing around Antioch, extended its influence by word and example. The practices of eremitical life were never regarded with much favor either by the great church fathers or by the councils. They rather aimed at forming, by the temporary exercise of the ascetic virtues, apostolic men fitted to spread the reign of gospel truth among the city populations. With still less favor did they regard the extraordinary performances of the Sarabaites, Stylistes, Acemetes, Agonistes, and the like. From the desert, monastic institutions were transplanted to the towns, and ecclesiastical writers soon complained that many fled to the convent only for the purpose of finding there a life of ease; that the mask of piety served frequently for concealing laziness and wickedness; that excessive asceticism led many to licentiousness, insanity, despair, and suicide; that ignorance and fanaticism made the monks dangerous tools in the hands of ambitious men, and that their zeal could be turned to acts of violence against Chrysostom as well as to the destruction of pagan temples or the suppression of Arianism. The emperor Valens and several of his successors vainly sought to arrest the too rapid increase of monachism. The contemplative life led many into gross anthropomorphism, which caused their exclusion from the church. Though many censured the abuses of monachism, few were found, like Jovinian, to assail the principle. Under the growing influence of the Byzantine emperors, the eastern church, and with it eastern monachism, lost all vitality. No attempts were made to create new organizations. Traditionally all the eastern monks have followed up to the present day the so-called rule of St. Basil, and have called themselves after either St. Basil or St. Anthony. They are still numerous in all the eastern churches, and some of their establishments, as the convents of Mount Athos, are still celebrated for their literary treasures or political influence; but they have ceased altogether to be powerful agencies of religious influence. Monachism was destined to achieve its greatest successes in the West. About 340 Athanasius during his second exile went to Rome with some Egyptian monks. Later he met St. Martin of Tours, still a soldier, in the imperial city of Treves, and confirmed the latter in his resolution of embracing a monastic life. Martin founded, it is said, the first monasteries established west of the Alps, and may thus be called the father of monachism in Gaul. Cassian, his contemporary, planted another monastic colony at Marsilles, and wrote there his book "On Monastic Institutions." The disciples of St. Jerome were obliged to follow him to Bethlehem. Ambrose founded a monastic establishment at Milan, and there he converted Augustine, who in his turn became in North Africa the originator of a form of monastic life that was to live afterward in thousands of European establishments. Augustine before he became a priest lived near Carthage a semi-eremitical life with a few friends; and the rule which they then followed served as the basis of the rule adopted long afterward by the Augustinian order, or hermits of St. Augustine. After his ordination, and especially during his episcopal life, he lived in community with his brother priests; and their mode of life, together with the monastic regulations scattered through his writings served as an exemplar for the numerous houses of canons regular throughout Christendom, for the orders of Fontevrault and Prémontré, for the Gilbertine canons regular in England, the order of friars preachers, and innumerable orders of women. The Augustinian manner of living was brought over to England by Pelagius, and to Ireland by St. Patrick. Monastic establishments and schools in the time of St. Patrick sprang up around the great churches as well as institutions favorable to seclusion and study. St. Columba sent monastic colonies into Scotland, the Hebrides, and the Orkneys. The first Northmen who colonized Iceland found Irish monks there before them. St. Columbanus passed over into Gaul with 12 companions, who founded numerous similar institutions in that country, Switzerland, Germany, and northern Italy. England had flourishing cenobitical establishments in the same centuries. But in the monasteries founded in continental Europe by these Irish monks, the rule of St. Benedict of Nursia soon superseded that of Columbanus. Benedict in 529 built at Monte Casino two oratories in honor of St. John the Baptist and St. Martin of Tours, and his rule spread rapidly over all western Europe, uniting independent establishments in one great monastic hierarchy. The good effect by the monasteries of both sexes, not only in the work of conversion and education, but even in promoting agriculture and
MONACHISM

the other useful arts, met such general appro-

bation that attempts were made to subject

all the secular clergy to living in common un-
der a rule. This movement was commenced

by Chrodegang of Metz, who established the

canons regular, but, though often renewed,
could never be fully carried out. But the

esteeam in which the monastic orders were

held, and the generous benefactions of princes,

pretates, and peoples, facilitated the growth of

corruption.—For many centuries the history

of monachism presents a continued struggle of

reformers with the laxity or immorality in the

convents of their times. The first of these

reformers was Benedict of Aniane (died 821),

whose commentary on the rule of Benedict

of Nursia obtained later an equally authoritative

character. Benno, who became in 910 abbot of

Cluny, founded the congregation of Cluny,
a main pillar of the reformatory party, which

was exempted by the pope from episcopal

jurisdiction, and received the right of choosing

an abbot with quasi-episcopal rank. Romwald

founded the congregation of Camaldoli in 1015,

Gaubert that of Vallombrosa in 1036. The

Cistercians owed to St. Bernard of Clairvaux

so great a celebrity, that they were soon intro-

duced into nearly all the European countries.

The order of Grammont sought to excel in

ascetic rigor, and that of the Carthusians ad-

hered more faithfully than any other order to

its original spirit. The order of St. Anthony

(1095) and the Hospitalers (1078) devoted

to the nursing of the sick, the order of

Fontevraud (1094) to the correction of lewd

women, and the Trinitarians (1198) to the

redeeming of Christian prisoners. Even the

warlike tendencies of those times sought a

union with the monastic spirit by the establish-
mement of several orders of knights. The large

increase of the number of orders excited forth-

much opposition, and the Lateran council in

1215 decreed that no new order should be

established. Yet the same period witnessed

the birth of a new class of orders, the men-
dicants (Franciscans, Dominicans, Carmelites,

Augustinians, and several others). The dangers
to which the church was exposed on the part

of new dissenting ecclesiastical bodies re-

quired a more zealous agency, especially among

the lower classes. The mendicants tried to

supply this want. The rapidity of their suc-

cess was astonishing, and very considerable
privileges were conferred on them by the

pope. The Franciscans and Dominicans soon

took the lead. Both created for themselves a

numerous and influential party among the laity

by the establishment of tertians, who bound

themselves to the ascetic and devotional regu-
lations of the order, without assuming its garb

or entering the convent. Both secured also

several chairs at the theological schools, in spite

of the opposition of the secular clergy; and

the most distinguished representatives of this

and the following centuries (Thomas Aquinas,

Bonaventura, Albertus Magnus, John Duns

Scotus, Alexander of Hales, &c.) were either

Dominicans or Franciscans. Several of their

members filled the highest ecclesiastical posi-
tions, even the papal chair. They raised mona-

chism to the zenith of its power, influence, and

prosperity. As Robert Grosseteste and others

affirm, the mendicants owed their popularity

and success to the purity of their lives in an

epoch of general monastic degeneracy. But

the very influence which they obtained with

princes and peoples, and the wealth that was

forced upon them in consequence, hastened

their own decay. Toward the close of the

middle ages the name monk was often used

as synonymous with rudeness and ignorance.

Reformatory attempts were made in every

century; new orders, as the Jesuates, Bright-
tins, Servites, Hieronymites, and others, were

founded; but their influence was weak, and

frequently after an existence of 50 or 100 years

they themselves departed from their primitive

standard of rigid asceticism. The councils

of Constance and Basel devised for a reformation

of monasticism some highly important mea-

sures, which however could only be carried out

in a few places. The Beghards and Beguines

exhibited a freer and less hierarchical spirit;

and their associations and principles were further

developed by the Brethren of the Free Spirit.

—The reformation of the 16th century consti-

tutes another turning point in the history of

monachism. The best and most influential

men in the church cordially joined in the

demand for a thorough reformation; they

admitted that the crisis had been in part

occasioned by the corruption of the clergy, and

they urged in particular the necessity of a

reformation of the religious orders. The

internal history of nearly every order records,
at this point of time, strong resolutions,

as the result of an enforcement of the primiti-

tive rules. In the most powerful and in par-

icular the Franciscans, the more rigorous

party achieved a complete and permanent suc-

cess over those inclined toward laxity, and

several new reformed congregations branched

off from them, among which the Capuchins

were the most prominent. The council of

Trent defined the usefulness of monastic estab-
lishments, and regulated their possessions, in-

ternal administration, and the election of supe-
riors, provided for annual assembles, and ex-
tended the rights of the bishops with regard

to the inspection and supervision of the

convents. New orders also arose in the church

from the very need of reform, and bore the

impress of the times. The monastic institu-
tions of former days had been, as religious

communities, chiefly contemplative. Preach-
ing, teaching, visiting the sick and poor, and

similar objects formed the occupations of the

new orders. The best known of these organi-
zations are the Theatines, Barnabites, Jesuits,

and Oratorians of St. Philip Neri. The French

Oratorians, the Lazarists, Sulpicians, Redemp-
torists, Passionists, and other congregations
MONACHISM

are of later date. In France the religious wars of the 16th century, the degeneracy of most of the monastic institutions, the quarrels between Jansenists and Jesuits, and other causes had begotten a decided aversion to monachism. This determined Vincent de Paul to found a society of regular clerks, who, under the name of Lazarists or Priests of the Mission, have wielded a great influence in France and elsewhere; and this too determined M. Olier to give a similar organization to the Sulpicians. Of all these new orders the society of Jesus has had the most celebrity. It was founded on the principle of absolute devotion to the church and its visible head the pope. No order ever carried out its fundamental principle more faithfully, and in all subsequent contests of the Roman Catholic church the Jesuits stood in the front rank. The culture of secular literature, against which in the middle ages some founders of monastic orders had expressly warned their members, showed itself after the 16th century so great a necessity, that it was practically observed by all, though but few gave it special attention. Of these few the Jesuits, the French Oratorians, and the Benedictine congregation of St. Maur hold by universal consent a prominent place among the great literary societies of the world. A more general attention was given by the religious orders to the cause of education, especially to primary instruction. Many congregations, both male and female, were instituted for this sole purpose, especially in France, and a large number of primary schools have ever since been under their direction. Foremost among these bodies, besides the Sulpicians and Lazarists, who are devoted to the education of the clergy, are those popular educators, the Brothers of the Christian Schools, the Ursulines, Visitation Nuns, and Sisters of Charity.—The great losses which the Roman Catholic church suffered by the reformation directed the attention of the monastic orders to the foreign missionary field. Most of the great orders, especially the mendicants and the Jesuits, engaged in it with great zeal and emulation. The Jesuits took, in addition to the three common monastic vows, a fourth, binding them to go as missionaries to any country where it might please the pope to send them. The extent of their missionary operations in Europe, Asia, Africa, and America excelled anything the Roman Catholic church had done in this field before. (See Missions.) The great majority of the Roman Catholic missions in all pagan countries have ever been conducted by the members of religious orders or congregations.—In the 18th century the productivity of the church, as regards monachism, greatly decreased. The Redemptorists or the congregation of the Most Holy Redeemer, founded by St. Alfonso di Liguori, sprang up during this time to fill the gap left by the suppression of the Jesuits. Most of the orders in the second half of that century made but a feeble resistance against the all-pervading rationalism. Joseph II. suppressed all convents of monks not occupied in education, pastoral duties, or the nursing of the sick; and many Catholic writers demanded the entire extirpation of monachism as both an outgrowth and a promoter of fanaticism. Partly to this outcry, but principally to the pressure brought to bear on the court of Rome by the Catholic powers, was due the suppression of the Jesuits in 1773. The French revolution soon afterward endangered the existence of monachism in many of the European states, but with the downfall of the Napoleonic rule its prospects began to brighten. Pius VII. in 1814 restored the Jesuits, who rose again to considerable influence, wherever they were not forcibly suppressed. (See Jesuits.) In the countries of the Latin race, both in Europe and America, the fate of monachism was closely allied with the political strife of the conservative and the liberal parties; and as a number of new religious communities were formed, the latter subjecting it to prohibitive rules or suppressing it altogether. In Portuguese and Spanish America the suppression of the Jesuit schools in the last century had left the upper classes and the clergy in particular with very inadequate means of higher education. The ignorance and corruption which soon crept into conventual establishments served as a powerful argument for their gradual suppression during the present century. In Italy the great wealth of the monastic body, and the belief that they had outlived their period of utility, caused their final abolition in 1878. They may also be said to have been extinct in Portugal since 1834, and in Spain since 1835. In France alone the vicissitudes of political rule in no way affected the growth of monastic institutions. Since 1848 even the liberals have accustomed themselves to accord the right of association to the members of religious orders. Nearly every one of the old orders reestablished itself in France; and as new congregations were formed, there is at present a greater variety of monastic institutions in that country than any other state has ever possessed. Next to France, they are most numerous, wealthy, and influential in Belgium, where, as in France, public instruction is to a great extent under their control. According to the official census of 1866, there were in Belgium 178 communities of men with 2,051 members, and 1,144 communities of women with 15,205 members. They partook, throughout the British possessions, the United States, and Holland, of the blessing of truly liberal institutions, and peaceably lived in accordance with their rules, from which public opinion demanded only one departure, that no member wishing to leave their establishments should be restrained from doing so. Austria protected them, but kept them till 1848 under a bureaucratic guardianship, which has since been abandoned. In 1878 the number of convents and monasteries in that empire was about 950, with 8,500 monks.
and 5,700 nuns. The revolution of 1848 procured them freedom in many other German states where before they had been either suppressed or tolerated under great restrictions; and even those states whose codes retain laws against their admission in general, as Sweden, Denmark, and Saxony, admitted the sisters of charity. But in 1873 the German imperial diet suppressed the Jesuits, Redemptorists, brothers of the Christian schools, and sisters of charity. The Russian government has also practically extinguished all Roman Catholic establishments; but Turkey has become a prominent field for their missionary operations. —The number of monastic associations founded since the beginning of the 19th century exceeds the number founded during any other period of equal length. Most of them belong to France, and several have already attained a considerable extension. A peculiar feature which characterizes them as the offspring of the present age is, that they aim at providing for the needs of the people. A large number of them are devoted to the instruction of youth. Such are the "Ladies of the Sacred Heart," and several congregations of school brothers and school sisters. Many others bind themselves to the service of the sick and the poor, as the "Little Sisters of the Poor," the most numerous and popular of them. Not a few cultivate the mission field; either the foreign missions, as the Piacus society, the Oblates, the brothers and the daughters of Zion (both for the conversion of Jews, the latter consisting exclusively of converts); or the home missions, as the Paudiats, established in 1858 at New York. The general advance of culture has deprived the religious orders of the monopoly of education and their former scientific prominence. Still the Jesuits' schools in Italy, Germany, France, and England are not unworthy of their former reputation. In respect to their moral condition, Roman Catholics admit the existence in some places of considerable degeneracy. In some convents also the ancient constitutions have fallen more or less into disuse. The regular connection of the general superiors with their subordinates has been in great part interrupted, and the holding of general assemblies has ceased. Pope Pius IX., at the beginning of his pontificate, proclaimed it as one of his chief tasks to carry out a thorough reform of monastic orders; and in some orders, as the Dominicans, an extensive reformation has since taken place. The aggregate number of men belonging to the various religious orders and congregations in 1862 was about 120,000; the communities of women contained 189,000. —The reformation of the 16th century rejected the monachism of the Roman Catholic and the eastern episcopal churches. In the church of England and the Protestant Episcopal church in the United States, sisterhoods and even brotherhoods have been formed at various times, and have of late increased in number under the auspices of what is commonly called the high church party. Since the beginning of the 19th century both the "Evangelical" and the "High Lutheran" schools of Germany have approved of the establishment of houses of deacons and deaconesses, also called brother houses and sister houses, the inmates of which associate for the purpose of teaching, attending the sick, taking charge of public prisons, &c. Institutions of this kind are rapidly spreading in Germany and the adjacent countries. (See Dramoxas.) —The most important works on the history of monachism in general are: Hickey, De Monachia libri VI. (Zurich, 1588, 1609); Helyot, Histoire des ordres monastiques (Paris, 1714—19; new ed., with an additional vol. on the modern history of monachism, by Migne, 4 vols., 1849); and Döring, Geschichte der Mönchsaorden (2 vols., Dresden, 1828). The most comprehensive work on the subject is Montembert's Les moines d'Occident (3 vols., Paris, 1860—67; 3d ed., 1888; English ed., Edinburgh, 1861—7; German ed., Ratisbon, 1868). Another extensive work has long been in preparation by Dom Gueranger, superior of the French congregation of Benedictines. (See Religious Orders.)

MONACO, a small principality of Italy, bounded S. by the Mediterranean, and surrounded on all other sides by the French department of Alpes-Maritimes, between Nice and Ventimiglia. At present it consists only of the town of Monaco and a small portion of the adjoining territory, including the town of Monte Carlo; total area about 6 sq. m.; pop. in 1867, 3,127; of the town, 1,887. It formerly extended about 5 m. along the coast and about 3 m. inland, and consisted of the communes of Monaco, Mentone, and Rocebruna. The principal products are fruit and oil. The Genoese family Grimaldi was in possession of this territory under the protectorate of various governments from the 10th century until the early part of the 18th, when, by the marriage of the sole heiress of the name, it passed into the hands of Jacques de Goyon-Matignon, count of Thorigny. Under his grandson Honoratus IV., it was united with the French republic in 1793, but was restored to him and placed under the protection of Sardinia in 1815. The latter government acknowledged the independence of the principality, and reserved to itself only the power of garrisoning it and of appointing the military commander of the town of Monaco. Florestan I. protested in vain in 1848 against the annexation of the communes of Mentone and Rocebruna by Sardinia, and opened negotiations with foreign governments for the sale of his rights. He died in Paris, June 20, 1856, and was succeeded by his son under the name of Charles III., who in 1861 ceded to France his claims upon Mentone and Rocebruna, receiving an indemnity of 4,000,000 francs. In 1868 the pope separated Monaco from the diocese of Nice; in return for which the prince agreed to establish a Benedictine abbey, the abbot to exercise episcopal functions in the principality.
MONAD

In 1869 he abolished all taxes, and his revenue is now derived entirely from the rent of the casino where gaming is carried on. The climate is considered very favorable for persons afflicted with pulmonary complaints, and it has become a rival of Nice as a watering place.

MONAD (Gr. mono, unity), in philosophy, a word used by the Neo-Platonists of the early ages of Christianity, and especially by Origen, to express an idea of Divinity, and also the union of the Divine Spirit with matter. According to them, the soul was created before all other beings, and, being made divine by the knowledge of the monad, became Christ; a doctrine which, according to some writers, is the basis of Arianism. Long after this the word was used by Leibnitz to designate the primordial elements of all matter. According to him, monads are material points, possessing different degrees of consciousness and intelligence. The monad is simple, without extent, incorruptible, and so constituted that its whole future is contained in its beginning. (See Leibnitz.)—In the new chemistry the monatomic elements, such as hydrogen, chlorine, and potassium, whose molecules are capable of uniting only with single molecules of other elements, are called monads; while other elementary molecules, from their capacity to unite with two or three more molecules, are called diads, triads, &c. (See Atomic Theory.)—A number of infusorial organisms have received the name of monads. Some of these manifestly belong to the animal kingdom, some to the vegetable, while of others it is difficult to say to which kingdom they belong. The first classification was by the Danish naturalist O. F. Müller, who arranged under the same genus (monas) the mere moving specks that are developed in infusions, whether in vessels allowed to stand, or placed between slips of glass under the microscope, and also certain of the most elementary and smaller of the ciliated infusoria, of which the monas lens is the most abundant representative. Ehrenberg in a subsequent classification placed certain organisms containing cells in their interior among polynuclear infusoria, and called them monads. More recent observers regard them as belonging to the vegetable kingdom, ranking them among the algae. The development of the monas lens from bacteria, and their subsequent transformation into amoeba, and finally into bacteria, is a subject of rare interest, which has been pursued by Haeckel, Pinceau, Pouchet, Bastian, and others. (See ANIMALCULES, INFUSORIA, PROTOPLASM, AND SPONTANEOUS GENERATION.)

MONADNOCK, Grand, a mountain in Cheshire co., New Hampshire, near the S. W. corner of the state. The base covers an area of 5 m. by 3, and the altitude is 3,156 ft. above the level of the sea. Several minerals are found on and around the mountain, and it contains talc, mica, and slate, distinctly stratified. From a distance, its summit appears of a rounded form, free from rocks and mural precipices. Many streams of water issue from Grand Monadnock, and from its top 30 ponds are visible, some of them large enough to contain islands of 8 or 10 acres.

MONAGHAN, an inland county of Ireland, in the province of Ulster, bordering on Tyrone, Armagh, Louth, Meath, Cavan, and Fermanagh; area, 498 sq. m.; pop. in 1871, 112,765. The surface is in general hilly, except in the S. E., which is level, and forms the northern limit of the great central plain of Ireland. The principal mountains are the Slieve Beagh range, whose highest summit is 1,554 ft. above the

MONAGHAN

733
MONASTERY

the sea. The chief rivers are the Blackwater, Fane, Glyde, and Finn. There are several lakes, the largest being Muckno, or Barrac Lough, which is about 3 m. long and 1 m. broad. The soil is moory and peaty in the elevated districts, but fertile in the central and southern. The staple manufactures are linen, woollen, and earthenware. The minerals are iron, lead, coal, slate, marble, and building stone. The chief towns are Monaghan, the capital (pop. about 4,000), Clones, Castle Blayney, and Carrickmacross. It is traversed by the Ulster canal and various lines of railway. The county was a part of the grant made by Henry II. to De Courcy, was recaptured by the native chiefs, and in the reign of Elizabeth was erected into a shire.

MONASTERY (Gr. μοναστήριον, a house of retirement), the place in which monks or nuns live in seclusion. (See MONACHISM.) In the beginning monasteries were to be found only in solitary places; after a time some were built outside the walls of cities, and after the 6th century the cities themselves became the abode of cenobites. The growth of monasteries for women kept pace with those for men. St. Anthony built one for women in Egypt and placed his sister over it; St. Pachomius did the same in Palestine. St. Basil erected several similar houses in Pontus and Cappadocia. At Rome St. Constantia founded one near the church of Santa Agnese, and Marcella another near that of San Lorenzo. At the same epoch St. Eusebius of Vercelli built a monastery for women near his cathedral, and St. Ambrose another in Milan; and St. Augustine a little later placed his sister at the head of a monastery in Africa. Similar establishments increased rapidly in Western Europe. In both the East and the West the great religious orders had numerous though separate houses for both sexes. The western monasteries of the middle ages became, like those of Egypt and Palestine, so many little towns, containing all the industries necessary for their own subsistence. Not unfrequently, too, the neighboring peasants drew from the monks the necessaries of life and built their huts in close proximity to them. Such were the famous convents of St. Gall, Fulda, Clany, Cliontorgh, and Clairvax, as well as the great monastic establishments of the British isles; and such are still the monasteries of the East.—These houses are called abbeys when governed by an abbot or abbes, priories when ruled by a prior or prioress; and when the superior has no such distinctive title, the house is called simply a monastery, convent, or nunnery.

MONASTIR, or Bitolia, a town of European Turkey, in the vilayet and 80 m. W. N. W. of Salonica; pop. about 53,000, chiefly Greeks and Bulgarians. It is situated in the valley of a tributary of the Vardar, 1,700 ft. above the sea, and surrounded by lofty mountains. The town contains many mosques and a fine bazaar with thousands of shops. It has in recent times considerably increased in importance as a great military and commercial centre. Large quantities of manufactured goods are imported from Salonica, Constantinople, Belgrade, Trieste, Vienna, and other places, and exported to the interior. A Turkish governor and a Greek metropolitan bishop reside here; the diocese is still called Pelagonia, the ancient Greek name of the district.

MONBODDO, James Burnet, lord, a Scottish jurist, born at the family seat of Monboddo, in Kincardineshire, in 1714, died in Edinburgh, May 20, 1799. He graduated at the university of Aberdeen, and was sent to Groningen to study law. In 1738 he returned to Scotland, and practised at the bar till 1767, when he was made a judge. His principal works are: "A Dissertation on the Origin and Progress of Language" (6 vols. 8vo, 1774—92), and "Ancient Metaphysics" (6 vols. 4to, 1778). He especially admired the civilization of Greece, but maintained that the savage state was happiest, that men originally possessed no higher faculty than beasts, and that the orang outang is of the human species.

MONBUTTOO, a country of central Africa, bordering on Nyam-nyam, Moruvoo, and Akka, between lat. 3° and 4° N., and lon. 28° and 29° E.; area, about 4,000 sq. m.; pop. estimated by Schweinfurth in 1870 at 1,000,000. It is generally a table land 2,500 to 2,800 ft. above the sea, with gentle elevations in some places 100 ft. above the beds of the streams. It is traversed in the north by the Kebabli river, which is joined by the Gadda flowing in from the southwest. They form the Welle, which proceeds west along the southern portion of Nyam-nyam, and is enlarged by numerous tributaries, that enter from the western Europe. In the upper course the more easterly of the two arms, which, uniting in Baghimi under the name of Shary, are the source of Lake Tchad. The country is described as very beautiful, with vast groves of plantains, oil palms, and other trees, and a delightful verdure. The spontaneous production of fruits and tubers in profusion limits cultivation to the narrowest bounds, and almost the only products requiring attention are sesame, ground nuts, sugar cane, and tobacco. The breeding of cattle is not practised by the Monbuttoo; vast numbers of goats are stolen from their neighbours, but there is no attempt to rear them; and, excepting dogs and poultry, they have no domestic animals. The people are of a lighter tint than other known nations of central Africa, and Schweinfurth compares the color of their skins to that of ground coffee. They differ from other negroes also in the greater length and curve of the nose. Weaving is unknown to them; the men clothe themselves with the bark of the fig tree, and the women go almost entirely naked. They practise circumcision, and polygamy is unlimited. They are ingenious workers of copper and iron, expert wood carvers, and display some facility
in the manufacture of pottery. Their hunting expeditions supply them with a great abundance of wild meat; but, according to Schweinfurth, their cannibalism is "the most pronounced of all the known nations of Africa." An important article of traffic is ivory, which is a monopoly of the king.

**MONCK**, an electoral district of Ontario, Canada, in the S. part of the province, bordering on Lake Erie; area, 875 sq. m.; pop. in 1871, 16,179, of whom 6,575 were of German, 5,046 of English, 3,080 of Irish, and 1,570 of Scotch origin or descent. It comprises parts of the counties of Haldimand, Lincoln, and Welland, and is traversed by the Grand Trunk, Canada Southern, and Great Western railways.

**MONCREIFF (Wellwood)**, Sir Henry, a Scottish divine, born at Blackford, Perthshire, Feb. 6, 1750, died in Edinburgh, June 14, 1827. He was the son of the Rev. Sir William Moncreiff, and assumed the name of Wellwood in the latter part of his life. He was educated at Glasgow and Edinburgh, was ordained in 1771, and was minister in Blackford as successor of his father till 1775, when he was appointed minister of St. Cuthbert's, Edinburgh. He early connected himself with the evangelical party in the church, and became in time its leader. His principal works are: "Discourses on the Evidence of the Jewish and Christian Revelations" (Edinburgh, 1815; "Account of the Life and Writings of Dr. John Erskine" (1818); and "Sermons" (3 vols. 8vo, 1829-31), with a memoir by his son.

**MONCTON**, a town and port of entry of Westmorland co., New Brunswick, Canada, at the head of navigation on the Petitcodiac river, and on the Intercolonial railway, 89 m. N. E. of St. John; pop. in 1871, 4,810. It is beautifully situated and has a fine harbor. The number of vessels cleared during the year ending June 30, 1873, was 17, of 1,563 tons; entered, 18, of 1,987 tons; value of exports, $15,321; imports, $17,057. The town contains the general offices and principal workshops of the railway, and has manufactories of iron castings, steam engines, machinery, tobacco, leather, wooden ware, &c., two branch banks, several hotels, a weekly newspaper, a telegraph office, and four churches.

**MONDAY** (Lat. Lunae Dies, Fr. lundi, Ger. Montag, the day of the moon), the second day of the week, which derives its designation from the Romans, who gave the names of the sun, moon, and five planets to the seven days in modern use.

**MONDÒNEO**, a city of Galicia, Spain, in the province and 30 m. N. N. E. of the city of Lugo; pop. about 7,000. It is built in the form of an amphitheatre on the slope of three mountains, one of which is the Monte Infesta, at the edge of an oval valley, watered by three streams, tributaries of the Masma. The streets are irregular, and the houses mainly of antiquated appearance. The walls are in good preservation. The cathedral, begun in 1221, is a massive Corinthian structure. An ancient castle stands on an eminence, and its batteries command the town. The chief occupations are agriculture, cattle rearing, cotton and linen weaving, and tanning. The French sacked Mondoñedo in 1809.

**MONDOVI**, a town of Piedmont, Italy, in the province of Coni, on the right bank of the Elero, 1,810 ft. above the sea, and 53 m. W. of Genoa; pop. about 10,000. It is partly on a hill, is walled, and has a citadel. The streets are adorned with many handsome edifices at Long which is the cathedral of San Donato. It is the seat of a bishop, and has two gymnasias, a technical school, an episcopal seminary, and other schools and charitable institutions. The manufactures are of woollens, silks, &c. The city was founded in the 12th century by the people of the surrounding villages, as a place of refuge during the civil wars. It remained an independent republic till 1596, when it submitted to Amadeus of Savoy, titular prince of Achaia. On April 21, 1796, it was the scene of a battle between a portion of Bonaparte's army and the Sardinians under Colli, in which the latter were defeated with the loss of 2,000 men and 8 guns. In 1799 the city was fearfully punished for rising against the French.

**MONE, Franz Joseph**, a German scholar, born at Mingolsheim, Baden, May 12, 1796, died in Carlsruhe, March 12, 1871. He studied at Heidelberg, and was professor there till 1827, when he became professor of edifices at Long vain; but after the revolution of 1830 he returned to Heidelberg, and in 1835 became director of the Baden archives. His works include Geschichte des Heidenthum's im östlichen Europa (3 vols. 1822-3); an edition of Reinardus Vulpes (Stuttgart, 1892); Uber-sicht der niederländischen Volkskultur alterer Zeit (Tübingen, 1888); and Die galische Sprache und ihre Brauchbarkeit für die Geschichte (Carlsruhe, 1851).

**MONEY** (Lat. and Ital. moneta), the currency of the realm or of the country; the standard of payment, whether of coins, circulating notes, or any other commodity. Anything which freely circulates from hand to hand, as a common, acceptable medium of exchange in any country, is in such country money, even though it cease to be such, or to possess any value, in passing into another country. In a word, an article is determined to be money by reason of the performance by it of certain functions, without regard to its form or substance. Money has been termed by Mr. Henry C. Carey "the instrument of association," and the same writer has said of it that it is "a saving fund for labor, because it facilitates association and combination, giving utility to billions of millions of minutes that would be wasted did not a demand exist for them at the moment the power to labor had been produced." Baron Storch termed money "the marvellous instrument to which we are indebted for our wealth and civilization." Mr.
Thorold Rogers has said: "Just as the development of language is essential to the intellectual growth of a people, so is a medium of exchange to civilization." Aristotle says of it, "that it exists not by nature, but by law." How true is this doctrine, or at least how potent is the law under a civilized government in imparting the quality of acceptability for the payment of debts and the purchase of commodities to that which it recognizes as money, is clearly proved by the operations of the bank of Venice during several centuries, throughout which time its deposits, which were never payable, but only transferable on the books of the bank, were at a premium over coins, because they were the standard of payment furnished by the state and used for all large transactions. Indeed, this bank money was that which established the money of account and in which the value of all coins was expressed. Further, on the testimony of Thomas Baring, we are assured that it was found impossible during the crisis of 1847 in London to raise any money whatever on a sum of £60,000 of silver. During a similar crisis in Calcutta in 1854 it was equally impossible to raise even a single rupee on £200,000 of gold. The former was not a legal tender above 40 shillings, while the latter was not so for any sum whatever. About 1855 Holland adopted silver as the only legal tender at a fixed value, but attempted to coin gold coins having no such value, this only being regulated by the market price from day to day. After 200,000 florins (about $80,000) had been coined, the demand entirely ceased.

—Very dissimilar substances have been made to serve as money. The Jews, in addition to their ordinary money of shillings, talents, and drachms of silver, had "silver money." Cattle were used as money in ancient Greece and in Rome; and hence the word pecuniary, from pecunia, and this from pecus, cattle. Before the introduction of coined money into Greece there was a currency of "spits" or "skewers," of which six were a drachm (δραχύς, originally δραχμή, a handful); they were probably nails of iron or copper. The Lacedemonians and Byzantines and the people of Czazomena used iron money. Among the most ancient existing specimens of coin are those of electrum, an alloy of gold with one fifth silver. Gold, silver, and copper were coined by the Greeks and Romans. Tin was coined by Dionysius I., tyrant of Syracuse, and Roman and British tin coins are known to exist. Early leaden money is mentioned; a leden stater is preserved in the British museum, and leaden money is now current in the Burman empire. Platinum was coined in Russia from 1828 to 1845. Numa Pomplius, king of Rome about 700 B. C., made money both of wood and of leather. Under the Cezars lands were made money. The Carthaginians had a kind of leather money. The emperor Frederick Barbarossa during his contest with Milan (1158–62), and John the Good, king of France (1360), also issued leather money. Under William I. of Sicily (1154–66), the Sicilians were compelled to give gold and silver in exchange for leather money. In 1574, when the city of Leyden was besieged by the Spaniards, leather money was issued. The British museum has a specimen of a sequin in leather of Francesco Cornaro (1566). In the 18th century Nicolò and Matteo Polo found a money in use in China which was made of the middle bark of the mulberry tree, cut into round pieces and stamped with the mark of the sovereign; this money it was death to counterfeit or refuse to take in any part of the empire. In Britain, at as late a date as the Norman conquest, two kinds of money were in use, known as "living money" and "dead money." The former consisted of slaves and cattle, which were usually transferred with the soil, and the latter of metal. Montesquieu notices the existence among the inhabitants of the coast of Africa in the 18th century of an "ideal money," "a sign of value without money," the unit being the macoute, which was subdivided into tenths called pieces. This money of account had its origin, as appears from later testimony, in the macoute; a piece of stuff, a fabric; and Mungo Park says that in the early intercourse of the Mandings with the Europeans, the article which attracted most attention was iron, on account of its high utility in making implements of war, &c. Iron soon became a standard of payment, and gave rise to a money of account; and any commodity which was supposed to be of the value of a bar of iron was called a bar, as a bar of tobacco, &c. When the South sea islands were discovered the natives first exchanged their products with the Europeans for beads or anything gaudy which was offered to them; but they soon discovered the value of iron utensils, and they now freely exchanged anything they had for axes, hammers, nails, &c. Axles were eventually held in such estimation that they became a standard of payment and the basis of a money of account, the value of other articles being stated at so many axes. Cowry shells (cypraea moneta) are used in India, the Indian islands, and Africa, in the place of small coin. In 1851 more than 1,000 tons were brought from India to Liverpool to be exported to the coast of Africa in exchange for palm oil. In Bengal a century ago 2,500 cowries were worth a rupee (46 cts.), and at the present time 3,200 are worth this sum. According to Dr. Barth, in Bornoo, central Africa, the ancient standard of the country was the pound of copper; but it has long since fallen into disuse, although the name roti still remains. The prices of commodities are still reckoned in the roti, although cotton strips and shirts, cowries, and Austrian and Spanish dollars have become the mediums of exchange, their value being expressed in rotis. In India cokes of tea and in China pieces of silk, pass as money. Salt is the current money of Abyssinia, codfish of Iceland and Newfoundland. At the great fair
annually held at Nizhni Novgorod in Russia, the price of tea has first to be made known before the prices of other commodities are fixed, it thus becoming a standard by which all exchanges of merchandise are regulated. The skins of wild animals were used as money by the ancient Russians and by some of the Indians on this continent; and even by the people of Illinois at an early day raccoon and deer skins were so used. In 1574 quantities of pasteboard were coined in Holland. Of the aboriginal money of the American continent, from the mounds in and adjoining the valley of the Mississippi, specimens have been obtained composed of lignite, coal, bone, shell, terra cotta, mica, pearl, carnelian, chalcedony, agate, Jasper, native gold, silver, copper, lead, and iron, which were fashioned into forms evincing considerable skill in art. Cocoanuts were used as money in certain parts of the American continent when the Europeans first visited it. Wampum was used by the Indians as currency, and about 1635 was the precious stone among the colonists of Massachusetts, was a legal tender, and was even counterfeited. About the same time corn and beans were used, and indeed a general barter currency was in vogue, and musket balls passed for change at a farthing apiece, and were a legal tender for sums under one shilling. Codfish was also used. The accounts of the New Netherlands were in 1662 kept in wampum and beaver skins; and in Virginia about the beginning of the 18th century the receipts issued for tobacco deposited in warehouses passed current as money. Adam Smith mentions that in Scotland about 1776 it was customary for workmen to carry nails as money to the bake shop and the ale house. Notched wood was used at one time in England. "In the British West India Islands," says Mr. Madden, author of "Coins of the Jews," "pennies, a slice of bread, a pinch of snuff, a dram of whiskey, and in the central part of South America soap, chocolate, cocoanuts, eggs, &c., serve the same purpose. Association with his fellow man being one of the first and most imperative needs of men, he thus finds, amid a variety of things, some one or more which will serve as the instrument of association."—R. H. Patterson, an eminent Scotch writer, has traced the origin of metallic money in the East through the tendency of man in the then primitive state of society to accumulate the precious metals at a time when there was little wealth beyond that of flocks and herds, crops of grain, and other personal property; and he goes on to say: "Next, as all men valued these metals, kings began to collect their revenues in that form. They coined the metal and made it receivable as tribute or taxes. This fully established the exchangeable value of the precious metals. It created a new demand for them, it rendered them indispensable in a department of national life where they had not previously been required; thenceforth all men needed them every year to pay the king's dues. Thus they became a circulating medium. A man who had more oxen or grain than he needed for his own use, sold those commodities to others, receiving coins in return, which coins he could store for ever, which were useful to pay taxes, and when he so needed to purchase the labor or productions of others." "But," he adds, "the invention of money by no means put an end to payments in kind and the process of barter. It only supplemented them. Even in England until the reign of Edward I. the taxes were paid in kind to a large extent, if not entirely; and to much later date military or other personal service to the state was accepted in lieu of taxes of any kind." As monarchs originally established coinage, so throughout all subsequent time the monarch or the state has claimed as among the highest of his or its prerogatives all control over "the current money of the realm." With coins this function has almost universally been directly exercised by the supreme authority, while with circulating notes, the prerogative still being claimed, the exercise of the former one has generally been delegated to banks. The earliest recorded mention of the precious metals is found in Gen. xiii. 2, when Abraham returned from Egypt "very rich in cattle, silver, and gold." In xvii. 12 we find the expression, "he that is born in the house or bought with money of any stranger." The earliest account of a purchase and sale is given in Gen. xxvii., when Sarah the wife of Abraham being dead, he bought from Ephron a field in Machpelah for a burial place for her, and he "weighed to Ephron the silver which he had named in the audience of the sons of Heth, four hundred shekels of silver, current money with the merchant." It will be observed that this current money was not counted, but was weighed, the money of that day being pieces of silver cut to certain weights, as shekels and talents, but not coined. The invention of coinage has been attributed to the wife of Midas, a legendary king of Phrygia, although it is quite probable that this was merely the introduction of the art from some other country more advanced in civilization. By some of the highest authorities the balance of testimony at present existing, so far as it can be traced, is regarded as in favor of the Lydians (about 1200 B. C.) as the inventors, and with this view both Herodotus and Xenophon of Colophon agree. In the opinion of Mr. Madden, the earliest electrum coins have the appearance of greater antiquity than any in the whole Greek series; and it seems more probable that the invention was of Asiatic origin, as the part of Asia to which this electrum class belongs was at this early period subject to the Lydian kings. By some Greek writers the invention is attributed to Phidon, king of Argos in the 8th century B. C., and by others to the people of Ægina. Phidon is now believed only to have introduced coinage into Greece. We are assured
that the native bronze coin of China, the tsien or cash, bearing the inscription tung-p'an, i.e., current money, had its origin about 1120 B.C., at the beginning of the Chan dynasty. The original coins of Asia Minor were of gold or electrum (a mixture of gold and silver), and those of Greece of silver; while in Rome for nearly 500 years after its foundation no metal was coined but copper or brass. The as, a, or libra, a pound weight of copper or brass, was stamped by the state in the reign of Servius Tullius (578–534 B.C.). This coin, the unit of Roman money, was originally oblong like a brick, but subsequently was made round, and was cast, not struck. Before this reign they used for money unstamped bars of copper. According to Pliny, silver was first coined at Rome in 269 B.C.; the principal coin being the denarius; and gold in 207, although it is believed that the latter did not form a part of the ordinary and regular currency of the country until the time of Julius Cæsar, about 49. The emperors possessed the privilege of coining gold and silver, but copper could only be coined ex senatus consulto.—At the date of the invasion of Britain by Cæsar, 55 B.C., the ancient Britons had money of brass and iron, and it was paid by weight. During the reign of Augustus, Cn. nonbelin, one of the native kings, had established his mint at Camulodunum (Colchester), where he caused to be coined money of gold, silver, and brass. Under the emperor Claudius the coinage of the Romans took the place of that of the natives, and circulated until after the abandonment of the country by the conquerors in the 5th century. The earliest coins of England subsequently issued are supposed to be the pennes of Ethelbert, king of Kent (560–616). These were coarsely stamped with the king's image on one side and either the name of the mint master or the city in which they were coined on the other. At this time all money accounts began to be expressed in pounds, shillings, pence, and farthings, or mancusas, although there was no coin but the penny, all other denominations being mere money of account; 30 pence made a manca, 5 pence a shilling, and 40 shillings a pound. The mancas were reckoned both in gold and silver. In King Canute's laws the distinction is made that a manecus was as much as a mark of silver, while a manca was a square piece of gold valued at 30 pence. King Ethelstan (930) de creed that money should be uniform and only coined in towns, and this decree mentions the fact that the clergy shared with the king the privilege of coinage. The Norman kings continued the practice of coining only pence, which were of silver, and with a cross so deeply impressed that they might easily be broken into halfpence and farthings. The date of the earliest use of the word sterling to denote the standard money of England has given rise to much learned discussion; but it has been well established by the testimony of the chronicler Ordericus Vitalis (1075–1143) that it was used as early as during the reign of William the Conqueror. The etymology of the word is by no means so certain. Henry I. in 1108 attached severe penalties to the counterfeiting of money, and during this reign halfpence were first regularly coined. At the commencement of his reign (1154) Henry II. found the money so much debased and reduced in value from various causes, that he provided for a new coinage, and punished those convicted of tampering with it. In 1222 silver farthings were coined. In 1248 it was found that the money of the realm had been so clipped and otherwise defaced that its real worth bore no fixed proportion to its nominal value. Henry III. therefore ordered that the old coins should be brought to the mint and exchanged for new ones, weight for weight; thus entailing the entire loss, which was very great, upon the then present holders of these coins, which justly caused great complaint. During this reign, in 1257, gold pennies were first coined, which weighed \( \frac{1}{12} \) of a pound tower, and passed for 20d. In 1279 Edward I. caused a new coinage of halfpence and farthings to be made, providing at the same time that the old, which were principally mere fractions cut to suit, should no longer pass current. Twenty years subsequently, and during the same reign, so much trouble and loss were suffered from foreign coins of inferior value, known as "pollards," "crockords," &c., that it was decreed that all importers of such money should be punished by death and the confiscation of their property. All persons having arrived from abroad were to be searched, and those having such money were to be immediately imprisoned. All good foreign money was to be taken forthwith on its arrival to the exchange, and all false English money imported was to be seized. No person was allowed to sell wool, hides, skins, lead, or tin, except for good sterling money, silver stamped at the king's exchange, or for a good and sufficient quantity of merchandise; and no money or bullion was to be taken out of the dominions without a license from the king, under penalty of seizure. Persons going abroad, or coming to England, were to be furnished at Dover with a quantity of money of the country to which they were going, sufficient to pay their expenses. The following year (1300) Edward II. positively prohibited the circulation of any money not of his own coinage. In 1301 he diminished the weight of the pound sterling three pennies, equal to one per cent. This was "a departure from the ancient strict and honorable adherence to the integrity of the national money; and a breach, once begun, was with less scruple enlarged by the succeeding kings." Edward II., having married a daughter of the king of France, gave permission to the French merchants to trade with England, and return with their goods and money, notwithstanding the edicts of preceding monarchs against the exportation of coin and bullion. In the reign
of Edward III. (1355), among the extraordinary means taken to prevent the importation of money of foreign coinage from abroad, may be mentioned that of obliging inkeepers to be sworn to search their guests for the detection of such money. Exchanges were established at Dover, London, Yarmouth, Boston, Kings-
ton, and Hull, for furnishing to travellers going and returning foreign money. This monarch, having by 1344 exhausted his exchequer, and embarrassed himself with debts, in his unsuccessful attempts to conquer France, ordered that in future 266 pennies should be made from the pound sterling. Two years subsequently he increased the number to 270 pennies. In 1394 it was decreed that no silver money should be melted for the manufacture of plate or for any similar purpose. Counterfeiting of English money was frequent and to have been a very common practice in those days; and in 1416 parliament passed an act declaring it treason to counterfeit the money of the kingdom, and providing for the punishment by the judges of importers of base coin. Five years later the currency was in so bad a state that a law was passed by parliament providing that all gold money should be passed only by weight, and that all light and vitiated coins should be taken to the tower to be recollected. In consideration of the loss sustained by the holders, the king remitted the usual charge for coinage. In the reign of Henry VII. (1504) a law was passed against either taking English money into Ireland, or bringing Irish money into England. The following year a trifling number of shilling pieces were coined, being the earliest known to have been made. Under Henry VIII. enactments against the exportation of money, plate, and jewels were again passed; and in this reign (1523) silver farthings were coined for the last time. In the reign of Ed-
ward VI. (1551) the currency reached its worst condition of depreciation, in consequence of a state of confusion and fluctuation, that the seller scarcely ever knew what value they were to receive for their goods, when the king applied active and vigorous measures for correcting the evil by raising the standard. Queen Elizabeth signalized the beginning of her reign by raising the silver coin to a higher standard of purity than had been known since the acce-
sion of Henry VIII. In 1559 she caused to be coined for Ireland shillings, sixpences, and thruppences of a baser kind, and established offices for exchange between the two countries. For many years the tradesmen of London had made and issued leaden tokens, which circula-
ted instead of copper coins. This circulation was to a great extent stopped about the begin-
ing of the 17th century by the government, and the more general use of regular coins gradu-
ally took their place. James I. in 1613 de-
based a portion of the coin, having coins in circulation of two qualities of fineness. In 1627 Charles I. issued a proclamation, saying in effect that the buying, selling, and exchang-
ing of all manner of coins and bullion were prerogatives of the crown, which from that time forth he intended to exercise; he inter-
dicted the goldsmiths from pursuing the busi-
ness in any of its branches, and appointed Lord Holland and his deputies to have "the of-
office of our changes, exchanges, and outchanges whatsoever in England, Wales, and Ireland." In 1632 he granted permission to the East In-
dia company to export to Bengal and India £40,000 in foreign gold bullion; and being desirous of cultivating friendly relations with Philip IV. of Spain, he authorized under cer-
tain restrictions the export of the precious metals to the Spanish Netherlands. According to Davenant, the entire gold and silver coinage of England for 100 years, from 1558 to 1659, was: of gold £2,728,000, and of silver £16,109,476, making in all £19,832,476. By the same authority it is estimated that in the year 1600 the total amount of gold and sil-
ver currency in England did not exceed £24,-000,000, and that in 1711 it did not exceed £12,000,000. In 1676, Charles II. being then on the throne, the money coined during the commonwealth and protectorate was called in and recoined. This amounted to £800,000; and by estimating that coinage at one seventh, and giving an allowance for mon-
ey hoarded, writers of that day put the total currency of the country at £8,000,000. The first copper coinage of England since the con-
quest was in 1672, during this reign. James II. (1685–8) issued coins of tin, and author-
ized those of gun metal and of pewter. The first sovereigns were coined in 1489, under Henry VII.; half, quarter, and eighth so-
vereigns by Henry VIII. in 1544; and the first guinea by Charles II. in 1675.—It may be in-
scriptive here to examine into the circumstances under which Great Britain was led to adopt the gold standard, after for a century having the double standard of both gold and silver. Owing to the over-valuation of silver in France before the commencement of the 18th century, the heavy silver coins rapidly disappeared from circulation in Great Britain, only the light and worn ones remaining, often 25 per cent. below the standard. The evil became so great that it brought on a discussion during the reign of William and Mary, in which the philosopher John Locke and William Lowndes, master of the mint, took decided and antagonistic parts. The result was that the government undertook to recin the entire remaining and worn silver currency, and to make it full weight without raising its value. This only facilitated its export and rendered it more difficult to maintain this part of the circulation, a difficulty which lasted throughout the century, the real value of the coins being so uncertain that the guineas fluctuated in price, as measured by silver, from 21s. 6d. to 30s. It was therefore in 1774 de-
clared that silver should no longer be a tender, except by weight, beyond £25. In the words of Mr. J. R. McCulloch, "from 1717 to 1816,
MONEY

no silver coins of legal weight and purity would remain in circulation, but were either melted down or exported to foreign countries." In 1816 the pound standard of silver was coined into 66a, the relative value with gold being as 1 to 14:287. Silver then became a legal tender for only 40s. and under, and has since only been coined for account of the government itself, at an apparent profit; but as the government maintains the circulation up to the standard, this profit is more nominal than real. By the currency bill of 1819, providing for the resumption of cash payments in 1823, all the old statutes against the melting and exportation of coin or plate were repealed, as well as the oath required that it was not melted plate or coin or clippings of coin. In 1792 the congress of the United States by law fixed the relative value of silver and gold at 1 to 15; and as a consequence, when a foreign balance had to be liquidated, silver being over-valued as compared with European standards, gold was exported, and it was found impossible to maintain a gold circulation. In 1834 the standard was altered to 1 to 16, while with other nations it was generally 1 to 15¾. Now silver was so largely exported that the proportion was on March 3, 1853, altered to 1 to 14:88, and silver was made a legal tender only for sums under $5. By the coinage act of Feb. 12, 1873, it was again changed to 1 to 14:95. After the discovery of gold in California and Australia the economists of Europe predicted a great decline in its value. Prominent among these was M. Chevalier, who in 1859 published a volume entitled De la baisse probable de l'or, which was translated into English by Mr. Richard Cobden. Under the influence of the teachings of the economists, the Netherlands, Belgium, and Germany all demonetized gold and adopted silver as the only legal tender at a fixed rate. In those countries gold only circulated as a commodity, subject to daily fluctuations in value; and as a consequence, deprived as it was of its legal support as money, it was but little used. In 1861 Belgium, "at the urgent request of her commercial and industrial interests, and in defiance of the opinion of the theorists," re-adopted gold as a legal tender. The German empire has now (1874) adopted gold alone as a legal tender, with silver only for subsidiary coinage. Denmark, Sweden, and the Netherlands have decided upon the same course, to be followed, as is believed, by Belgium. In India prior to 1835 gold and silver were both a legal tender, but silver then became the exclusive one. In 1841 the Indian government authorized gold mohares to be received when offered for taxes. In December, 1852, however, this was prohibited for fear that all payments might be made to them in gold, which was the cheaper metal, while they might be obliged to make all payments in silver, which was the only legal tender.—The relative values of silver and gold at different periods have been as follows:

The relative productions of these two metals have varied from about 43 oz. of silver to one of gold in 1800 to about 69 oz. of silver to one of gold in 1823. The following table, derived from the "industances" made with the masters of the mint, exhibits the number of pounds, shillings, and pence which have at various times in England been coined out of a pound of silver, with the standard of fineness:

The last named proportions continued down to 1816 (56 George III.), and the standard of fineness is still the same, but the weight of the coins has been reduced, the shilling weighing but 87½ grains, and a pound of silver thus producing 66½ shillings.—Early in the latter half of the 17th century the public mind of England became deeply interested in projects for the establishment of institutions of credit which should economize the use and add to the power of the then limited metallic circulation of the realm. They had seen and appreciated how in Amsterdam the ownership of coins, and in Venice the ownership of these as well as of claims upon the state, were made to furnish the means for the adjustment of debts even more efficiently than the coins themselves, which were at the same time protected from clipping, sweating, wear, and tear; and how the bank of Genoa had even advanced beyond this, by furnishing its own notes for circulation. Indeed, they had noticed the success of the goldsmiths and other private bankers in issuing their own promissory notes, payable to the bearer on demand, as well as bonds or sealed bills bearing interest and payable at a fixed day at currency. In 1657 Samuel Lambe, a well known merchant of London, published a pamphlet entitled "Trade, Shipping, Banks," in which he took the ground that it was desirable to establish banks; "for no nation," he says, "yet made use of them, but they flourished and thrived
MONEY

exceedingly; they will, by well ordering of them, bring back the gold and silver drained out of this land by the Hollanders’ banks,” ¾ c.
The result of this discussion, which was continued for years, was the establishment of the bank of England in the year 1694. This institution, at once on commencing business, issued its notes payable without indorsement to the bearer on demand. Prior to this time bank notes, properly speaking, with an extended circulation without indorsement, were unknown in Europe, unless those issued in 1658 by the bank established by Palmstruck in Stockholm were of this character. The bank of England was the first in the world which agreed to issue its notes, payable on demand, in exchange for individual paper, payable at a future date.

“The bank thus undertook,” in the words of Stephen Colwell, “to perform an impossibility, in the hope that it would not be called upon to redeem the promise or make the attempt;” and he adds: “What the bank could do was to give its own notes of convenient denominations for circulation in exchange for individual paper, and payable at the same time as it; and in doing this alone the bank could have rendered a great service to the public with small risk.” The same writer regards this step of the bank as “a Pandora’s box of evils opened to trouble the commercial world,” and to be the main cause of the unpopularity of banks even unto the present hour, by reason of their irregular action and instability.—In America, “the several provinces in their infancy,” says Wright, the author of “The American Negotiator” (London, 1767), “had but little trade, and consequently little money. The tools, utensils, and necessaries for planting they were at first supplied with from Britain, involved them in debt before they were able to raise goods for exportation to pay their creditors; and the goods they first raised were often so ordinary in quality or so little in quantity that they were able to export to a foreign market, that the net proceeds of the same often turned out poorly; by which means the planters remained continually in debt to the British merchants, and occasioned the balance of trade to be always against them; and having neither goods nor cash sufficient to remit to their creditors, the consequence has been that many bad debts have been made and great losses sustained, as the merchants of Great Britain have but too painfully experienced.” As the northern colonies improved in their condition, the British merchants received their claims in part; but this “prevented the cash staying with them” (the colonists), “and obliged them to ship it off with their other merchandise toward paying their debts.” The consequences, as already shown, were that the colonists were forced to use their money wampum, musket balls, beaver skins, tobacco, corn and beans, and in fact to resort to a general barter. About the middle of the 17th century the trade with the West Indies brought into Massachusetts a con-

The currency of Rhode Island suffered such a depreciation between 1744 and 1759, that while in the former year it required £450 to obtain £100 sterling, in the latter it required £2,300. However, in or about the year 1767, measures were taken to place the currency of some of the colonies on a better footing. The following were then the rates of sterling exchange in the provinces named: Massachusetts, 1731; New York and East Jersey, 1735; Pennsylvania and West Jersey, 165 to 169; Virginia, 125; Maryland, 145; North Carolina, 145; South Carolina, 700; Georgia, 100; Jamaica, 140; Barbadoes, 135; Nevis and Montserrat, 175; Antigua and St. Christopher, 165.

—The continental congress as originally constituted was as feeble a government as any that
can be imagined. It had no executive head and no finance minister. It was expected to and did prosecute a war against one of the most powerful nations then existing, while it had no means whatsoever of levying taxes through any officials of its own. It might only recommend to the several colonies or states to levy and collect certain taxes for its use, but it had no means for enforcing the payment of them. It however fully exercised the power to issue and borrow money, and on May 10, 1775, resolved to issue $500,000 of bills of credit, for the redemption of which the faith of the colonies was pledged; a quota was apportioned to each colony, which was liable for the discharge of its proportion. The united colonies were however liable for any part not discharged by any colony. Legal-tender acts of the most stringent character were adopted by congress and the colonies, and subsequently by the states. No taxes were even recommended by congress to be levied until Jan. 14, 1777; but the resolution then passed was so indefinite, no quotas being named in it, that it had little or no result. By resolution of Nov. 22, 1777, the states were recommended to raise $5,000,000, with quotas annexed; but this had very little effect, small sums only being raised and paid by some of them within the year 1778, and by others subsequently. In an address to the people, May 8, 1778, congress said: "What are the reasons of your money being depreciated? Because no taxes have been imposed to carry on the war." In 1779 immense sums were called for, for that year and for 1780—$186,000,000 for the latter year alone: but small was the actual amount received. Before any depreciation of bills took place $9,000,000 had been issued; but in March, 1778, $1 in coin was worth $1 75 in paper; in March, 1779, $10; and in February, 1780, $40. At this latter date $200,- 000,000 had been issued, and was estimated to be worth but $5,000,000 in coin. By the end of this year the final redemption of the bills came to be doubted, and the depreciation had reached 100 for one; by May, 1781, it was from 200 to 300 for one, and at or about this latter date they ceased to circulate as money at all. On June 2, 1781, the assembly of Penn- sylvania, on the recommendation of congress, repealed all tender acts; and the same was done about the same date by all the states. The total amount of continental money issued was officially stated on Jan. 30, 1828, by Joseph Nourse, register of the treasury, at $241,552,780, and by Thomas Jefferson it has been estimated at $200,000,000. Early in 1780 it was stated that specie “was never more plenty or more easily collected than at that time," the plentiful supply being occasioned by the large sums coming from the expenditures of the British army in New York and of the French army and navy, and from imports from Havana. In December, 1780, Peletiah Webster, a very careful writer on finance in Philadelphia, esti- mated the total amount of specie in the thirteen states at from $10,000,000 to $12,000,000. Large as this was then considered to be, it was not more than about the then annual expendi- tures of the government estimated in coin. This will at once and readily give an idea of the stupendous work which was undertaken by this feeble government of a poor and scattered people, and go far toward explaining the total collapse of its finances, conducted without any power of taxation, and until 1781 without sys- tem or a head. During the war the several colonies and states also issued paper money of their own, to an estimated aggregate amount between 1775 and 1788 of $209,524,776. By resolution of Feb. 2, 1781, congress created the office of superintendent of the finances, to which on the 20th of the same month Robert Morris was appointed. On May 17 he submitted a plan for a bank, and on the 26th congress passed a resolution approving the plan, and pledging itself for its promotion, under the name of "The President, Directors, and Com- pany of the Bank of North America," and on Dec. 31 it passed "an ordinance to incorporate the subscribers to the bank of North America." The capital was $400,000, of which $254,000 was subscribed by the government. This in- stitution proved to be of very material assistance to the national finances. The first congress under the constitution in 1789 passed an act imposing duties on imports, by which the pound sterling was valued at $4 44. There was at the time no United States coin of the denomi- nation of the dollar, but this was merely the money of account based upon the Spanish dol- lar, which had long been in use in the country. Coins from all parts of the world were taken at the custom house at a statutory value. On April 2, 1792, congress passed a law organizing the mint, but permitting the circulation of foreign coins for three years, by which time it was believed the new coinage would be ready in suffi- cient amount. (For the provisions of this, and of prior and subsequent congressional acts re- lating to coinage, see Corrs.) In 1791, on the recommendation of Alexander Hamilton, then secretary of the treasury, the first bank of the United States was established, and remained in existence until the expiration of its charter, March 4, 1811. During the war of 1812-15 with Great Britain the government experienced great embarrassment in its finances, and by August, 1814, found it impossible to negotiate any further loans. In 1812 treasury notes having one year to run and bearing 5 per cent. interest, were issued to the amount of $3,000,000; in 1813, $6,000,000; and in 1814, $8,000,000. These were not a legal tender, but were receivable in payment of duties on imports and other taxes due to the general government. In October, 1814, when Alex- ander J. Dallas became secretary of the treas-ury, these notes were in such ill repute that, in the words of a historian of that period, "none but incessant creditors or contractors
in distress, or commissaries, quartermasters, navy agents, acting as it were officially, seemed willing to accept them." Indeed, they were at a heavy discount compared with bank notes, which were not redeemable in coin; but by Jan. 10, 1815, they sold at par. The government has repeatedly since been obliged to issue treasury notes bearing interest and payable at a fixed period after date, but not a legal tender, and not generally used as currency. On April 8, 1816, a bill for the incorporation of the second bank of the United States was passed, and this institution remained in existence until the expiration of its charter in 1836. From the inauguration of the present government under the constitution, March 4, 1789, until the civil war, 1861-5, with the exception of the circulation of the two banks of the United States, the treasury notes already mentioned, and the banks of the District of Columbia, the paper money of the country was generally furnished by banks chartered by the several states. The commencement of the secession movement in November, 1860, soon caused a financial crisis and a total paralysis of business, under the effects of which the revenues of the government rapidly declined; and by Dec. 17 it became necessary to pass a law for the issue of $10,000,000 one-year treasury notes bearing 6 and 12 per cent. interest, and which were authorized to be paid to the public creditors. By act of March 2, 1861, $22,465,000 two-year and $12,896,350 sixty-day notes were provided for; and by acts of July 17 and Aug. 5, 1861, $133,999,750 three-year 7-30 notes, and $50,000,000 treasury notes payable on demand, the latter being by act of Feb. 12, 1862, to meet a most pressing emergency, increased by $10,000,000. The preparations for war from March 4, 1861, and its subsequent prosecution, called for immense expenditures; and by December, 1861, the secretary of the treasury had borrowed from the banks and capitalists of New York, Philadelphia, and Boston $144,000,000, which he had paid for the interest payable in coin, and in the course of this month these banks found themselves under the necessity of suspending specie payments. The demand treasury notes, not being a legal tender, did not enter freely into circulation, and there were instances of soldiers having to submit to the loss of a discount on those received for pay of from 4 to 20 per cent. in the District of Columbia. These notes were kept at par with the banks and received by them so long as they had to pay the government for loans; but by Feb. 5, 1862, the last of these loans was paid for, and the banks refused to receive the notes. The treasury was by this time nearly empty, and the secretary was unable to negotiate any further loans, while there were the most pressing demands upon him. The floating liabilities then due were $160,000,000, and not less than $150,000,000 more would be wanted before July 1 following. The committee of ways and means of the house of representatives had about this time perfected a bill for the issue of $150,000,000 in notes, to be a legal tender for the payment of all debts, public and private. The secretary early in February strenuously urged the passage of this act, to the support of which he had however come with great reluctance. He said: "Immediate action is of great importance. The treasury is nearly empty. I have been obliged to draw for the last installment of the November loan; so soon as it is paid, I fear the banks generally will refuse to receive United States notes. You will see the necessity of urging it through without more delay." It passed the house of representatives Feb. 6, 1862, and the senate with important amendments on the 18th; and after being referred to a conference committee, it was passed in an amended form by the house on the 24th and by the senate on the 25th. The same day it received the signature of the president and became a law. These notes were made receivable in payment of all taxes, internal duties, excises, debts, and demands of any kind due to the United States, except duties on imports, and of all claims and demands against the United States of any kind whatsoever, except for interest upon bonds and notes, which shall be paid in coin; and shall also be lawful money and a legal tender in payment of all debts, public and private, within the United States, except duties on imports and interest aforesaid." They were also receivable "the same as coin at the par value, in payment for any loans that may be hereafter sold or negotiated." By act of July 11, 1862, $150,000,000 more of these notes were authorized, $50,000,000 to be held as a reserve for the payment of temporary loans. In all, by these acts and those of Jan. 17 and March 3, 1863, $450,000,000 were authorized, and $400,019,206 were actually issued, besides compound interest and 7-30 notes. In addition to these, $50,000,000 of fractional currency was authorized, of which $48,151,000 had been issued to Nov. 1, 1874. Subsequent to the close of the war, in addition to other notes, $44,000,000 of the legal-tender notes were retired, thus reducing their amount to $356,000,000; while by act of June 22, 1874, the volume of these notes was fixed at $382,000,000, which amount had been issued on Nov. 1, 1874. By act of congress approved Feb. 28, 1863, the national banking system was established. Under this system, to Nov. 1, 1874, circulation had been issued and was then outstanding to the amount of $551,997,246. Under act approved July 12, 1870, providing for banks whose issues should be redeemable in gold on demand, $2,150,000 of notes have been issued. In 1873 the director of the mint estimated, from the most trustworthy data, the gold coin in the country at $135,000,000, and the subsidiary silver coin at $5,000,000, total $140,000,000; thus making the grand total of money of all kinds $394,288,246. A careful estimate of the circulating medium of the United Kingdom of Great
Britain and Ireland at the close of 1872 placed the gold coin at £105,000,000, the silver coin at £15,000,000, and the bronze coin at £1,148,000; total metallic circulation, £121,148,000. The circulation of the bank of England on Oct. 16, 1872, was £34,328,708. The notes in circulation in the United Kingdom, other than those of the bank of England, in September, 1872, were as follows: England, £5,057,910; Scotland, £5,313,560; Ireland, £7,342,081; making a total paper circulation of £51,942,259, and of metal and paper combined of £179,090,259 = £241,218,568. According to Necker, the circulation of France in 1789 was equivalent to $450,000,000, all metallic. The assignats issued by the revolutionary government of France during the years 1790–96 are estimated as high as $9,000,000,000. The circulation of France at the present time is estimated at 4,000,000,000 francs metallic, while the notes of the bank of France in circulation Oct. 9, 1874, were 2,970,881,660 francs; total, 6,970,881,660 francs = $1,394,176,532.—Money of Account. A full and clear understanding of money can hardly be had without a realization of the true position of money, and the office of money of account; a subject so important, and even adverted to in any of the treatises upon money. When any coin or weight of gold or silver, or any other article of value or of general acceptability, has for a considerable time been used as an equivalent or in payment for things purchased, the people using it assumes the value of the article in question as the unit of a money of account, and employ it to express prices. By incessant use it is impressed upon and becomes familiar to the mind, is "committed to the memories of a whole nation," and "performs the same office with regard to the value of things that degrees, minutes, seconds, &c., do with regard to angles, or as scales do to geographical maps, or to plans of any kind." It becomes in fact "an arbitrary scale of equal parts, invented for measuring the respective values of things vendable." The use of a money of account is in no respect a mechanical process by which other articles are compared by weight or bulk with gold or silver; but it is an arithmetical one, by which they are compared with a unit of value, which has had its origin in some coin or other commodity which possesses the quality of acceptability for the payment of debts and the purchase of commodities. Hence it is that a money of account, having been long in use, and become a part of the modes of thought of a people, often long survives the existence of the coin or other commodity upon which it was based. The money of account of the bank of Venice, undisturbed for 500 years, had no coins to correspond with it, and the value of all coins was expressed in it. A money of account is a language in which all values or prices may be expressed, and by means of which the relative values of commodities may be stated. It is something which each and every one carries in his mind, as he does his knowledge of words or of arithmetic, and in so doing he is quite independent of any thought of coinage or of circulating notes. These are facts which have in whole or in part been recognized by various writers differing in almost all other respects in regard to money, and they have been controverted by but few. But being facts close at hand, familiar, and almost self-evidently true, their full significance and far-reaching importance have been overlooked and disregarded by almost all economists. Count Garnier and Stephen Colwell have of all writers probably most fully appreciated the importance of a clear understanding of money of account. According to the latter, it is the central point from which the whole science of money must be studied, and without which mode of procedure no true conception of it can be had. The money of account in use by a people is not only the standard by the aid of which the value of commodities may be stated, but is used to express the value of coins or circulating notes, and, if these coins or notes be of the same denomination as the money of account, unerringly indicates whether such coins or notes are at par, at a discount, or at a premium. Had men better understood this subject in Great Britain during the suspension of the bank of England, 1797–1823, there would have been far less discussion than there was as to whether bank of England notes were then at a discount or gold was at a premium. The bullion committee had a glimmering of the truth when they "doubted whether, since the new system of bank of England payments has been fully established, gold has in truth continued to be our measure of value." The money of account had in fact assumed itself to the standard of payment furnished by the bank, and the committee half suspected that such was the case.—Theory of Money. In its theoretic or economic aspects, money presents a field of apparently hopeless discord, controversy, and confusion, without a single doctrine established as a principle of universal or even of general acceptance. In a word, no one of these doctrines can be presented as a truth which needs only to be stated, not demonstrated; no one who writes upon them can properly lay down any so-called principles without at the same time giving the ground upon which each one of them claims to rest. To go no further back, Montesquieu and Hume about the middle of the 18th century laid down the dictum which, stated in the words of Hume, is as follows: "It seems a maxim almost self-evident, that the prices of everything depend on the proportion between commodities and money, and that any considerable alteration on either has the same effect of heightening or lowering the price;" and from that time to the present hour there has been a sharp and never ceasing controversy upon every phase of the subject. A memorable era in this controversy was the period between the suspension
of specie payment by the bank of England, Feb. 27, 1797, and the decade following re-
sumption in 1823, which gave rise to discus-
sions which, in the opinion of Mr. J. B. McCul-
loch, "all but perfected the theory of money." A particularly striking feature in the literature of the discussions of that time is that which is known as the "Bullion Report," i.e., the report from the select committee appointed to inquire into the cause of the high prices of gold bullion, and to take into consideration the state of the circulating medium and the exchanges between Great Britain and foreign parts. This report was ordered by the house of commons to be printed June 8, 1810. The conclusions of the committee were, "that there is at present an excess in the paper circulation of this country, of which the most unequivocal symptom is the very high price of bullion, and next to that the low [high according to the American mode of expression] state of the continental exchange; that this is to be as-
cribed to the want of a sufficient check and control in the issues of paper from the bank of England, and originally to the suspension of cash payments, which removed the natural control. For upon a general view of the sub-
ject your committee are of opinion that no safe, certain, and constantly adequate provision against an excess of paper currency, either occasional or permanent, can be found except in the convertibility of such paper into specie." The committee "doubted whether, since the new system of bank of England payments has been fully established, gold has in truth con-
tinued to be our measure of value, and wheth-
er we have any other standard of prices than that circulating medium issued primarily by the bank of England, and in a secondary man-
er by the country banks, the variations of which in relative value may be as indefinite as the possible excess of that circulating me-
dium;" and thought that "an increase in the quantity of the local currency of a particular country will raise prices in that country, exactly in the same manner as an increase in the gen-
eral supply of precious metals raises prices all over the world." Briefly, the report was, and probably is still, the most carefully elabora-
ted and consistent statement of the doctrines of Montesquieu and Hume to be found in the language. It was far, however, from setting the subject at rest. There was then a large school, and there is now perhaps a larger one, which argues against all the conclusions of the committee, as well as against the reasoning by which those conclusions are reached. It has been controverted by this latter school that money has a fructifying influence upon industry, and that an increase in its volume may increase production, trade, and commerce, and, so far from necessarily increasing prices, in some cases actually reduce them; that if the theory were true, no increased production in a coun-
try, were it two, five, ten, or twenty fold, without a corresponding increase in the vol-
ume of money, could increase the aggregate value of these productions a single dollar. There are those who contend, in opposition to the bullion report, that "money should be a thing of a country, of a people, and not of the world;" and that the financial and business affairs of a country should in no wise be based upon the precious metals, which are, it is con-
tended, liable to export, beyond the control of the people or the authorities of a state. There have long been a considerable number of writ-
ers in Great Britain holding these opinions, but it is in this country and we will introduce a re-
atively recent period that such views have taken most decided and original shape. By no means all of these writers contend for an arbitrary volume of such money, only limited by the wants of the state or of the people at a particular time. Several of their plans have contemplated the conversion of this money by means of funding to any extent which a curt-
tailment in the monetary wants of the people may demand. Probably the earliest advocates of such a system as is here referred to was Ed-
ward Kellogg, who in September, 1843, pub-
lished in New York a pamphlet entitled "Cur-
reny, the Evil and the Remedy." He proposed as a remedy for usury, that the United States government should establish a national safety fund, which should lend money on mortgage of real estate at 3 per cent. per annum, in the form of "circulating medium or safety fund notes," which notes were to be payable or fundable at the pleasure of the holder in "treas-
ury notes" or bonds, bearing interest at the rate of 2 per cent. per annum, and payable on and after one year from a given day, in cir-
culating medium or safety fund notes. This idea was elaborated by him in subsequent works; and immediately before and after the passage of the act of Feb. 23, 1862, providing for the issue of United States legal-tender notes, it was strongly urged upon the govern-
ment by prominent financiers that these notes should be made interconvertible at the plea-
sure of the holder with United States bonds. This scheme of finance, called the "$565 bond plan," has attracted much attention. Its friends maintain that the interchangeability of national paper money with government bonds bearing a fixed rate of interest will give an automatic, self-adjusting volume of currency at all times, commensurate with the wants of the people and of business; and that it will preclude the possibility of financial crises by introducing a cash system of business instead of the credit one which at present exists. In entire consist-
tency with the history of all financial schemes and theories, old as well as new, this plan is opposed with a vigor nearly if not quite equal to that with which it is advocated.

MONGE, Gaspard, a French mathematician, born in Beaune in 1746, died July 28, 1818. He became assistant to Bossut, and also to the abbe Nollet at Mèzières, whom he succeeded in the chair of natural philosophy. He made nu-
umerous experiments in physics and chemistry, and investigations into the principles of geometry, which led to the foundation of a new and important department of that science, to which he gave the name of descriptive geometry. In 1780 he was made a member of the academy of sciences, and soon after assistant professor of hydrodynamics in Paris. During the revolution he was for a short time minister of marine. Through his exertions the normal and polytechnic schools were established, and he taught in both. He accompanied the army into Italy and Egypt, and on his return was made president of the Egyptian commission, head of the polytechnic school, and member of the senate with the title of count of Pelusium; but on the fall of Napoleon he was deprived of all his honors. He was the first who applied the differential calculus to the general theory of surfaces. His best known work is the Géométrie descriptive (1799; 4th ed., 1819).

**Monghir**, a town of British India, in Bengal, on the right bank of the Ganges, 80 m. E. S. E. of Patna; pop. about 30,000. The numerous temples give it a fine appearance, and the picturesque and salubrious situation make it a favorite residence for invalids. It contains 16 markets, extending 1½ m. from N. to S. Inferior hardware and firearms are manufactured. The houses are mostly of the poorest description. A rock jutting into the river is a shrine for pilgrims, and adjoining the bathing place was formerly a temple which has been converted into a mosque. The town is of great antiquity, and formerly contained a magnificent palace. The fort, celebrated for its picturesqueness, is built on a prominent rock; it is 4,000 ft. long and 3,500 ft. wide, and contains the official and European residences. It was once an important stronghold, but has declined in importance, and is falling to ruins.

**Mongolia**, a country of Asia, part of the Chinese empire, lying between lat. 37° and 54° N., and about lon. 85° and 125° E., bounded N. by Siberia, N. E. and E. by Manchuria, S. by the Chinese province of Chihli, Shansi, Shensi, and Kansu, and W. by East Turkestan and Dzungaria; area, about 1,300,000 sq. m.; pop. about 2,500,000, of whom 500,000 are Chinese. It is chiefly a plain, about 3,000 ft. above the sea, almost destitute of wood and water. In the central part the great sandy desert of Gobi stretches N. E. and S. W., occupying about a third of the entire area. The chief mountain ranges are the Altai and its subordinate chains, which extend eastward, under the names of Tangma-Oola and Kenthal, as far as the Amoor; and the Ala-shan, In-shan, and Khingan ranges, which commence about lat. 38° and lon. 107°, and run N. E. and N. to the Amoor, crossing into Manchuria. The rivers are chiefly in the north, the Selenga, Orkhon, and Toledo unite and flow into Lake Baikal. The Kerulen and Onon rise near each other on opposite sides of the Kenthal range, and flow N. E. to the Amoor. In the south, the coun-

try S. of the In-shan range is traversed by the Hoang-ho or Yellow river. In the N. W. part of the country lakes abound, the largest of which are the Uspa-nor, the Kossogol, and the Iko-aral.—Mongolia is divided into four principal regions: 1, Inner Mongolia, between the great wall and the desert of Gobi; 2, Outer Mongolia, between the desert and the Altai mountains, reaching from the Inner Khingan to the Thian-shan; 3, the country W. of the Ala-shan; 4, Ulissutai and its dependencies. Inner Mongolia is divided into 6 corps and 24 tribes, which are subdivided into 40 standards, each comprising about 2,000 families commanded by hereditary princes. The Kortchin (about 200,000) and the Ortoos (400,000) are the principal tribes. Another large tribe, the Tzakhars (180,000), occupy the region immediately north of the great wall. Outer Mongolia is divided into four circles, each of which is governed by a khan or prince who claims descent from Genghis Khan. The Khalkas (250,000) are the principal tribe, and their four khanates are divided into 86 standards, each of which is restricted to a particular territory. The country W. of the Ala-shan is occupied by Torgots, Khostos (120,000), Khalkas, and other tribes, arranged under 29 standards. Ulissutai is a town of 2,000 houses in the W. part of Mongolia, and lies in a well cultivated valley. Its dependent territories comprise 11 tribes of Khalkas divided into 31 standards.—Mongolia is supposed to be rich in metals and minerals. Its immense plains and forests are inhabited by multitudes of wild animals, among which are the elk, the stag, the wild goat, the wild ass, the yak, the brown and black bear, the ounce, and two species of the black-furred hares, squirrels, and foxes. The wolves of Mongolia are large and fierce; they will pass through a flock of sheep to attack the shepherd. Among the birds are pheasants and eagles. The eagle is very common, and makes its nest where it pleases, the people never molesting it. The double-humped or Bactrian camel exists in both the wild and domesticated state, supplying excellent milk and large quantities of butter and cheese.—The soil of Mongolia is poor, and little of it is fit for cultivation on account of the want of moisture, neither rain nor snow falling in sufficient quantities to exceed the activities of the mountain ranges. From the great elevation of the country and the dryness of the atmosphere, the climate is excessively cold. Mercury in some parts often remains frozen for weeks in succession. The winter lasts nine months, and is immediately succeeded by summer, in which there are sometimes days of stifling heat. The nights are almost invariably cool. At all seasons the weather is subject to great and sudden changes. In the southern part of the country, where Chinese immigrants have introduced agriculture, the temperature has risen with the increase of cultivation, so that kinds of grain which formerly would not
ripen because of the cold are now raised with success. In this part of Mongolia villages are frequent, and a portion of the native race have adopted a settled life. The greater part of the Mongols, however, are gradually retiring toward the north, and the Chinese population is rapidly taking their place.—The Mongols belong to the so-called Turanian, Mongolian, or Uralo-Altaic division of mankind. Their branch, best designated as that of the Mongols proper, is composed of three families, of which the East Mongols are the inhabitants of the present territory of Mongolia; these are sub-divided into Shara Mongols, occupying the southern portion, and the Khalka Mongols, living in the north. The West Mongols, comprising Calmucks, Torgots, and others, were driven out of their land at the time of Genghis Khan, and a portion of them now lead a nomadic life in the steppes between the Volga and the Ural, while the others dwell on the slopes of the Altai mountains, and are generally known as Black Calmucks. On the Chinese frontier, in the region of the Lena, and from the Onon as far as the Oka, is found the third family, called Burjats. Some Mongols proper, still speaking a Mongolian dialect, inhabit the northern portion of Iran, where they are known as Aimaks or Hazarehs. Though the name of Tartars is generally applied also to Mongols proper, there can be no doubt that the Tartars form a distinct branch of the Mongolian or Turanian division. (See TURKISH RACES AND LANGUAGES.) The present inhabitants of Mongolia are generally stout, squat, swarthv, and ugly, with high and broad shoulders, pointed and prominent chins, long teeth distant from each other, eyes black, elliptical, and unsteady, thick, short necks, bony and nervous hands, and short muscular arms. Their stature is equal to that of Europeans. They are, with few exceptions, nomadic, living in tents and subsisting on animal food. The Mongol tent for about 3 ft. from the ground is cylindrical; it then becomes conical. The portion made of wood is a trelliswork of crossed bars which may be folded up or expanded. Above these, a circle of poles fixed in the trelliswork meets at the top, like the ribs of an umbrella. Over the woodwork is stretched a thick covering of coarse felt. The door is low and narrow. At the top of the tent is an opening to let out smoke, which can be closed by a piece of felt hanging above it, to which is attached a long string. The interior is divided into two compartments, that on the left being for the men, while that on the right is occupied by the women and is also used as a kitchen, the utensils of which consist chiefly of large earthen vessels for holding water, wooden pails for milk, and a large bell-shaped iron kettle. A small sofa or couch, a small square press or chest of drawers, and a number of goats' horns fixed in the woodwork, on which hang various utensils, arms, and other articles, complete the furniture. Household and family cares are assigned entire-ly to the women. The men conduct the flocks and herds to pasture. They sometimes hunt wild animals for food or for their skins, but never for pleasure. When not on horseback, the men pass their time in absolute idleness, sleeping all night and squatting all day in their tents, drinking tea or smoking. The only persons who learn to read are the lamas or priests, who are also the painters, sculptors, architects, and physicians of the nation. The Mongol is so accustomed to horseback that when he sets foot on the ground his step is heavy and awkward, his legs bowed, his chest bent forward. The Mongols marry very early, and their marriages are regulated entirely by their parents. A plurality of wives is permitted, but the first wife is always the mistress of the household. Divorce is very frequent. The husband who wishes to repudiate his wife sends her back to her parents, without any formality except a message that he does not require her any longer. This does not give offence, as the family of the lady retains the cattle, horses, and other property given to them at the time of the marriage, and have an opportunity of selling her to a fresh purchaser. The women come and go at pleasure, ride out on horseback, and visit freely from tent to tent. The chiefs of the Mongol tribes and all their blood relatives form an aristocracy who hold the common people in a mild species of patriarchal servitude. There is no distinction of manners or of mode of living between these classes; and though the common people are not allowed to own land, they frequently accumulate considerable property in herds and flocks. Those who become lamas are entirely free.—The ancient religion of the Mongols was a species of Shamanism, but in the 13th century they embraced Lamaism. Their religious system at the present day is similar to that of Thibet, and they acknowledge the spiritual supremacy of the grand lama at Lassa. (See LAMAISM.) Mongolia abounds in well endowed lamaseries constructed of brick and stone, with elegance and ornamentation. The most famous is that of Urga or the Great Kooren, on the bank of the river Tola, in the country of the Khalkas. Thousands of lamas dwell in this lamasery, and the plain adjoining it is always covered with the tents of pilgrims. In these lamaseries a strict monastic discipline is maintained, but each lama is at liberty to acquire property by any occupation not inconsistent with his priestly character. Nearly all young men of the free Mongols are devoted from infancy to the priesthood. Almost every lamasery of the first class has a living Buddha, who like the grand lama of Thibet is worshipped as an incarnation of the deity. The influence of these personages is very great, and the Chinese emperors spare no pains to win over to their interest those who manage these deities.—The trade between China and Russia passes through Mongolia at Kajhita, a town on
the borders of the two countries. This trade, which is entirely under the supervision of Manchuchoo officers, introduces among the Mongols European goods in moderate quantities. — The Mongolian language was reduced to writing about the 14th century. Its literature consists in great part of translations of Chinese books, but it embraces a few original histories and many poems, relating chiefly to Genghis Khan and to Tamerlane. The history of the Mongols properly commences with Genghis Khan. At his birth (about 1160) the Mongols were divided into petty and discordant tribes. He united them into one nation, and led them forth to conquer the world. Under his banners they subjugated the whole of Tartary, and a great part of China, Corea, Afghanistan, Persia, and Russia. Under his sons and successors the conquest of China was continued, the caliphate of Bagdad was overthrown, the sultan of Iconium in Asia Minor made tributary, and Europe overrun and devastated as far as the Oder and the Danube. The Mongol empire was at this time the most extensive that the world has ever seen. Kublai Khan, the grandson of Genghis, established the first Mongol dynasty in China (1279-1368), and conquered also Cochín-China and Tonquin. He is known in Chinese history as the emperor She-tsu, and as the founder of the 24th or Yuen dynasty. In 1368 the native race rose in insurrection and established their independence under the Ming dynasty. The Mongol empire was split into several independent sovereignties in the 18th century, but was reunited by Tamerlane in the 14th. After his death (1405) the Mongol power slowly declined, and in the early part of the 17th century the Mongols gradually submitted to the sovereignty of the Manchuchoo emperors of China. But they yield little more than a nominal obedience. The Chinese government watches and humors them with incessant anxiety, and conciliates their chiefs by annual presents of considerable value. The Mongol empire in India, however, established by Tamerlane's descendant Baber in 1526, lasted nominally till 1858. (See Moguls.) — See Huc's "Travels in Tartary, Thibet, and China" (2 vols., 1852), and Wolff's "Geschichte der Mongolen" (Breslau, 1872).

MONGOUS. See Ichneumon, and Lemur.

MONITEAU, a central county of Missouri, bounded N. E. by the Missouri river, and drained by Saline, Moreau, and Moniteau creeks; area, 400 sq. m.; pop. in 1870, 11,375, of whom 879 were colored. Iron, limestone, and excellent coal are found, and the soil is generally fertile. The county is traversed by the Pacific railroad of Missouri. The chief productions in 1870 were 204,589 bushels of wheat, 608,917 of Indian corn, 204,036 of oats, 82,274 of potatoes, 53,706 lbs. of tobacco, 42,658 of wool, 178,283 of butter, and 6,025 tons of hay. There were 5,004 horses, 1,514 mules and asses, 10,727 cattle, 17,187 sheep, and 23,271 swine. Capital, California.

MONITOR, the common name of many of the old-world slender-tongued lizards of the family Uromidae and genus Varanus (Merr.). They have an elongated head; long, extensible, bifid, fleshy tongue, enclosed in a sheath at the base; no teeth on the palate, those of the jaws flattened at the roots, lodged in a common groove or alveolus without internal border, with the crowns generally pointed and curved backward; the neck long; the head and body covered with tuberculated non-imbricated scales; the tail very long, sometimes containing 80 vertebrae, capable of reproduction, non-prrenchisic, compressed and keeled or rounded according as the species are aquatic or terrestrial; no femoral pores nor dorsal crest; eyes with two distinct movable lids; feet large, with five unequal, non-palmed toes, furnished with strong claws; in the fore limbs the first finger is the shortest, and the third and fourth longest; in the posterior the fourth is three times as long as the first. The monitors form a natural transition to the serpents, in the suspension of the bones of the face to the cranium and their mobility, in the incomplete circle of the orbits, in the long and narrow lower jaw loosely united in the middle, in the tongue, and in the scaly covering. The colors vary from black to deep green, with lighter spots arranged in various ways so as to resemble mosaic work; many of these patterns are so admirable that the skin has been used to cover jewel boxes. These reptiles are, next to the crocodiles, the largest of living saurians; they live either in the neighborhood of rivers, or in dry sandy regions, the former class being said to give notice of the presence of crocodiles by a whistling sound, whence their common name;
reptiles, and lizards, small tortoises, fish, and mammals. The true monitors, of which fewer than 20 species are described, are confined to Asia, Africa, and Australasia. Of the genus *Varanus*, erroneously called *tupinambis* by Daudin, the best known aquatic species is the monitor of the Nile (*V. Niloticus*, Fitz.), common in the rivers of Egypt and of western and southern Africa, and attaining a length of 5 or 6 ft., of which the head is about one twentieth, the neck one ninth, and the tail nearly one half; the teeth are 30 above and 22 below; the general color above is greenish gray with black dots, with four or five yellow V-shaped marks pointing backward upon the nape, bands of yellow eye-like spots on the back, a wide black band on the shoulder, and a narrow one edged with pale green on each temple; whitish below, with brown transverse bands, and the claws black. From its supposed usefulness in devouring the eggs of the crocodile, it was highly esteemed by the ancient Egyptians. Other aquatic species are found in the East Indies, and in Australia and its archipelago. Of the terrestrial monitors the best known is the *V. scincus* (Merr.), the skink of the ancients, the land crocodile of Herodotus, the *varan* of the Arabs, and the genus *psammomosaurus* of Fitzinger. This is very common in the sandy deserts of Egypt; it is about 3 ft. long, of which the rounded tail is more than half. The color of the upper parts varies from brown to yellow, spotted and banded with one or the other; it is less carnivorous and ferocious than the aquatic monitors.—Cuvier, in his *Ossemens fossiles*, has referred to the family of monitors several gigantic fossil reptiles, as the *proto-rosaurus* (H. de Meyer), from the coppery schists of Germany; the *mosasaurus* (Conybr.), over 30 ft. long, intermediate between monitors and iguanas, from the calcareous strata of Maestricht; the *geosaurus* (Cuvr.), 12 or 13 ft. long, from an iron mine near Mannheim; and the *mequolosaurus* (Buckland), about 40 ft. long, from the vicinity of Oxford, placed by Pictet among the dinosaurs, having certain mammalian characters.—The name of monitor is sometimes given to some American lacertian lizards, especially of the genus *sauvator* (Dum. and Bibr.), more properly called safeguards, corresponding in part to *tupinambis* (Daud.) and *tejus* (Merr.), and to *monitor* (Fitz).

**MONK.** See Monachism.

**MONK, George**, duke of Albermarle, an English general, born at Potheridge, Devonshire, Dec. 6, 1608, died in London, Jan. 3, 1670. At the age of 17 he was a volunteer in an unsuccessful expedition against Cadiz under his relative, Sir Richard Grenville. About a year later he enlisted in the force sent to the isle of Ré, and remained in the service till 1628. Soon after the peace of that year he entered the service of the United Provinces, and returned to England about 1638 with the rank of captain. He soon received an appointment in the army of Charles I., under whom he served with the rank of lieutenant colonel in the two expeditions undertaken just before the conference of Ripon (1640). In 1642 he was appointed colonel of the forces sent to suppress the Irish rebellion, and remained in this service till the breaking out of the civil war. In 1643 he was recalled, but was arrested immediately on his landing in England, and deprived of his office, on suspicion of his favoring the parliament (September). This was so satisfactorily disproved that he was speedily restored to command and promoted to be major general of the Irish brigade, then (January, 1644) engaged in the attack on Nantwich. He had scarcely arrived at that place when he was surprised, defeated, and captured by Sir Thomas Fairfax; and he was imprisoned in the tower for about two years. On his release both parties eagerly endeavored to secure his services; and in November, 1646, he was finally induced by arguments and bribes to take the "solemn league and covenant" and espouse the parliamentary side. He was at once sent to Ireland, and commanded there against O'Neill from 1647 to 1649, exhibiting such military talent as to gain the high opinion of Cromwell, who in 1650 made him lieutenant general of ordinance in the expedition against the Scotch. Here he greatly distinguished himself, especially at the battle of Dunbar. He was now appointed commander-in-chief in Scotland, completed the conquest of the country, and having fully subjugated it, and compelled the formal union of Scotland with the commonwealth, he returned to England in 1652, leaving a reputation for great power and energy, but also for occasional cruelty; the most noteworthy example of the latter quality being his butchery in cold blood of the governor and 800 of the garrison of Dun-dee (1651). In the war against the Dutch, Monk was sent into the channel with a fleet which he commanded jointly with Gen. Dean till the death of the latter on June 2, 1652, in an action in which the final success of the English was due to Monk's persistency in maintaining the fight till the arrival of reinforcements under Blake. He was commander of the fleet in the action on July 31 (new style, Aug. 10), 1658, in which Van Tromp was killed and the Dutch defeated. In 1654 he suppressed the royalist insurrection in Scotland, and afterward kept that kingdom under the full control of the commonwealth until the death of Cromwell. From that time he devoted himself to the acquisition of personal power, striving to conciliate both the royalists and their opponents. When Richard Cromwell resigned the protectorate, in 1659, Monk declared for the parliament, and marched to London with 7,000 men; yet he acted with such skillful duplicity that while he now had the whole country practically under the control of himself and his troops, it was impossible to foresee in what way he would use the power he had acquired.
This course he continued after his arrival in London, and his first decisive act, compelling the parliament to readmit the expelled members, was only performed after a long study of the tendency of public opinion. From this time, however, his actions were rapid and decisive. He brought the army, with which he was always exceedingly popular, into a very perfect state of organization; and the restored members of parliament having brought about his appointment as commander-in-chief, he began to fill the principal offices in the army with royalists. This accomplished, he dissolved the old parliament and assembled a new one, to which, on May 1, 1660, he introduced Sir John Greenville, ambassador from the banished Charles II., with proposals for a restoration of the king. Everything having been prepared for this step by Monk, the proposals were at once accepted, and Charles landed at Dover. Every favor was now conferred upon Monk, and besides the titles of duke of Albemarle and earl of Torrington, with several minor dignities, he received large grants of money and lucrative offices. He resided in London, and continued active in public affairs. In 1664 he presided at the admiralty. In 1665 he displayed great bravery and ability as governor of London during the plague. In 1666 he again commanded (with Prince Rupert) a naval force against the Dutch, and served with much distinction; but he returned from the expedition ill of dropsey, of which he died. He was buried in Westminster Abbey. —See "Life of Monk," by Skinner (London, 1751), and by Guizot (Paris, 1851; English translation by Wharncliffe).

MONK, James Henry, an English author, born in Huntingford, Herts, early in 1784, died at Stapleton, near Bristol, June 6, 1856. He studied at the Charterhouse, and at Trinity college, Cambridge, where in 1807 he became assistant tutor, and in 1808 professor of Greek, but resigned that office on becoming dean of Peterborough in 1822. In 1830 he became bishop of Gloucester. His principal work is the "Life of Bentley" (2 vols. 4to, 1831; revised ed., 1883).

MONKEY, the common name of the family simiidae of the order quadrumanus. The teeth are 32 to 36, and more or less approximate; the canines are larger than the incisors, the upper ones separated by a considerable interval from the lower; the face denuded; the fore feet often larger than the hind, and the middle finger of both hands and feet the longest; opposable thumbs on fore and hind limbs, chiefly formed for grasping; mamma pectoral, two or four; stomach simple. Their food consists of vegetables and insects. Their habits are generally arboreal, and their habitat the forests of tropical America, Asia, and Africa. The monkeys of the new world are entirely distinct from those of the old; the former have always been called simia platyrhini, or broad-nosed monkeys, and the latter simia catarrhini, or narrow-nosed monkeys.—The platyrhini have the nostrils wide apart, on the sides of the nose as it were; they have no cheek pouches nor callosities on the rump, and their long tails are generally prehensile; the hands have either four or five fingers, the first or thumbs very slightly if at all opposable; the teeth are: incisors 2/2, canines 2/2, molars 4/4 =36; they inhabit the warm parts of South America. The marmosets have been described under that title, and the remainder of the tribe may be divided into howlers and sapajous. The howling monkeys belong to the genus mycetes (Illiger), and are characterized by a pyramidal head, beard, face, pentadactyous hands and feet, and tail naked at the end on the lower surface; the lower jaw is very high, and the hyoid bone is expanded into a kind of drum, which renders the voice so resonant and loud that their troops make a most frightful noise during the night; they are the largest and fiercest of the American monkeys, resembling the baboons in disposition and facial angle, and the gibbons (hylobates) in their noisy and gregarious habits. The species are most abundant in Guiana and Brazil, where 30 or 40 are often seen on a single tree. The brown howler or araguato (M. urinus, Humb.) is reddish brown, with long hair and beard, and bluish black face; it is nearly 3 ft. long, exclusive of the tail. There are several other species. The sapajous are more slender, with flatter faces, longer tails, and milder dispositions than the howlers, resembling the gennons or long-tailed monkeys of the old world. In the genus aletes (Geoffroy), the head is rounded, the limbs very long and slender, the fore hands without thumbs, or with very rudimentary ones, and the tail long and prehensile and bare at the tip beneath. The conita (A. paniscus, Geoffr.) is entirely black; it is a timid, mild animal, rather sluggish when not excited, but exceedingly agile among the trees; as it swings from the branches by the tail it looks not un-

![Araguato (Mycetes urinus).](image)
There are several other species, all lively and mild, inhabiting Guiana. In the genera hitherto mentioned, the nails are flattened and rounded; in the next three they more resemble claws, and the animals included in them have more carnivorous propensities, eating meat, insects, and small birds which they seize. In callithrix or tee-trees (Geoffr.), of which the type is the staminiri or squirrel monkey (C. seivureus, Geoffr.), the ears are proportionately large, the body slender, the tail longer than the body, entirely hairy, and not prehensile; the color is grayish brown, lighter beneath, with reddish limbs and black muzzle; the body is 7 or 8 in. long, and the tail 10 or 12. Other species are described, all active and beautiful, with carnivorous propensities; they inhabit principally Brazil and Guiana. In aotes (Humb.; nycti- pitheca, Spix) the two middle upper incisors are broad, and the canines moderate; the eyes large; hind feet longest; tail longer than the body, not prehensile; nocturnal in its habits, living in pairs, resembling the lemurs of South Africa. (See Douroucouli.) The last genus of the American monkeys which need be mentioned is pithecia (Desm.), characterized by a round head, short muzzle, long canines, tail generally shorter than the body, entirely hairy, and not prehensile; they are nocturnal and gregarious, greatly resembling human pigmies, and said to be active, strong, and almost untamable. The couxio or black saki (P. satanas, Humb.) is dusky black, with a purplish tinge beneath, and with the tail is about 2 ft. long. The monk saki (P. chiropotes, Humb.) is brownish red, and of all the American species bears the closest resemblance in its features to man; the expression of the face is fierce and melancholy, the chin is covered with a thick beard, and the eyes are large and sunken; it is said to drink from the hollow of the hand, and to be very careful not to wet its beard. The cacaio or black-headed saki (P. melanocephala, Desm.)

LIKE A LARGE BLACK SPIDER, AND IT IS COMMONLY CALLED SPIDER MONKEY; THE TAIL IS NOT ONLY A FIFTH HAND FOR PURPOSES OF PROGRESSION, BUT AN EXQUISITE ORGAN OF TOUCH. THERE ARE SEVERAL SPECIES, WHICH LIVE IN TROOPES ON THE BANKS OF THE AMAZON AND ORINOCO. Lagothrix (Geoffr.) differs from the last chiefly in the hands having a thumb and in the greater fineness of the hair; the L. Humboldtii (Geoffr.) is grayish black, about 2 ft. long, with the prehensile tail longer than the body. In the genus cebus (Geoffr.) the head is rounded, and the long tail is hairy throughout and prehensile; the monkeys of this genus are very active, excellent climbers, with well formed hands; they are small, mild and playful, and gregarious. The horned sapajon (C. fatuellus, Geoffr.) is blackish brown, with the face surrounded with whitish and the hair of the forehead rising in two lengthened tufts above the eyes. The capuchin monkey (C. capucinus, Exel.) varies from grayish white to olive, with a black crown like a monk’s cap.
is about a foot long; the color of the body is yellowish brown, with the head black; there is no beard, and the tail is so short that Spix has placed it in a new genus *brachyurus*; it is weak, inactive, and very timid. The yarke (*P. leucocephala*, Audebert) is black with the head white; the hair is very long. These and several other species inhabit the woods of Guiana in troops, where they are generally called night or fox-tailed apes. — Of the old-world monkeys, or *catarrhini*, the largest have been mentioned in the articles *Ape*, *Baboon*, *Chimpanzee*, *Gibbon*, *Gorilla*, and *Macaque*; so that it only remains to notice the smaller and long-tailed species. This division of the monkeys has the same number of teeth as man, viz., 32, and similarly arranged, except that the incisors are more prominent, and the canines larger and separated from the incisors; there is a thin septum between the nostrils, hard naked skin or callosities on the rump, pouches on the sides of the face between the cheeks and the jaws; they generally have tails, though these are absent in the larger anthropoid apes; they are found in the warmer parts of Asia and Africa, only one species being naturalized in Europe (the Barbary ape on the rock of Gibraltar). The first of the monkeys not already noticed, connecting the guenons or long-tailed monkeys with the gibbons or long-armed apes, is the *prebytis* or capped monkey; this has no cheek pouches, but has naked callosities, a long tail, and arms reaching to the knees. The *P. mitrula* (Eschs.) has the body 1 ft. long, and the tail about as long; the hair is bluish gray above and grayish white below, with a black line from the ears across the head; it is a native of Sumatra. In the African genus *delobus* (III) there are no thumbs on the hands, and the limbs are long and slender as in the spider monkeys (*ateles*) of the new world. The king monkey (*C. polymus*, Geoffr.) is remarkable for the long, coarse, and flowing hair on the head, like a full-proboscsis 4 in. long, at the end of which are the nostrils; the body is thick and the limbs stout; there are cheek pouches and callosities, and the tail is longer than the body; the color is reddish brown, with lighter patches on the lower back, and the face black; the body is about 2 ft. long; they are very active and noisy, and inhabit in large troops the forests of Borneo. The Cochin-China monkey (*lastopyga nemara*, III.) is a very singularly marked species; the muzzle is slightly elongated, the face bare, the hands longer than the forearms, with short and slender thumbs; it has cheek pouches, but no callosities, and the tail is long. The colors are brilliant, the upper part of the head being brown with a chestnut frontal band, long hair of cheeks dirty white, forearms and tail white, the hands and thighs black, legs chestnut, and body olive gray; it stands nearly 4 ft. high. The first genus of the guenons is *semnopithecus* (F. Cuv.), with round head, flat nose, long limbs, short thumbs, small cheek pouches and callosities, slender form, very long and thin tail, and canines much longer than the incisors; they inhabit India and its archipelago. The *S. entellus* (F. Cuv.) has a body about 1 1/2 ft. long and a tail 3 ft.; the hind limbs are much longer than the anterior; the color is yellowish white, paler beneath, with the face, forearms and hands, legs and feet, black; it appears slow, sad, and stupid when at rest, but when roused is extremely active; it is very sensitive to cold, and is therefore rarely seen in menageries. It is called *hominanus* by the Hindoos, who consider it a crime to kill one, and believe that the person who destroys one will surely die within a year; it occupies a conspicuous place among their divinities. There are several other species in Sumatra. The genus *cecropithecus* (Erx.) differs from the last in the larger facial angle, more elegant shape and coloring, longer posterior limbs, and milder and more affectionate disposition; it has only four tuberces to the last lower molar, instead of five, as in *semnopithecus*. The varied monkey (*C. mona*, Geoffr.) is the handsomest of all; the body is

![Proboscis Monkey (Nasalis larvatus).](image)

![Entellus (Semnopithecus entellus).](image)
MONKEY

chestnut, upper part of head bright yellowish green, cheeks yellow, outside of limbs and tail blackish, with a spot of white on the nates; it is a native of Africa, cunning, active, intelligent, and playful. The Diana monkey (C. Diana, Geoffr.) is so called from the white crescent on the forehead; the chin and throat are white; it is about 1½ ft. long with a tail of 2 ft. There are many other species, most, like the first two, from Africa. The mangabeys (Cercopithecus, Geoffr.) begin to come near the baboons in the more lengthened muzzle and receding forehead, though they have the long tail of the guenons; they are found in Africa and India. The green monkey (C. sabana, Geoffr.) is a native of Africa and the Cape Verde islands, and is very often seen in captivity on account of its lively and playful manners; the color is olive green above, shading into white below, and the face is black. The malbrouck of Bengal (C. cynomorus, Geoffr.) is olive brown above, shading into white, with a white band over the eyes; it is an excellent climber and very active, and is often seen in menageries. The white-eyed mangabey (C. fuliginosus, Geoffr.) is sooty black with white and very conspicuous upper eyelids; it is a native of Africa. These and numerous other species of Asia and Africa are generally easily domesticated when young; they are good-natured, playful, and free from the disgusting habits of the larger baboons.—The restriction of the catar- rhini to the old and of the platyrhini to the new world prevailed in the tertiary geological epochs. Fragments of a jaw and some teeth found in the eocene sand of Suffolk, England, were referred by Owen to the genus Macacus under the name of M. eocenus; this furnishes a proof of the former more elevated temperature of Europe, monkeys having lived during the eocene period 15° further N. than now. In the miocene of France, in lat. 43° N., were found portions of a jaw and teeth, very anthropoid in appearance, belonging to what De Blainville has called pithecus antiquus, which some have thought nearer to man than is the chimpanzee. Other fragments have been found in England, Greece, and France, which have been referred to the genera maccacus, pithecus, and semnopithecus. In the Sivalik hills of India have been discovered specimens of semnopithecus nearly as large as the oranges, and some resembling baboons. In South America, Lund found in Brazil, in lat. 18° S., specimens which he referred to the genera cebus, calithrix primamvus (twice the size of any living species), and protopithecus brasiliensis, which must have attained a height of 4 ft.; he also found there ouistitis (jaculus grandis) twice as large as any now living.

MONKSHOOD. See ACONITE.

MONMOUTH, a central county of New Jersey, bordering on the Atlantic ocean, drained by the Nevisink, Shrewsbury, Shark, and Toms rivers; area, about 800 sq. m.; pop. in 1870, 46,195. Its surface is generally level, with elevations toward the northeast. It is traversed by the Freehold and Jamesburg, the New Jersey Southern and Port Monmouth branch, the Toms River and Waretown, and the Tuckerton railroads. The chief productions in 1870 were 176,473 bushels of wheat, 46,567 of rye, 760,479 of Indian corn, 180,461 of oats, 1,263,403 of Irish and 50,892 of sweet potatoes, 41,582 lbs. of wool, 415,367 of butter, and 32,389 tons of hay. There were 6,035 horses, 1,254 mules and asses, 8,038 milch cows, 4,244 other cattle, 14,099 sheep, and 10,890 swine; 13 manufactories of brick, 23 of carriages and wagons, 10 of men's clothing, 5 of furniture, 3 of gold leaf and foil, 5 of tanned and 3 of curried leather, 7 of canned vegetables, 4 distilleries, 28 flour mills, and 8 saw mills. Capital, Freehold.

MONMOUTH, a city and the capital of Warren co., Illinois, situated at the intersection of the Chicago, Burlington, and Quincy, and the Rockford, Rock Island, and St. Louis railroads, 90 m. N. W. of Springfield; pop. in 1870, 4,662. It is the seat of Monmouth college, established in 1856, and of the theological seminary of the Northwest, established in 1859, both under the control of the United Presbyterians. The former institution admits both sexes, and in 1873-4 had 9 instructors, 138 preparatory and 87 collegiate students, and a library of 1,860 volumes. The seminary in the same year had 3 professors, 12 students, and a library of 2,442 volumes. The city has five hotels, three public halls, two grain elevators, two flouring mills, a planing mill, three manufactories of ploughs, one of files, one of school and church furniture, three national banks, an academy, graded public schools, a library, three weekly newspapers, two monthly periodicals, and nine churches.

MONMOUTH, a market town and borough of England, capital of Monmouthshire, in a valley at the confluence of the Wye and Monnow, 110 m. W. N. W. of London; pop. in 1871, 5,874. Its castle, once the residence of John of Gaunt, is now a mere ruin. There are large iron
works, and the Wye fisheries in the vicinity are flourishing. The trade consists chiefly in the export of bark and timber. The battle of Monmouth, in which Owen Glendower was defeated, was fought May 11, 1405.

**MONMOUTH, Battle of**, an engagement between the American forces under Washington and the British under Sir Henry Clinton, at Freehold, Monmouth co., N. J., June 28, 1778. On June 18 Clinton evacuated Philadelphia and marched toward Brunswick, with a view of embarking on the Raritan. Washington broke camp at Valley Forge, sent forward some light troops to harass the enemy, and started in pursuit. At Allentown Clinton suddenly turned to the right by a road leading through Freehold to Sandy Hook, and Washington determined at once to give him battle. The evening of the 27th found the main body of the enemy encamped on high ground near Monmouth court house in the town of Freehold, while the American advance, about 4,000 strong, under Lee, was posted at Englishtown, 5 m. distant, with the main body about 3 m. in the rear. Early on the 28th Lee engaged the rear division of the enemy, his orders being to hold it in check until the main body under Washington could come up. The Americans were successful at first, but the whole body soon fell into a confusion in which their commander seemed to participate, and commenced a disorderly retreat, closely followed by the British. Washington, advancing with the main body, received the first intimation of this movement in the crowds of fugitives. He rode up to Lee and reprimanded him vehemently; then, rallying the fugitives, he re-formed them, and hastened back to bring up the main body. Lee, resuming his command, held his position with spirit until compelled to retire, and brought off his troops in good order. The main body, which had taken a favorable position on an eminence, with a morass in front and a wood in the rear, opened an effective cannonade from both wings upon the British. The latter, after an ineffectual attempt to turn the American left under Lord Stirling, directed their chief efforts against the right commanded by Greene, where Wayne, under cover of an orchard, was harassing their centre by a severe fire. To dislodge him, Col. Monkton advanced with a column of royal grenadiers, but fell at the head of his troops, who were repulsed with considerable loss. The enemy at length fell back to the ground occupied by Lee in the morning, and during the night Clinton effected a noiseless retreat. Excessive heat and fatigue rendered pursuit impracticable. The American loss was 69 killed and 160 wounded; that of the British probably nearly 300 killed and 100 prisoners, including wounded. On both sides many men died from the heat alone. For his conduct in this battle Lee was court-martialled and suspended for one year from his command.

**MONMOUTH, Geoffrey of.** See Geoffrey.
a popular than on a legal basis; but when the duke of York returned to court, the story of the marriage of Charles II. and Lucy Walters was gravely urged, and the king deemed it necessary to deny it in the most public and formal manner. The part Monmouth had in the conspiracies of 1688 led to his flight to Holland, after considerable negotiation with the king for pardon. When Charles II. died, Feb. 6, 1685, he left the Hague, and dwelt by the suggestions of British exiles, headed a small expedition, which arrived at Lyme Regis, June 11. At first the duke met with some success; but his forces were beaten at Sedgemoor, July 6, and on the 8th he was captured and taken to London, where he had an interview with James II., of whom he vainly begged his life in absent terms. He was executed under an act of attainder two days after his arrival in the capital. His followers continued for the years to come that he was alive, and it was supposed by some that he was the man with the iron mask who was so long a prisoner in the Bastile. His wife, a woman of superior talents, from whom he had been separated, survived him nearly 47 years, and married Charles, third Lord Cornwallis. She is the duchess of Scott's "Lay of the Last Minstrel," and Monmouth is the Absalom of Dryden's "Absalom and Achitophel."

MONMOUTHSHIRE, a maritime county of England, bounded S. by the Bristol channel and the estuary of the Severn; area, 575 sq. m.; pop. in 1871, 195,831. The coast, 22 m. in extent, is exposed to the high spring tides that rush up the Severn from the Bristol channel and sometimes attain an altitude of 60 ft. Vast sea walls and earthworks have been erected. The surface toward the north is mountainous and rocky; adjoining the Severn and the sea is a spacious plain, which the river Usk divides into two parts, called the Wentloog and Caldecet levels. The principal mountains are: Pen-y-Fan, on the W.; Monmouth, 1,356 ft. high; Blawen-ge mountain, 1,720 ft.; and Skyrewyd Vawr, or Holy mountain, 1,498 ft. The chief rivers are the Wye, Usk, and Monnow, the two former of which are famous for their salmon. The soil of the vales and plains is generally fertile. Iron, coal, lead, and building stone are produced. The iron and coal of this county are shipped at Newport. The area of its mineral districts is estimated at 89,000 acres. Chief towns, Monmouth, the capital, Newport, Abergavenny, and Chepstow. Monmouthshire was originally a part of South Wales, and the Welsh language is still largely in use there.

MONNARD, Charles, a Swiss author, born in Bern in 1790, died in Bonn, Germany, Jan. 12, 1865. He was educated in Lausanne and Paris, and in 1817 became professor of French literature in Lausanne. He studied ecclesiastical and civil law, and in May, 1824, a law having been passed to prevent the propagation of Methodism in the canton of Vaud, he declared it unconstitutional, and encouraged his friend Vinet to stand up for liberty of conscience, publishing for him the treatises De la liberté des cultes (1826) and Observations sur les sectaires (1829). The former treatise created considerable disturbance. A German translation appeared in 1843. The second treatise caused the suspension of Monnard from his professorship, and his removal to Geneva, whence however he soon returned, became a representative, and was noted for his defence of Swiss independence when in 1838 Louis Philippe demanded the expulsion of Prince Louis Napoleon. After the revolution of 1846 he retired from politics, and accepted the professorship of French literature which was founded for him by the king of Prussia at the university of Bonn.

MONNIER, Henri Bonaventure, a French author, born in Paris, June 6, 1790. He was a clerk in the ministry of justice when he began to study painting under Girodet. He acquired celebrity as a writer of illustrated works, with exquisite caricatures, and especially by his Scènes populaires (1830), Nouvelles scènes populaires (5 vols., 1835-36), and Mémoires de Joseph Prudhomme (new ed., 3 vols., 1857). He wrote and personated the principal part in Grandeur et décadence de M. Joseph Prudhomme (1852); and in his equally entertaining vaudeville Roman chez la portière (1855) he personated the portière.

MONNIN, Marc, a French author, born in Florence about 1829. He spent the early part of his life in Italy, and many of his writings relate to that country. He has published the staff of the Journal des Débats. Among his numerous works are: Étude historique de la conquête de la Sicile par les Sarraïns (Geneva, 1847); Garibaldi, histoire de la conquête des Deux-Siciles (Paris, 1861); Fonti et les Tompéiennes (1864); Les aléas de l'Égypte (1858), which contained interesting disquisitions on dramatic art; and Polisie (1871).

MONO, an E. county of California, bordering on Nevada, and bounded W. by the Sierra Nevada mountains; area, 4,176 sq. m.; pop. in 1870, 430, of whom 42 were Chinese. It is watered in the south by Owen's river, and in the north by the forks of Walker's river. Mono lake, a considerable body of water near the centre, receives several streams, but has no outlet. The slope of the Sierra Nevada is heavily timbered; the rest of the county consists of hills and mountain spurs, with small valleys of tillable land and larger tracts suitable for grazing. Gold and silver are found, two mines of the former and three of the latter being in operation in 1870. The chief productions were 6,144 bushels of wheat, 4,173 of oats, 12,704 of barley, 4,928 of potatoes, 7,000 lbs. of wool, 35,685 of butter, and 2,114 tons of hay. There were 728 horses, 3,997 cattle, and 550 swine; 1 flour mill, 8 saw mills, and 8 quartz mills. Capital, Bridgeport.
MONOD. I. Jean, a French clergyman, born in Geneva in 1765, died in Paris, April 28, 1836. He officiated as pastor of the Reformed church in Paris until the outbreak of the first revolution, when he removed to Copenhagen, where he entertained the duke of Orleans, the future king Louis Philippe. In 1808 he returned to Paris, and in 1830 became president of the consistory. II. Frédéric Joël Jean Gérard, eldest son of the preceding, born near Morges, Switzerland, May 17, 1794, died in Paris in 1868. He received his theological education at Geneva, and after the death of his father became pastor of the Oratoire in Paris. His ability as a preacher and his high character made him a leader among the evangelical Protestants of France. After officiating in the Oratoire for more than 12 years, he seceded from the national Protestant church, April 22, 1849, because it did not insist upon "the acknowledgment of Christ as a divine Saviour" as a condition of membership. He organized the Free church of France, and was one of the organizers of the Free church movement in Scotland. In 1858 he visited the United States, to enlist the sympathies of Americans in the movement. For several years he edited the Archives du Christianisme, and he published several sermons and lectures.—His son JEAN, born in Paris in 1822, was pastor at Marseilles and at Nimes, and was chosen professor of theology at Montauban in 1865. III. Adolphe Frédéric Théodore, brother of the preceding, born in Copenhagen, Jan. 21, 1802, died in Paris, April 6, 1856. He was educated at Geneva, and he had to the same views in regard to the divinity of the Saviour as his brother Frédéric, yet remained in the national church. He became one of the pastors of the Reformed church in Lyons, whence he was dismissed in consequence of his rigid adherence to evangelical principles. He was afterward professor in the theological school at Montauban, and in 1849, on the succession of his brother, he was invited to fill his place at the Oratoire. He held this post until his death, and gained a high reputation for pulpit eloquence. He is the author of Lucile, ou la lecture de la Bible (1841); Saint Paul (1850); la Femme (1862); and several volumes of discourses. Most of his works have been translated into English.

MONOGRAM (Gr. μονογραμμα, letter), a character or cipher formed by the combination of two or more letters of the alphabet. Monograms were common in antiquity, and their use was almost universal at the beginning of the Christian era. Many are found on Greek and Roman coins, medals, and seals, the names of cities and states being represented monogrammatically where it was an object to save space, and on the leaden bullæ of Greece and Sicily. The Chrismon or monogram of Christ, with which are combined rings, lamps, vases, tombs, paintings, and ecclesiastical documents were ornamented in the middle ages, is a combination of the Greek letters X and P, and represents the first two letters of ΧΡΙΣΤΟΣ. The X is sometimes made to form a cross, and sometimes entirely detached from the P and used in connection with other letters, particularly A and Ω. The illustrations are all from tombs in the Roman catacombs, the first two of the 2d century. The Chrismon was the symbol borne on the labarum of Constantine, and it was impressed on the coins of nearly all the succeeding emperors of the East. It is now nearly superseded in ecclesiastical ornamentation by the monogram of Charlemagne, consisting of the Greek letters ΗΝ, the abbreviation of ΗΝΟΥΣ. In the time of Charlemagne monograms were in general use on coins and seals, and in manuscripts. His own monogram occurs as a subscription to a document in the British museum of the date 801; as will be seen by the illustration, it takes in all the letters of his name (Carolus). The popes and many other sovereigns of the middle ages used monograms for signatures, as did also the early painters, engravers, and printers. Many modern monograms are but imitations of mediaval ones, but the taste for their use on seals, plate, paper, &c., has led to the production of designs which excel the best middle-age examples both in beauty and in intricacy.—See Brilliot, Dictionnaire des monogrammes (24 ed., 3 vols. 4to, Munich, 1832-48); Binterim, Die vorzüglichsten Denkwürdigkeiten der christlich-katholischen kirche (7 vols., Mentz, 1825-93); and Nagler, Die Monogrammisten, &c. (4 vols. 8vo, Munich, 1857-63).

MONOMANIA. See Insanity.

MONONA, a W. county of Iowa, separated from Nebraska by the Missouri river, and intersected by the Little Sioux; area, about 900 sq. m.; pop. in 1870, 3,654. It is covered with prairie and has a fertile soil. The Sioux City and Pacific railroad passes through it. The chief productions in 1870 were 88,990 bushels of wheat, 285,457 of Indian corn, 50,346 of oats, 24,026 of potatoes, 18,783 lbs. of wool, 85,611 of butter, and 16,123 tons of hay. There were 1,413 horses, 6,374 cattle, 4,049 sheep, and 2,732 swine. Capital, Onawa.

MONONGAHELA RIVER, one of the head branches of the Ohio, formed by the union of the West fork and Tygart's Valley river in Marion co., W. Va., flows N. into Pennsylvania, where it receives the Cheat river, its principal tributary, and the Youghiogheny, and unites
with the Alleghany to form the Ohio at Pittsburgh; length, exclusive of branches, about 150 m., or including the Tygart's Valley river or East fork (which rises in Randolph co., W. Va.), 300 m. At its mouth the width is nearly 400 yards. It is navigable for large boats to Brownsville, Pa., 60 m. from its mouth, and for small boats to Fairmont, W. Va., at its head.

MONONGALIA, a N. county of West Virginia, bordering on Pennsylvania, and intersected by Monongahela and Cheat rivers; area, about 500 sq. m.; pop. in 1870, 18,547, of whom 231 were colored. The surface is uneven, being mountainous toward the east, where it is crossed by Laurel hill, an extreme western ridge of the Alleghenies; the soil is fertile. The Baltimore and Ohio railroad passes through the S. W. part. The chief productions in 1870 were 111,805 bushels of wheat, 301,328 of Indian corn, 148,072 of oats, 23,772 of potatoes, 55,856 lbs. of wool, 345,573 of butter, and 12,030 tons of hay. There were 4,238 horses, 8,110 cattle, 17,371 sheep, and 7,324 swine; 7 Hour, 3 lumber, and 2 woolen mills, and 8 tanneries. Capital, Morgantown.

MONOPHYSITES (Gr. μονοϕυσίται, from μόνος, single, and ϕύσις, nature), the followers of Eutyches, who maintained that in Christ there is "only one nature, that of the incarnate word," his human nature having been absorbed by the divine. Eutyches had been led to this doctrine by the mixture or confounding of the divine and human natures in Christ, against Nestorius, who taught that "the divine nature was not incarnate in Jesus, but only attendant on him, being superadded to his already formed human nature." Eutyches was warmly supported by the monasteries of Constantinople, and by those of Egypt, headed by Dioscurus, bishop of Alexandria. His opinion, condemned in 448 at Constantinople, was reaffirmed by the "robber synod" of Ephesus in 449, through the influence of Dioscurus and his partisans, aided by the abbot Barsuma and his Syrian monks, but especially through the active support of the emperor Theodosius II. This decision was reversed in 451 by the general council of Chalcedon, which decreed that after the incarnation, the one and same Christ subsists in both natures without mixture, change, division, or separation. This decision, which the Eutychians termed sheer Nestorianism, only made them more tenacious of their doctrine. Hence they were called Monophysites by their opponents, who in turn were denominated indiscriminately Diophysites or Nestorians. The great patriarchal sees of Alexandria, Jerusalem, and Antioch, chiefly by means of the numerous monasteries of monks tainted with Eutychianism, fell into the possession of the Monophysites, and these cities, with their dependent churches, were for a long time scenes of the most scandalous and sanguinary violence. The perpetual interference of the Greek emperors in theological disputes, as it had not a little helped the growth of the Nestorian and Eutychian heresies, contributed also to perpetuate the division between the orthodox and the Monophysites. The usurper Basiliscus in 476 was the first emperor to issue doctrinal edicts obligatory on all upholding Monophysitism. In 477 the emperor Zeno gave his support to the Catholics, and in 482 he published a doctrinal condemnation called Heneticon, which was condemned at Rome and rejected by both parties. Every attempt at reunion theretoward made by the imperial authority only served to widen the breach. The emperors Justin and Justinian employed alternately, without success, measures of conciliation and severity. While Justinian tried to win the Catholics by proscribing the writings of Origen favorable to the Monophysites, he irritated them by condemning what is known as the "three chapters," namely, passages from three Antiochian church teachers, in accord with Nestorianism, but justly condemned at Chalcedon. At the same time Justinian's wife Theodora was a most ardent propagandist of Monophysitism. The general council of Constantinople, convened in 553 by that emperor, created irremediable division, on the one hand by the condemnation of the Monophysite tenets, and on the other by the violence done to Pope Vigilius, and the condemnation of the "three chapters." The Monophysites, in the mean while, had fallen out among themselves; some (the Severans) maintaining the corruptibility, others (the Julianists) the incorruptibility of the body of Christ. By adopting the latter doctrine Justinian made (in 564) a last attempt to draw over the Monophysites, but with no other result than to cause a new split among the Catholic bishops. Under his successor the efforts to make the Monophysites accept the decrees of Chalcedon were given up, and they organized as an independent body. The zeal of Jacobus Baraduceus, who in 541 was ordained bishop of Edessa, gave to Syrian Nestorianism a permanent organization, with a patriarch, claiming to be the legitimate successor of the Antiochian patriarchs, at their head. They also received from him the name Jacobites, by which they were thenceforth commonly called. (See Jacobites.) As early as 627, the bishops of Armenia rejected at a national synod, under the presidency of their patriarch Nerses, the decrees of Chalcedon, and organized on a Monophysite basis an independent church. (See Armenian Church.) In Egypt nearly all the churches adopted Monophysitism; the few adherents of the imperial decrees were called Mélchites (i. e., royalists), while the Monophysites received the name of Coptics (i. e., Egyptian) Christians. (See Copts.) With this latter branch of Monophysitism the Abyssinian church is in organic connection. Some smaller branches of these four Monophysite churches spread in other parts of western and in central Asia, but without attaining to any importance.—The history of the Monophysites is most amply treated of by Walch, in his Katerhistorie, vols. vi,
vi., and viii. An extensive extract from this work is given in Schröckl's Kirchengeschichte, vol. xviii. Writings and fragments of the party leaders are contained in Mal's Scriptorum Veterum Nova Collectio, vol. vii., and Spicilegium Romanum, vol. vii. (See MONOTHELITES.)

MONOPOLI, a seaport town of Italy, in the province and 23 m. S. E. of the city of Barl, on the Adriatic; pop. about 12,000. It is the see of a bishop, and has a cathedral with a fine painting of St. Sebastian by Palma, and a chapel enriched with inlaid marbles of all colors. The town has two harbors, which accommodate large vessels, but one of them is exposed to the N. E. wind, which often blows with great violence in the Adriatic. There are extensive manufactories of cotton and linen cloths. About 3 m. from the town are ruins of the ancient seaport Egnatia, which was early the see of a bishop and was destroyed in the 9th century.

MONOTHELITES (Gr. μονοθελία, from μόνον, single, and θέλειν, to will), the name of a sect which maintained that in Christ there was but one will and one voluntary operation, while they admitted the doctrine of two natures after the incarnation. The origin of Monothelitism was due to the effort made by the emperor Heraclius to conciliate the numerous Monophysite churches. (See ΜΟΝΟΦΥΣΙΣΤΕΣ.) At the suggestion of Sergius, patriarch of Constantinople, a profession of faith was drawn up affirming that in Christ there is "only one mode of willing and working," and this was embodied in 639 in an imperial edict called Ekthesis. Cyrus, patriarch of Alexandria, at the instance of Sergius, made this formula a part of a doctrinal compromise, which was adopted by an assembly of Monophysite bishops held in that city, and thus led to the reunion of a large number of Monophysite churches. Sophronius, then a priest of Alexandria, strenuously but vainly opposed the adoption of this formula; and being soon afterward chosen patriarch of Jerusalem, he denounced the compromise in his inaugural letter to the bishops of Christendom. Sergius thereupon wrote to Pope Honorius I. requesting him to use his authority with Sophronius, and forbid the use of formulas expressing the existence in Christ of two wills and two voluntary operations. To this request Honorius assented. (See ΑΥΓΟΝΟΣ.) But after his death (638), the bishops of Rome placed themselves at the head of the opposition, and a new decree of the emperor Constant II., called Typos (648), designed to enforce peace by a prohibition of the controversy, had not the desired effect. The first council of Lateran (649) under Pope Martin I. condemned the Monothelites and the two imperial laws. The pope suffered imprisonment and died in exile for this decree, but some years later (680) the sixth oecumenical council, held at Constantinople, recognized in Christ two wills made one by the moral subordination of the human. The Monothelites obtained once more a transient

victory under Philippius Bardanes (711-12), who had been brought up by the patriarch Macarius; but after the elevation of Anastasius II. to the throne, all the Monothelites were forced to submit, and the sect maintained itself only in a corner of Asia, outside of the Byzantine boundaries, until the 12th century, when they united with the Roman Catholic church. (See MARONITES.)—A history of the Monothelite heresy was written by Combes, in his Auctarium Patrum, vol. ii. (Paris, 1648).

MONOTREMATA (Gr. μονότρημα, single, and τρύχη, opening), an order of implantal mammals; the name is derived from the fact that the intestinal, generative, and urinary organs open into a common cloaca, as in birds and reptiles. The order includes the ornithorhynchus and the porcupine ant-eaters (echidna), from Australia and Tasmania. They are the lowest mammals, and have many characters of birds and reptiles in their structure and mode of reproduction; they have no abdominal pouch, but the marsupial bones are present; at the top of the breast bone is an episternum with lateral arms forming the chief support of the scapular arch, on the top of which the true clavicles, like the furcular bone of birds, are situated; the coracoid bones extend also to the sternum, and are surmounted by eucoracid bones; in the scapular arch, therefore, they resemble in some respects birds, in others lizards and enaliosaurians. The eyes are very small, the external ears absent, and the face projects in the form of a naked beak, without teeth or soft movable lips; the teeth are replaced by small horny plates; some authors, as Wagner, have ranked them among edentates. The feet are five-toed, with long nails; the males have a long spur on the hind legs, the groove of which communicates with a glandular organ, whose secretion has been erroneously supposed to be poisonous; the mammary orifices are mere slits in the skin of the abdomen, without elevated nipples, and the female sexual organs resemble those of birds; the young are born alive, and are suckled as in other mammals; the cecum is small; the lungs are spongy and cellular, and enclosed in a thoracic cavity separated from the abdomen by a diaphragm; in the brain there is no corpus callosum, and the pigeminal bodies are simple. (See ΟΡΝΙΘΟΡΧΥΝΧΟΣ, and ΠΟΡΚΟΠΙΝΗ ΑΝΤ-ΕΑΤΕΡ.)

MONREALE, a town of Sicily, in the province and 4 m. S. W. of the city of Palermo, on a steep hill called Monte Caputo; pop. about 16,000. It is the seat of an archbishop, and has one of the most imposing cathedrals of Sicily, containing the tombs of several Norman kings of the 12th century. There is a brisk trade in corn, oil, and fruit raised in the vicinity. Monreale grew up around a splendid Benedectine abbey and church. (now the cathedral) founded by the Norman king William the Good in 1174, and took its name (Royal Mount) from its royal origin.
MONROE, the name of 17 counties in the United States. I. A N. W. county of New York, bounded N. by Lake Ontario and drained by the Genesee river; area, 682 sq. m.; pop. in 1870, 117,568. The surface is generally level, with a slight inclination toward the lake. The soil is very fertile. The county is intersected by the New York Central and several other railroads, and the Erie and Genesee Valley canals. The chief productions in 1870 were 1,061,520 bushels of wheat, 802,261 of Indian corn, 1,217,955 of oats, 480,968 of barley, 990,998 of potatoes, 134,184 of peas and beans, 70,095 lbs. of tobacco, 337,394 of hops, 386,443 of wool, 1,631,050 of butter, 39,558 of cheese, and 74,453 tons of hay. There were 17,151 horses, 16,168 milch cows, 18,172 other cattle, 70,546 sheep, and 17,871 swine. There were 1,160 manufacturing establishments, employing 10,051,090 capital, with annual products amounting to $25,745,407. The chief industries, besides a large number of nurseries for fruit and ornamental trees and plants, were 17 manufactories of agricultural implements, 19 of boots and shoes, 66 of carriages and wagons, 82 of men's clothing, 1 of edge tools, 20 of furniture, 4 of hats and caps, 2 of iron castings, wrought iron, &c., 17 of machinery, 3 of paper, 4 of perfumery and fancy goods, 39 of tin, copper, and sheet-iron ware, 17 tanneries, 50 flour, 17 saw, and 4 planing mills, 3 distilleries, and 18 breweries. Capital, Rochester.

II. An E. county of Pennsylvania, separated from New Jersey by the Delaware river; area, 600 sq. m.; pop. in 1870, 18,362. The surface in some parts is mountainous, and the soil of the valleys is rich. Limestone and slate are found. It is traversed by the Delaware, Lackawanna, and Western railroad. The chief productions in 1870 were 37,082 bushels of wheat, 72,424 of rye, 175,040 of Indian corn, 118,470 of oats, 79,165 of buckwheat, 103,816 of potatoes, 12,089 lbs. of wool, 298,168 of butter, and 17,973 tons of hay. There were 2,870 horses, 4,506 milch cows, 3,718 other cattle, 3,974 sheep, and 5,441 swine; 12 flour, 14 saw, and 2 woolen mills, and 12 tanneries. Capital, Stroudsburg.

III. A S. county of West Virginia, bordering on Virginia, drained by Greenbrier and New rivers; area, 450 sq. m.; pop. in 1870, 11,124, of whom 1,068 were colored. It has an elevated surface, and is bounded E. and S. by the Alleghenies. It is one of the finest grazing counties in the state. The Chesapeake and Ohio railroad passes through the N. part. The chief productions in 1870 were 52,817 bushels of wheat, 11,520 of rye, 170,721 of Indian corn, 59,062 of oats, 12,164 of potatoes, 123,221 lbs. of tobacco, 26,694 of wool, 163,540 of butter, and 5,888 tons of hay. There were 2,555 horses, 3,006 milch cows, 7,189 other cattle, 11,517 sheep, and 5,747 swine.

IV. Capital, Union. W. A central county of Georgia, bounded W. by the Ocmulgee river and drained by several branches; area, 370 sq. m.; pop. in 1870, 17,213, of whom 10,804 were colored. The surface is diversified, and much of the soil fertile. Gold, iron, granite, and plumbago are found. The county is intersected by the Macon and Western railroad. The chief productions in 1870 were 36,917 bushels of wheat, 241,251 of Indian corn, 21,286 of oats, 35,158 of sweet potatoes, 63,892 of butter, and 10,494 bales of cotton. There were 1,041 horses, 1,789 mules and asses, 2,173 milch cows, 589 working oxen, 3,452 other cattle, 1,754 sheep, and 11,018 swine. Capital, Forsyth.

V. A S. county of Florida, forming the W. half of the extremity of the peninsula, bounded W. by the gulf of Mexico, S. W. by the bay of Ponce de Leon, N. by the Caloosahatchie river, and N. E. by Lake Okeechobee; area, 3,066 sq. m.; pop. in 1870, 5,057, of whom 1,026 were colored. In the S. part of the county lie the "Thousand islands," and the Florida Keys are mostly included in it. The surface is mainly flat and marshy, and is partly occupied by the Everglades. The orange and the cocoa palm are indigenous. The productions are confined almost entirely to a few sweet potatoes, and most of the population centres at Key West. In 1870 the county contained 14,066 cattle. Capital, Key West.

VI. A S. W. county of Alabama, drained and bounded S. W. by the Alabama river; area, 950 sq. m.; pop. in 1870, 14,214, of whom 7,972 were colored. The surface is moderately uneven and partly occupied by pine forests. The chief productions in 1870 were 323,486 bushels of Indian corn, 44,788 of sweet potatoes, 6,172 bales of cotton, 4,568 lbs. of wool, 45,037 of butter, and 10,629 gallons of cane molasses. There were 1,068 horses, 975 mules and asses, 3,134 milch cows, 1,134 working oxen, 6,406 other cattle, 3,257 sheep, and 10,746 swine. Capital, Claiborne.

VII. A N. E. county of Mississippi, bordering
on Alabama and intersected by the Tombigbee river; area, about 700 sq. m.; pop. in 1870, 22,631, of whom 14,000 were colored. The surface is a plain, with few trees and covered with rank grass. The soil is a rich calcareous loam. The Mobile and Ohio railroad and its Aberdeen branch pass through it. The chief productions in 1870 were 12,249 bushels of wheat, 415,153 of Indian corn, 55,631 of sweet potatoes, 47,380 lbs. of butter, and 8,562 bales of cotton. There were 1,394 horses, 2,084 mules and asses, 8,455 milk cows, 4,950 other cattle, 2,472 sheep, and 19,599 swine. Capital, Aberdeen. VIII. An E. county of Arkansas, bounded S. W. by White river; area, 1,040 sq. m.; pop. in 1870, 8,386, of whom 3,200 were colored. The surface is generally level, and much of it occupied by cypress swamps. It is intersected by the Memphis and Little Rock railroad. The chief productions in 1870 were 184,358 bushels of Indian corn, and 7,384 bales of cotton. There were 1,256 horses, 896 mules and asses, 1,925 milk cows, 379 working oxen, 2,692 other cattle, 624 sheep, and 10,310 swine. Capital, Little Rock. X. A. S. E. county of Tennessee, bordering on North Carolina; area, 500 sq. m.; pop. in 1870, 12,589, of whom 1,255 were colored. It is drained by Tellico river, an affluent of the Little Tennessee. The Unaka or Smoky mountain lies on the S. E. border. The soil is moderately fertile. The East Tennessee, Virginia, and Georgia railroad passes through it. The chief productions in 1870 were 118,753 bushels of wheat, 415,010 of Indian corn, 56,907 of oats, 15,324 lbs. of wool, and 2,177 tons of hay. There were 2,394 horses, 2,539 milk cows, 6,415 other cattle, 8,346 sheep, and 13,422 swine. Capital, Madisonville. X. A. S. county of Kentucky, bordering on Tennessee and drained by the head streams of Big Barren river and by the Cumberland river; area, 600 sq. m.; pop. in 1870, 9,251, of whom 789 were colored. The surface is diversified and the soil fertile. The chief productions in 1870 were 37,367 bushels of wheat, 747,660 of Indian corn, 112,275 of oats, 13,649 of Irish and 11,899 of sweet potatoes, 674,096 lbs. of tobacco, 33,323 of wool, and 121,954 of butter. There were 4,686 horses, 2,148 milk cows, 5,178 other cattle, 11,505 sheep, and 16,137 swine. Capital, Tompkinsville. XI. A. S. E. county of Ohio, separated from West Virginia by the Ohio river; area, 420 sq. m.; pop. in 1870, 25,779. The surface is hilly and well timbered. It contains beds of coal, and some iron. The chief productions in 1870 were 161,042 bushels of wheat, 629,816 of Indian corn, 306,425 of oats, 98,678 of potatoes, 2,845,255 lbs. of tobacco, 128,006 of wool, 524,887 of butter, and 18,001 tons of hay. There were 7,060 horses, 8,358 milk cows, 10,046 other cattle, 42,198 sheep, and 18,661 swine. There were 29 manufactures of cheese, 7 of furniture, 1 of wooden goods, 12 tannings and currying establishments, 7 flour mills, 7 saw mills, and 1 planing mill. Capital, Woodfield. XII. A. S. W. county of Indiana, watered by White river and its branches; area, 420 sq. m.; pop. in 1870, 14,168. The surface is hilly, and the soil fertile. The Louisville, New Albany, and Western railroad passes through it. The chief productions in 1870 were 130,043 bushels of wheat, 454,275 of Indian corn, 193,415 of oats, 42,146 of potatoes, 15,947 lbs. of tobacco, 49,798 of wool, 259,076 of butter, and 7,911 tons of hay. There were 4,612 horses, 3,451 milk cows, 6,656 other cattle, 18,273 sheep, and 18,614 swine; 9 manufactures of carriages, 1 of wagon material, 1 of agricultural implements, 2 of woolen goods, 1 planing mill, 12 saw mills, 6 tanneries, 3 currying establishments, and 5 flour mills. Capital, Bloomington. XIII. A. S. W. county of Illinois, bounded E. by the Kaskaskia river, and W. by the Mississippi; area, 360 sq. m.; pop. in 1870, 12,982. The surface is moderately uneven, and the soil is fertile. The chief productions in 1870 were 651,797 bushels of wheat, 548,718 of Indian corn, 182,451 of oats, 67,119 of swine, 103,968 of butter, and 5,243 tons of hay. There were 4,205 horses, 2,715 milk cows, 1,616 other cattle, 2,020 sheep, and 13,286 swine; 6 manufactures of saddlery and harness, 1 brewery, and 7 flour mills. Capital, Waterloo. XIV. A. S. E. county of Michigan, bordering on Lake Erie and Ohio; area, 540 sq. m.; pop. in 1870, 27,483. Huron river forms the N. E. boundary, and it is intersected by Raisin river. The surface is level and diversified by prairies and woodlands. The valley of Raisin river is celebrated for fertility and beauty. The county is traversed by the Flint and Pere Marquette and the Lake Shore and Michigan Southern railroads. The chief productions in 1870 were 249,086 bushels of wheat, 399,583 of Indian corn, 260,913 of oats, 268,373 of potatoes, 154,421 lbs. of wool, 894,265 of butter, and 44,896 tons of hay. There were 7,601 horses, 7,982 milk cows, 8,776 other cattle, 38,932 sheep, and 13,677 swine; 5 manufactures of agricultural implements, 10 of brick, 23 of carriages and wagons, 1 of tobacco and snuff, 8 flour mills, 10 tanneries, 33 saw mills, and 2 distilleries. Capital, Monroe. XV. A. S. W. county of Wisconsin, watered by the La Crosse, Lemonweir, and Kickapoo rivers and other streams; area, 900 sq. m.; pop. in 1870, 16,550. The surface is undulating or broken, and the soil fertile. It is traversed by the Chicago, Milwaukee, and St. Paul, and the West Wisconsin railroads. The chief productions in 1870 were 478,447 bushels of wheat, 188,119 of Indian corn, 291,469 of oats, 91,836 of potatoes, 479,209 lbs. of hops, 39,228 of wool, 391,476 of butter, and 29,312 tons of hay. There were 3,292 horses, 4,021 milk cows, 6,358 other cattle, 12,941 sheep, and 6,413 swine; 5 manufactures of carriages and wagons, 2 of clothing, 8 of cooperage, 2 of machinery, 1 of wrapping paper, 3 of saddlery and harness,
1 of woolens, 14 saw mills, and 8 flour mills. Capital, Sparta. A S. county of Iowa, drained by several creeks; area, 430 sq. m.; pop. in 1870, 12,724. The surface is diversified, occupied partly by prairies, and the soil is fertile. The Burlington and Missouri River railroad and the Central railroad of Iowa pass through it. The chief productions in 1870 were 159,815 bushels of wheat, 754,692 of Indian corn, 165,175 of oats, 64,073 of potatoes, 72,092 lbs. of wool, 292,452 of butter, and 21,206 tons of hay. There were 5,122 horses, 4,687 milch cows, 9,571 other cattle, 21,168 sheep, and 21,739 swine; 1 woolen, 4 flour, and 6 saw mills. Capital, Albia. A N. E. county of Missouri, watered by Salt river and its branches; area, 744 sq. m.; pop. in 1870, 17,149, of whom 2,005 were colored. The surface consists in part of rich undulating prairies. The county abounds in coal, lime stone, and freestone. It is traversed by the Hannibal and Moberly division of the To ledo, Wabash, and Western railroad. The chief productions in 1870 were 104,066 bushels of wheat, 589,127 of Indian corn, 304,375 of oats, 187,091 lbs. of tobacco, 68,772 of wool, 245,975 of butter, and 12,635 tons of hay. There were 9,765 horses, 2,989 mules and asses, 5,813 milch cows, 13,345 other cattle, 25,583 sheep, and 30,320 swine. Capital, Paris. MONROE, a city and the county seat of Monroe co., Michigan, situated on both banks of the river Raisin, 2 m. above its entrance into Lake Erie, with which it is connected by a ship canal, and on the Michigan Southern, the Flint and Pere Marquette, and the Canada Southern railroads, 22 m. S. W. of Detroit; pop. in 1850, 2,813; in 1860, 3,892; in 1870, 5,086; in 1874, 5,782. The harbor is good, and is protected by points of land jutting out from the river. The surrounding country is fertile. The city has many substantial brick blocks, handsome residences, and fine shade trees, and a park has been laid out in the centre of the business portion. The river affords excellent water power, and there are several foundries and machine shops, wagon and carriage shops, three grist mills, two saw mills, two plaster mills, three sawh, door, and blind factories, a cabinet and furniture factory, a paper mill, &c. There are four extensive nurseries, and 156 acres of land in vineyards. Near the city is a deposit of sand from which large quantities are shipped to Pittsburgh, Wheeling, and other points, for the manufacture of glass. Monroe is the seat of a young ladies' collegiate institute, established in 1851, and having in 1873-74 8 instructors, 109 students, and a library of 1,200 volumes. There are a national bank, three Roman Catholic and three Lutheran schools, a union school, several ward schools, two weekly newspapers, and seven churches. The first permanent settlement here was made by a small party of Canadians in 1784, who called the place Frenchtown. The first American settlement was probably made about 1798. In 1813 it was the scene of the massacre of several hundred American prisoners by the Indian allies of the British. It began to grow after the close of the war of 1812, and its name was changed in honor of President Monroe. MONROE, James, fifth president of the United States, born in Westmoreland co., Va., April 28, 1758, died in New York, July 4, 1831. His father was Spence Monroe, a planter, descended from Capt. Monroe, an officer in the army of Charles I., who emigrated with other cavaliers to Virginia in 1652. He was educated at William and Mary college, which he left in 1776 to enter the army as a cadet. Soon afterward he was commissioned lieutenant, and took an active part in the campaign on the Hudson. In the attack on Trenton, at the head of a small detachment, he captured one of the British batteries. On this occasion he received a ball in the shoulder, and was promoted to a captaincy. As aide-de-campus to Lord Stirling, with the rank of major, he served in the campaigns of 1777 and 1778, and distinguished himself in the battles of Brandywine, Germantown, and Monmouth. By accepting the place of aide to Lord Stirling he lost his rank in the regular line. Failing in his efforts to reenter the army as a commissioned officer, he returned to Virginia and began to study law under the direction of Thomas Jefferson, then governor of the state. When the British appeared soon afterward in Virginia, Monroe exerted himself in organizing the militia of the lower counties; and when the enemy proceeded southward, Jefferson sent him as military commissioneer to the army in South Carolina. In 1782 he was elected to the assembly of Virginia from the county of King George, and was appointed by that body, although but 23 years of age, a member of the executive council. In 1788 he was chosen a delegate to congress for three years, and took his seat on Dec. 13. Convinced that it was impossible to govern the country under the old articles of confederation, he advocated an extension of the powers of congress, and in 1785 moved to invest that body with authority to regulate trade between the states. The resolution was referred to a committee of which he was chairman, and a report was made in favor of the measure. This led to the convention at Annapolis, and the subsequent adoption of the federal constitution. Monroe also exerted himself in devising a system for the settlement of the public lands, and was appointed a member of the commission to decide upon the boundary between Massachusetts and New York. He strongly opposed the relinquishment of the right to navigate the Mississippi river, demanded by Spain. In 1785 he married a daughter of Lawrence Kortright of New York, a lady celebrated for her beauty and accomplishments. Having served out his term, and being ineligible for the next three years, Monroe settled in Frederickburg, Va. In 1787 he was reflected to the general assembly, and in 1788 was chosen a delegate to the
Virginia convention to decide upon the adoption of the federal constitution. He was one of the minority who opposed the instrument as submitted, being apprehensive that without amendment it would confer too much power upon the general government. The course of the minority in convention was approved by the great mass of the people of Virginia, and Monroe was chosen United States senator in 1790. In the senate he became a prominent representative of the anti-federal party, and acted with it till his term expired in 1794. In May of that year he received the appointment of minister plenipotentiary to France, and was received in Paris with enthusiastic demonstrations of respect. His marked exhibition of sympathy with the French republic displeased the administration. John Jay had been sent to negotiate a treaty with England, and the course pursued by Monroe was considered injudicious and reprehensible, as tending to throw serious obstacles in the way of the proposed negotiations. On the conclusion of the treaty, his alleged failure to present it in its true character to the French government excited anew the displeasure of the cabinet; and in August, 1796, he was recalled, under an informal concern. On his return to America he published a "View of the Conduct of the Executive in the Foreign Affairs of the United States" (Philadelphia, 1798), which widened the breach between him and the administration; but Monroe remained upon good terms with both Washington and Jay. He was governor of Virginia from 1799 to 1803, and at the close of his term was appointed envoy extraordinary to the French government to negotiate, in conjunction with the resident minister, Mr. Livingston, for the purchase of Louisiana, a right of deposit for the United States on the Mississippi. Within a fortnight after his arrival in Paris the ministers secured for $15,000,000 the entire "territory of Orleans" and "district of Louisiana." In the same year he was commissioned minister plenipotentiary to England, and endeavored to conclude a convention for the protection of neutral rights, and against the impressment of seamen. In the midst of these negotiations he was directed to proceed to Madrid, as minister extraordinary and plenipotentiary, to adjust the controversy between the United States and Spain in relation to the boundaries of the new purchase of Louisiana. In this he failed, and in 1808 he was recalled to England to act with Mr. Pinkney in further negotiation for the protection of neutral rights. On the last day of that year a treaty was concluded, but because of the omission of any provision against the impressment of seamen, and its ambiguity in relation to the other great points, the president sent it back for revival. All efforts to attain this failed, and Monroe returned to America. The time was approaching for the election of president, and a considerable body of the republican party had brought forward Monroe as their candidate; but the preference of the president for Madison was well known. Monroe believed that the rejection of the treaty, and the predilection expressed for his rival, indicated personal hostility on the part of Mr. Jefferson, and a correspondence on the subject ensued. Jefferson candidly explained his course, and showed that his preference for Madison was solely based upon solicitude for the success of the party, the great majority of which had declared in his favor. The misunderstanding terminated, and Monroe withdrew from the canvass. In 1810 he was again elected to the general assembly of Virginia, and in 1811 governor of the commonwealth. In the same year he was appointed by President Madison secretary of state, and after the capture of Washington in 1814 he was appointed to the war department, which he took without relinquishing the former post. He found the treasury exhausted and the public credit at the lowest ebb; but he set about the task of infusing order and efficiency into the departments under his charge, and proposed an increase of 40,000 men in the army, by levying recruits throughout the whole country. His attention was also directed to the defense of New Orleans; and finding the public credit completely prostrated, he pledged his private means as subsidiary to the credit of the government, and enabled the city to successfully oppose the forces of the enemy. He was the confidential adviser of President Madison in the measures for the reestablishment of public credit and the regulation of the foreign relations of the United States, and continued to serve as secretary of state to the end of Madison's administration, in 1817. In that year he succeeded to the presidency, by an electoral vote of 188 out of 217, as the candidate of the party generally known as democratic republicans. His cabinet was as follows: John Quincy Adams of Massachusetts, secretary of state; William H. Crawford of Georgia, secretary of the treasury; John C. Calhoun of South Carolina, secretary of war; Benjamin W. CromptoN of Massachusetts, secretary of the navy; William Wirt of Virginia, attorney general. Calhoun and Wirt were not appointed until December, 1817. On Nov. 30, 1818, Secretary Crompton was succeeded by Smith Thompson of New York, who on Dec. 9, 1823, was succeeded by Samuel L. Southard of New Jersey. Soon after his inauguration, President Monroe made a tour through the middle and eastern states, during which he thoroughly inspected arsenals, naval docks, fortifications, and garrisons; reviewed military companies, corrected public abuses, and studied the capabilities of the country with reference to future hostilities. On this tour he wore the undress uniform of a continental officer. In every point of view the journey was auspicious. Party lines seemed about to disappear, and the country to return to its long past state of union. The president was not backward in his assurances of a strong de-
sire on his part that such should be the case. The course of the administration was in conformity with these assurances, and secured the support of an overwhelming majority of the people. The great body of recommendations in the president's message were approved by large majorities. The tone of debate was far more moderate; few of the bitter criminations which had been the fashion in the past were uttered; and the period became known as "the era of good feeling." Among the important events of the first term of President Monroe were the admission into the Union of the states of Mississippi, Illinois, and Maine. In 1818 a convention was concluded between Great Britain and the United States in relation to the Newfoundland fisheries, the restoration of slaves, and other subjects; and in 1819 Spain ceded to the United States her possessions in East and West Florida, with the adjacent islands. In 1820 Monroe was reelected president almost unanimously, receiving 251 out of 292 electoral votes. On Aug. 10, 1821, Missouri became one of the states of the Union, after prolonged and exciting debates, resulting in the celebrated "Missouri compromise," by which slavery was permitted in Missouri, but for ever prohibited elsewhere N. of the parallel of 36° 30'. Other events of public importance during the second term of President Monroe were the recognition in 1822 of the independence of Mexico, and the provinces in South America formerly under the dominion of Spain; and the promulgation, in his message of Dec. 2, 1828, of the policy of neither entangling ourselves in the broils of Europe, nor suffering the powers of the old world to interfere with the affairs of the new, now generally known as the "Monroe doctrine." On this occasion the president declared that any attempt on the part of the European powers to "extend their system to any portion of this hemisphere" would be regarded by the United States as "dangerous to our peace and safety," and would accordingly be opposed. On March 4, 1825, Monroe retired from office, and returned to his residence of Oak Hill, in Loudon co., Va. He was chosen a justice of the peace, and as such sat in the county court. In 1829 he became a member of the Virginia convention to revise the old constitution, and was chosen to preside over the deliberations of that body; but he was compelled by ill health to resign his post in the convention, and to return to Oak Hill. Pecuniary embarrassment was added to bodily infirmity, and although he had received $350,000 for his public services, he was in his old age harassed by debt. His wife died in 1890, and in the summer of that year he removed to the residence of his son-in-law, Samuel L. Gouverneur, in the city of New York, where he died. In 1858 his remains were removed with great pomp to Richmond, Va., and reinterred on July 5 in the Hollywood cemetery.—Monroe held the reins of government at an important period, and administered it with prudence, discretion, and a single eye to the general welfare. He went further than any of his predecessors in developing the resources of the country. He encouraged the army, increased the navy, augmented the national defences, protected commerce, approved of the United States bank, and infused vigor and efficiency into every department of the public service. His honesty, good faith, and simplicity were generally acknowledged, and disarmed the political rancor of his strongest opponents. Madison thought the country had never fully appreciated the robust understanding of Monroe. This may be partially accounted for by the fact that he never acquired distinction in oratory. In person, Monroe was tall and well formed, with a light complexion and blue eyes. The expression of his countenance was an accurate index of his simplicity, benevolence, and integrity.

Mons (Flem. Bergen), a fortified city of Belgium, capital of the province of Hainaut, on the river Trouille, 52 m. S. S. W. of Brussels; pop. in 1871, 27,764. It communicates with the Scheldt by the canal of Mons, and is connected by railways with Brussels, Namur, and Valenciennes. The E. side is protected by two large ponds, and the surrounding country may be flooded by admitting the river Trouille. The walls are in the form of a polygon, and have five gates and 14 bastions. The principal church is that of St. Wandrus (Walrudes), a fine Gothic edifice begun in 1460. Among other principal public buildings are the castle, the Gothic town hall, court house, theatre, arsenal, and military hospital. The town contains also a college, which in 1873 had 252 students, a school of art, a public library, and a society of art and science. There are several salt and sugar refineries. In the vicinity are coal mines which give employment to more than 25,000 persons. The coal basin in which the city is situated is called the Borinage, and the miners Borains. In coal, flax, hemp, grain, timber, horses, cattle, and manufactures an active trade is carried on.

Monsigneur (Fr. mon, my, and seigneur, lord), a French title once applied to saints, and subsequently to princes, nobles, certain high dignitaries of the church, and other titled personages. Under the monarchy the dauphin's eldest son was styled Monsignore, without any addition. The title is now given only to prelates. The Italian monsignore has a similar signification.

Monserrat, or Monserrat, a mountain in Catalonia, Spain, on the right bank of the river Llobregat, in the province and about 25 m. N. W. of the city of Barcelona. It is about 24 m. in circumference, and its summit consists of several jagged serrated peaks, the highest of which is 4,057 ft. above the sea. Far up the E. side stands the monastery of the same name, which owes its origin to an image of the Virgin, said to have been made by the apostle Luke and brought to Barcelona in A. D. 50 by
the apostle Peter. At the time of the Moorish invasion it was hidden in the hill, but was discovered in 880, and on a spot indicated, as was asserted, by the image, a chapel was built over it. A convent was founded, which was converted into a Benedictine monastery in 976. The chapel which now contains the image was founded in 1592. The monastery was suppressed in 1835, but some of the monks were allowed to remain. Several fortifications were made on this mountain during the peninsular war, as the high road from Manresa across the Llobregat traverses it. There is a multitude of shrines and hermitages. About 60,000 pilgrims and tourists annually visit the convent, and during the fête of the Virgin in September railway trains and omnibuses run continually from Barcelona.

**MONSIEUR** (Fr. mon, my, and sieur, sir), a French title of gentlemen, parallel in its original significance and use to the female title **madame.** Under the monarchy it was applied without the addition of the name to the king’s eldest brother. It is now given to Frenchmen of every rank and condition. During the first revolution, and for brief periods in 1839 and 1848, **monsieur** was replaced by **citoyen,** citizen.

**MONSOON** (Arab. mausum, season, corrupted by the Portuguese into monção), an intertropical wind which blows part of the year from one point of the compass, and the remainder of the year in a contrary direction. These winds are more particularly known in the seas adjoining the great Asiatic continent and archipelago, including Papua and the N. part of Australia, whence they extend to about lon. 160° E. The causes which produce them are, in theory, the same as those generally supposed to cause the trade winds. When the sun is in N. latitude and comes over a large portion of Arabia, Hindostan, Burmah, and Cochín China, these lands become heated to a much higher temperature than the surrounding equatorial sea and atmosphere, the cooler air flows toward these regions; and as they have less rotary velocity than the latitudes bordering upon the equator whence the current comes, it acquires a relative N. E. direction in passing to the north, and is called the S. W. monsoon. In the northern hemisphere, when the land is cooled by the sun being in S. latitude, the regular N. E. trade wind prevails throughout these seas, and what is called the N. E. monsoon is in reality the N. E. trade wind. South of the equator the S. E. trade wind continues to blow over all that part of the ocean which has not large tracts of land to the south; but where this is the case, as in the Java seas, and as far E. as New Ireland, we find the same causes operating again, and a N. W. monsoon taking the place of the regular S. E. trade wind when the sun has southern declination. These general laws, with trifling exceptions, apply to all monsoons; that is to say, when the S. W. monsoon blows N. of the equator, the wind blows from S. E. in the regions S. of the equator; and when the N. W. monsoon prevails in S. latitude, the wind blows from N. E. in N. latitude. **MONSTER,** a term limited by Isidore Geoffroy Saint-Hilaire to the complex and grave congenital anomalies of conformation, disagreeable to the sight, rendering difficult or impossible the accomplishment of certain functions, and producing a disposition of organs very different from that ordinarily presented by the species, whether animal or vegetable, involving change in the form, structure, volume, position, and number of parts. This definition excludes simple vices of conformation, such as bare lip, club foot, fissured palate, gigantic and dwarfed stature, albinism, and hermaphroditism. The phenomena of monstrosity were not examined in a philosophical spirit until the early part of the present century, when the sciences of comparative anatomy and embryology could be brought to their explanation; the principal workers in the field at this period were the elder Geoffroy Saint-Hilaire, Serres, and Meeckel. The history of monsters, or teratology, is a science in itself. In the fabulous period of this science, ending about the beginning of the 18th century, monsters were regarded as exhibitions of the creative power of God, as proofs of his anger and the signs of some approaching public calamity, or as the work of demons; and as such, by the old Greek and Roman laws, they were at once put to death; even as late as the 17th century they were either destroyed or shut up from human sight. In the first half of the 18th century the causes of monstrosity were zealously sought for, and from the time of Haller the science made rapid progress.—Many forms of monstrosity are embryonic conditions rendered permanent beyond the normal period, thus forming series comparable to those of the fœtus and to zoological divisions of animals; others seem to be formed by excess of growth, according to the theories of original excess of productive power or eccentric development of the vascular system; double monsters, whether partial or complete, are united by homologous surfaces, side to side, back to back, or face to face, each internal organ of one having a corresponding organ in the other; and the laws regulating monstrosities, whether by excess or defect, are intimately connected with those presiding over normal organizations. It is true, as Geoffroy says, that "it is in her monstrosities that nature reveals to us her secrets," Isidore Geoffroy Saint-Hilaire (Histoire des anomalies, &c., 3 vols. 8vo, Paris, 1832-6) makes the two classes of single and compound monsters, which he divides into orders, tribes, families, and genera on the Linnaean zoological plan; in the first class he places all such as have the elements of only a single individual, and in the second those which have the parts, complete or incomplete, of two or more individuals. In the first class he makes three orders: A. **Autautes,** or such as are capable of sustaining life, sometimes extra-uterine, by
their own organs, having a heart, lungs, almost all the digestive organs, and a portion at least of the head, most of the body remaining symmetrical and nearly normal. This order contains four subdivisions or tribes: I., in which the limbs are modified by deficient development or by fusion, or are absent; II., in which the viscera of the trunk are more or less seriously displaced and external, the limbs normal, incapable of extra-uterine life; III., in which the principal anomalies are in the cranium and brain, the modifications of the face and limbs being of secondary importance; the brain is deformed, incomplete, partially or wholly outside the cranial cavity, or even entirely absent, with corresponding deficiency in the arch of the skull; this includes an extensive series both in man and animals, among others the so-called anencephalous fetuses, all incapable of life beyond a few hours or perhaps days; in some the spinal canal is largely open, and the spinal cord as well as the brain absent; IV., in which the face is more deformed than the cranium, the nasal apparatus being atrophied or displaced, bringing the eyes near together, or the central region of the face so deficient that the ears are joined on the median line; this includes the one-eyed monsters, like the fabulous Polyphemus, and rhinecephalous fetuses; all these die speedily from the imperfection of the brain. B. Omphalosites, living a merely vegetative life ceasing with the separation from the parent, many of the organs being absent and the existing ones very imperfect with abnormal and unsymmetrical forms; these include the parencephalous and acaephalous fetuses, the former having some traces of cranium, but no heart sufficient to circulate blood, and the latter destitute of head except the merest rudiments, often having neither neck nor chest, and but few of the abdominal organs; they never reach the full term of gestation. C. Parasites, including the imperfect products of conception commonly called moles; they are irreparable; divided principally of bones, teeth, hairs, and fat, having no umbilical cord, and implanted directly on the parent organs, where they live a vegetative and parasitic life; in most cases these appear to be a deformed and abnormally developed placenta, with a few remains of the prematurely dead embryo; they have been found attached to the uteruses and ovaries, and the gestation has usually been much prolonged, even to years, some of the second teeth having been seen in their substance.—In the second class, or that of compound monsters, the double ones he divides into autostuaires, in which the two individuals present the same degree of development, each having an equal share in the life common to both, a union of two autostuaires; and parasito- taires, composed of two very unequal or dissimilar individuals, one complete and the other imperfect, and the latter capable of living only at the expense of the former. The tribes of the autostuaires are: I. That in which the individuals are united only in a single region, the duplicity being complete in every other part. This tribe is naturally subdivided into two families, according as the umbilicus is double or single; in the former belong the double monsters united by any portion of the trunk or head, like the famous Hungarian sisters, Helen and Judith, joined back to back by the thighs and loins; these were born in 1701, and lived to their 22d year; they had neither the same temperament nor character; and Helen was larger, better looking, more active, intelligent, and gentle than her sister; they were very fond of each other, performed some physiological acts in common and others separately, and were sick and died together. Two black children, called the Carolina sisters, Christina and Millie, united by the lower part of the backs, have been exhibited in various parts of this country and Europe; in 1869, when they were 18 years old, they were apparently in perfect health. A full description of them is given in the "Boston Medical and Surgical Journal" for July 8, 1869, from which it appears that the hips are so far separated that on one side two fingers can be passed in between them, there being only a crease on the other side. The call to evacuate the bowels and bladder is simultaneous, and the intestines must therefore unite not far above their termination; there is a single anus and rectum between the anterior limbs, and the two thorval orifices and vagina open into a common vulva. The maimmary development is good, though the breasts are considerably deformed from spinal curvature; menstruation is regular. If hunger and thirst be felt in both at the same time, it must be through nervous connections. They are two individuals, psychologically, morally, and legally; one may be awake and the other asleep; their general health is good, the weight being 170 lbs., about equally divided between them; their expression is cheerful, manners agreeable, and intelligence above the average; they sing together with good effect. They are inclined to rest on the back legs, and walk upon these, or upon all four, moving sidewise; the front legs are a little the shortest, from the elevation of the front hips from spinal curvature; they can walk rapidly, and even waltz. They are united by the sacrum, and probably by the lower lumbar vertebrae; both feel a touch upon the lower limbs, indicating that the sensory nerves, from the posterior columns, mingle at the lower part of the spine; but the motor nerves, from the anterior columns, are so distinct that one cannot move the limbs of the other. (See Annales d'hygiène publique, Paris, April, 1874.) To the family with a single umbilicus belong such as are joined in the hypogastric and sternal regions, front and sides of thorax, and sometimes even by the bones and jaws. Among those united by the xiphoid region of the sternum were the Siamese twin brothers, Chang and Eng, having a single um-
biliens in the centre of the moderate-sized connecting process. They were born in 1811, were exhibited in most parts of Europe and the United States, and died, within a few hours of each other, in North Carolina, Jan. 17, 1874; each was married, and had several children, none of whom were monsters. They were physiologically distinct, having different forms, strength, tastes, and dispositions; their physical functions were performed separately; the sickness of one did not affect the other; hence there could not have been any free interchange of circulations. In the connecting ensiform cartilage, the post-mortem examination showed that the band contained four peritoneal pouches, two of which met and overlapped on the median line, and that their livers and hepatic vessels communicated, though not freely, indicating that any attempt during life to separate them would probably have proved fatal; whether, had there been time and opportunity, the separation of the living from the dead would have been fatal, may admit of doubt. Chang died first, probably of cerebral clot, during the night; when Eng awoke and found his brother dead, his fright and the consequent nervous shock, acting on an enfeebled heart, produced a fatal syncope. There was a region of common sensibility in the median line of the band. Though these lived to the age of 63 years, in the last named members of the group the anomaly is generally incompatible with extra-uterine life. Tribe II. comprises monsters in which the individuals are distinct at the pelvic extremity, but connected in the head and sometimes in the whole supra-umbilical region. In one family the bodies are united from the umbilicus upward, with the head more or less completely double, in some with the two faces directly opposite; as far as known, this deformity is incompatible with life. In another family the trunks are joined above the umbilicus, with a single head bearing but few marks of duplicity, and with two or four thoracic limbs; both these families occur in man, but the latter very rarely. Tribe III. includes such as have the head double, but the trunks more or less united into a single body and two lower extremities; sometimes the bodies are distinct from the umbilicus upward, with generally a rudimentary third lower limb; in others the heads are united behind, but show two faces in front. In the parasitaire the smaller and less perfect individual may be attached near the umbilicus, or very far from it, and may be reduced to a mere head without body; in some cases the monster shows a single body, with supernumerary jaws, portions of the head, or extremities; and in the least perfect of all the accessory growth is included within the principal body. The parasitic growth, from its small size, does not interfere with the birth, and such monsters have not only lived to be adults, but have become parents of well formed offspring. Most authors deny the existence of triple monsters, but Geoffroy Saint-Hilaire admits it, regarding the quadruple and quintuple cases as fabulous.—Considering the whole number of births, monstrosities are rare; after man they are most common in the hog, ox, cat, sheep, dog, and chick. Many, if not most, monsters give no indication of anomalous formation in the course of gestation, and they are most frequently born of mothers in good health and who have previously had normal children; females which bring forth twins have been found most liable to produce monsters, the separate amnions of each from contiguity favoring the confusion or blending of parts; the birth is usually premature, though sometimes long after the natural time. The hereditary transmission of monstrosity is very rare, even when the reproductive functions are unimpaired. The female sex seems to predominate, taking the whole range of monsters. Monstrosity is more common and extraordinary in the vegetable than in the animal kingdom, from the easier disengagement and displacement of parts; yet even here it is subject to and explicable by the laws of normal vegetable growth; some botanists consider double flowers and other similar products arising from peculiar culture as monsters, and
MONSTRELET

such as these are perpetuated by seed. Monstrosity may be due to an absence of formation; to an arrest of development, an embryonic structure remaining permanent; to an excess of development; and to a union of parts, more or less normal, belonging to different individuals. Prof. J. Wyman ("Proceedings of the Boston Society of Natural History," 1867), in a paper on symmetry and homology in limbs, draws attention to the analogy between symmetry and polarity, illustrating his remarks by figures; he thus explains both normal and abnormal development, and the various kinds of double monsters. Though it is impossible to admit the action of slight causes, of momentary continuance, popularly believed to be connected with monstrous or imitative growths, still the artificial production of variously deformed and imperfect chicks by the shaking, or malposition, or unnatural treatment of eggs, shows that appreciable external causes may occasionally be satisfactorily traced; it is now generally conceded that prolonged unfavorable circumstances during pregnancy may lead to monstrous growths. See the works quoted by Geoffrey Saint-Hilaire, and the papers of G. J. Fisher, M. D., in the "Transactions of the New York Medical Society" (1865-8). (See Teratology.)

MONSTRELET, Enguerrand de, a French chronicler, born in Cambrai about 1390, died July 20, 1453. He filled several offices in Cambrai, being bailiff of the chapter, provost of the city, and bailiff of Walloncourt. His chronicle is in two books, extends from 1400 to 1444, and comprises an account of the capture of Paris and the conquest of the French monarchy by Henry V., and of the wars which resulted in the expulsion of the English from most parts of France. His style has none of the animation and picturesque ness of Froissart, but it is marked by dignity, simplicity, and accuracy. The latest edition is that of L. Douet-d'Arcq (6 vols. 8vo, Paris, 1857-62). The best English version is by the Rev. Thomas Johnes (13 vols. 8vo, London, 1810). Appended to the earlier editions of Monstrelet are two spurious books continuing the history to 1467.

MONTAGUE, Basil, an English lawyer, born in London, April 24, 1770, died in Boulogne, Nov. 27, 1851. He was a natural son of John Montagu, fourth earl of Sandwich, and Miss Ray, who was shot in 1779 at Covent Garden by the Rev. James Hackman, a frantic admirer. Basil graduated at Cambridge, was called to the bar in 1798, and acquired a large practice in cases of bankruptcy. He formed an intimacy with that literary circle of which Coleridge was a leader, and became a convert to the political theories of Godwin. In 1806 Lord Chancellor Erskine made him a commissioner of bankrupts. Impressed with the evils of the law administered in his court, he published a yearly detail of its pernicious results, and ultimately induced its amelioration. Under the new law Mr. Montagu was appointed accountant general, in which capacity he com-
pelled the bank of England to pay interest (never previously demanded) on the moneys that had been deposited there by his court. He published 40 volumes, including several against capital punishment, and left, it is said, 100 volumes in manuscript. His principal professional work is "A Digest of the Bankrupt Laws" (4 vols. 8vo, London, 1805), of which several editions have been published. Of his editorial works the most important is his edition of "The Works of Francis Bacon" (16 vols. 8vo, 1826-34), the last volume of which contains a "Life of Bacon" by the editor.

MONTAGUE, Edward Wortley, an English author, born at Wharncliffe, Yorkshire, in October, 1713, died in Padua, May 2, 1776. He was the only son of Edward Wortley and Lady Mary Wortley Montagu. He ran away from school, and went as a cabin boy to Spain, whence he was sent back to England by a British consul. He was next committed to the charge of a private tutor, and sent to travel on the continent. On returning to England he married a woman in very humble life, almost old enough to be his mother, lived with her but a few weeks, and then abandoned her. In 1747 he was returned to parliament for Huntingdonshire, but soon became so involved in debt that he had to resign. He went to France, and thence to Italy, where he became a convert to the Roman Catholic church; and from Italy to Egypt, where he turned Mohammedan. He was returning to England when he died. He published "Reflections on the Rise and Fall of the Ancient Republics," the authorship of which was claimed by his tutor, Mr. Foster. His "Autobiography" was published in 1869 (3 vols. 8vo, London).

MONTAGU, Elizabeth, an English authoress, born in York, Oct. 2, 1720, died in London, Aug. 25, 1800. She was the daughter of a Mr. Robinson of Horton in Kent. In 1742 she married Edward Montagu, a grandson of the first earl of Sandwich, who died in 1775, leaving her a large fortune. She made her house a favorite resort for literary characters, and one of the principal places of meeting of the blue stocking club. For many years she gave annual dinners on May day to the chimney sweeps of London. She was the author of three "Dialogues of the Dead," published with Lord Lyttleton's (1760), and wrote an "Essay on the Genius and Writings of Shakespeare" (1769), in refutation of the criticisms of Voltaire. Her epistolary correspondence was published by her nephew, Matthew Montagu (2 vols., 1809). See also her life as illustrated by her correspondence in "A Lady of the Last Century," by Dr. John Doran (London, 1872).

MONTAGU, Lady Mary Wortley, an English authoress, eldest daughter of Evelyn Pierrepont, duke of Kingston, born at Thoresby, Nottinghamshire, about 1690, died Aug. 21, 1762. She was related through her father to Beaumont the dramatist, and through her mother to Fielding the novelist, who was her second
cousin. Her beauty and wit made her the pet of her father, and she acquired the elements of Greek, Latin, and French under the tuition of her brother's preceptors. At the age of 12 she wrote a poetical epistle from Julia to Ovid; at 15 she was meditating the establishment of an English nunnery, and was correcting her education by extensive reading; at 20 she made a translation of the Enchiridion of Epictetus. Meantime she lived principally at Thoresby and at Acton, near London, and as the eldest daughter of a widower presided at the dinner table and exerted her social powers in the entertainment of guests. In 1712 she was privately married to Edward Wortley Montagu. A disagreement concerning the settlements had caused the duke of Kingston to withhold his consent, and the union did not prove happy. They lived in the country till after the accession of George I. in 1714, when Mr. Montagu joined the ministry as one of the lords of the treasury. Lady Mary, on her first appearance at St. James's, was hailed with universal admiration, as much for her conversation as for her beauty. In 1716 she accompanied her husband to Constantinople, whither he was sent as ambassador to the Porte as consul general in the Levant. Her letters descriptive of the court and society of Vienna, and the scenery and customs of the East, which rank among the choicest publications of their class, were published surreptitiously after her death (3 vols., 1763), under circumstances which afforded no guarantee for their authenticity; this, however, is in general proved by the coincidences of style with her other writings, though the text has been tampered with and spurious letters introduced; a fourth volume was published in 1767. At Belgrade she first observed the practice of inoculation for the smallpox, by which malady she had lost an only brother and her own fine eyelashes. In 1718 she applied the process after earnest examination to her son and daughter; and on her return to England the experiment was tried at her suggestion on five persons under sentence of death. The success of the trial did not prevent the most violent clamors against the innovation. On returning to England she had taken up her residence at Twickenham, at the solicitation of Pope, who had been one of her most intimate correspondents. A rupture soon took place between them, according to her statement, because she could not refrain from laughter when at an ill-chosen moment he was solemnly and passionately making love to her; and from that time he treated her with constant malice. She wrote many witty verses. In 1739 her health was declining in consequence of a cancer which ultimately proved fatal, and she went abroad. She took up her abode in a deserted palace on the shores of Lake Iseo, in Lombardy, and afterward in the city of Venice, where she was residing when her husband died in 1761. She then returned to England, and died within a year. The best edition of her "Letters and Works" (3 vols., London, 1837), by her great-grandson Lord Wharncliffe, containing full biographical notices, was critically revised for Bohn's "Historical Library" by Moy Thomas (1861). Her letters were edited by Mrs. S. J. Hale (New York, 1856).

MONTAGUE, a n. county of Texas, separated from Indian territory by Red river; area, 900 sq. m.; pop. in 1870, 890, of whom 24 were colored. There are some good bottom lands on Red river. The chief productions in 1870 were 2,476 bushels of wheat, 41,715 of Indian corn, 4,933 of oats, and 21,200 lbs. of butter. There were 383 horses, 687 milch cows, 10,182 other cattle, and 5,093 swine.

MONTAGUE, Charles, earl of Halifax, a British statesman, born at Horton, Northamptonsire, April 16, 1661, died May 19, 1715. His father was a younger son of the earl of Manchester. Charles was destined for the church, and was sent to Trinity college, Cambridge. He wrote there in 1685 some verses on the death of King Charles II., and in 1687 joined Prior in the composition of a parody in prose and verse on Dryden's "The Hind and Panther" under the title of "The Hind and the Panther Transversed to the Story of the Country Mouse and the City Mouse." He signed in 1688 the invitation to the prince of Orange, was a member of the convention parliament, and soon afterward, having married the countess dowager of Manchester, gave up the church, and purchased the place of one of the clerks of the council. In 1690 he was again returned to the house of commons, where for some years his life was a series of triumphs. He was soon called to the treasury board and the privy council, and in 1694 was appointed chancellor of the exchequer, in reward for having devised the establishment of the bank of England, the plan of which had been proposed by William Patten, three years before, but not acted upon. Montague was the originator of the great recoinage act (1695), of exchequer bills (1696), and of the tax on windows. On May 1, 1697, he was made first lord of the treasury, and appointed one of the regency during the king's absence on the continent; but on the reorganization of the ministry in 1699 he was removed to the auditorship of the exchequer. In 1700 he was created Baron Halifax. In April, 1703, he was impeached by the commons, together with Portland, Oxford, and Somers, for advising the king to sign the partition treaties and for other alleged offences; but the prosecution was dropped. After the accession of Queen Anne he was accused by the lower house of breach of trust in his management of the public accounts while chancellor of the exchequer; but he again escaped by the protection of the house of lords. He proposed and negotiated the union with Scotland in 1707, and was one of the judges in Sacheverell's trial, when he voted for a mild sentence. On the death of the queen he acted as one of
the regents, and after the accession of George
I. (1714) was made earl of Halifax and first
commissioner of the treasury.

MONTAIGNE, Michel, seigneur de, a French
author, born at the château of Montaigne,
in Périgord, Feb. 28, 1533, died there, Sept.
13, 1592. His father was an eccentric feudal
baron. The young Montaigne was in his in-
fancy placed under a German tutor, who could
not speak French and was directed to confer
with his pupil only in the classical tongues.
The entire household and even the artizans
and peasants of the village learned Latin
phrases in order to address the youthful lord.
At the age of six he was able to converse in
Latin with ease, and his study of Greek had
been transformed into a game, which however
he never mastered. He was sent to the college
of Guienne at Bordeaux, and at 13 completed
the academical course. Love of liberty and
laziness were, he says, his predominating qual-
ities through life. He never perused his
accounts nor revised his manuscripts; wrote
so badly that often he could not read his own
hand; never touched a book except when he
was weary of doing nothing; had an amazing
ignorance of common things, which seemed
the greater in consequence of his defective
memory; could not remember the names of
his servants nor of the current coins; would
read a book as new which he had scribbled
over with notes a year before; would forget
his idea while on the way to the library to
record it; knew nothing about the agricultu-
ral implements, processes, and products amid
which he grew up; and could not swim, fence,
carve, guess a riddle, saddle a horse, nor make
a pen. He confesses that the only books of
solid learning he could ever seriously devote
himself to were Plutarch and Seneca. After
quitting the college of Guienne he began the
study of law, and at the age of 21 became a
counsellor in the parliament of Bordeaux, an
office from which he retired in 1570. There
began his friendship with Etienne de la Boëtie,
whom he had loved before meeting him, whose
early death he laments in one of the finest of
his essays, and whose works he edited. He
was inclined to an easy neutrality amid the re-
ligious and political conflicts of the time; made
frequent visits to court, where he was intimate
under successive monarchs; married at the age
of 33; and at the age of 38 retired to his châ-
teau. He soon after began the composition of
his Essais; the first edition appeared in
1590, and the work was several times enlarged
during his life. At his death he left two copi-
es of the edition of 1588 full of corrections
and additions, which were incorporated in the
work by Mlle. de Gournay and subsequent ed-
tors. Suffering from the stone and nephritic
colic, he sought relief by travel, and in 1580-
'81 visited Germany, Switzerland, and Italy.
The journal of his tour was discovered and
published at Paris in 1774, after being en-
tombed for nearly two centuries in the family
chest in the château of Montaigne. The hu-
mors of a valetudinarian seem to have chiefly
courted his attention. He gauges civiliza-
tion by the resources and the art of the kitch-
en. He passes through the scenes of classical
antiquity with scarcely a reference to any Ro-
man author. His vanity appears in his de-
tailed accounts of attentions received from the
great, and in his delusion of the burgomaster
of Augsburg into the belief that he and his
suite were a company of knights and barons.
Some of his descriptions, especially of what he
saw in Rome, are made with the aid of H. Motteau.
On his return he was elected mayor of Bor-
deaux, which office he held for four years,
maintaining peace in a time of disorder; and
after retiring to his domain in the very focus
of civil war, he refused to fortify his house,
leaving it "to the stars to guard," and after-
ward boasted that his bold frankness had con-
jured away all dangers from it. In 1588, while
in Paris superintending the publication of his
Essais, he was employed to mediate between
Henry of Navarre, afterward Henry IV., and
the duke of Guise. He left no sons, and by his will
authorized Charron to assume his family arms.
His Essais, to which alone he owes his reputa-
tion, profess to have been purely a work of
amusement. Informal and irregular, they offer
the first modern examples of essays or at-
ttempts in distinction from finished works. In
an age of pedants, Montaigne appeared as the
antagonist of literary conventionalism, and de-
defied the pretensions of erudition, and the
zealous treatment of every-day life, rich and vig-
orous language, easy and indulgent gayety,
genial egotism, and minute confessions, are
among the charms of his work. He employed
the language of Christianity, and both Catho-
lics and Protestants have claimed his sympa-
thies; yet a practical heathenism pervades his
philosophy. He was a kind of imperfect Soc-
rates, the cross-examiner of his generation,
taking nothing on trust, and hating pretense,
yet too careless and selfish, and not pure and
thorough enough, to give his ideas effect. A
monument to him was inaugurated in Bor-
deaux, Sept. 6, 1588.—The latest editions of the
Essais are one containing notes of all of the
commentators, collected by J. V. Le Clerc,
with a preface by Prévost-Paradol (2 vols.
5vo, Paris, 1865); one by Courbet and Royer
in Lemierre's new collection of great writers
(1872 et seq.); and one reprinted from the edi-
tion of 1588 with annotations by H. Motteau
and D. Jonast (4 vols., 1874-5). See also
Documents inédits sur Montaigne, by Payen
(4 vols., 1847-56), and Études sur les Essais de
Montaigne, by Alphonse Leveaux (1873).
They were several times translated into English,
and very frequently reprinted, in the 17th and 18th
centuries. A copy of Florio's translation (1609),
the only book known to have been owned by
Shakespeare, is in the British museum with
his autograph. One of the best biographies
of Montaigne is by Bayle St. John (London,
1857).
Montalant, Mle. See Damorze.

Montalembert. I. Marc René de, marquis, a French military engineer, born in Angouleme, July 13, 1714, died March 29, 1800. He was descended from an ancient family of Poitou, early entered the army, and took an active part in the campaigns of Italy and Flanders, and in 1741 in the war of the Austrian succession. He devoted himself to military science, in 1747 became a member of the academy of sciences, and established foundries for casting cannon. His innovations in the art of fortification were opposed by the French engineers, but all doubts were dispelled by his successful construction of the fort of Ré. He was also employed in the fortifications of Anklam, Stralsund, and the islands of Ax and Oléron. He became a partisan of the revolution, and relinquished his pension in favor of the national convention. During the reign of terror he obtained a divorce from his first wife, an actress and novelist, and married the daughter of an apothecary. He had given up to the government his foundries, without receiving any equivalent, and was involved in further difficulties by the publication of his works, his various experiments for the improvement of the military art, and the depreciation of paper money. He had also executed at his own expense and presented to the government various models relating to fortifications and artillery. His services as a military reformer were publicly acknowledged by the convention and by the council of 500, and some inadequate pecuniary relief was afforded him. He wrote on the campaign of 1757, on the siege of St. Jean d'Arc, and a historical essay on the founding of cannon, and contributed valuable memoirs to the academy. His great work, La fortification perpendiculaire, ou l'Art défensif supérieur à l'offensive (11 vols. 4to, Paris, 1776-90), with illustrations, absorbed a large portion of his fortune. His system of detached forts inaugurated a new era not only in fortification, but in the attack and defense of fortresses and in strategic science generally. His principles were adopted in the fortifications of Ehrenbreitstein, Cologne, Sebastopol, Cronstadt, and Cherbourg, in the batteries at the entrance of Portsmouth harbor, and in most modern forts for harbor defence. (See Fortification.) II. Charles Forbes René de, count, a French statesman, grandson of the preceding, born in London, May 29, 1810, died in Paris, March 13, 1870. He received his university education in Paris, and in his 19th year published a small work on Sweden. In 1850 he became the associate of Lamennais and Lacordaire in founding and editing L'Avenir, went with them to Rome to plead their own cause in 1831, and on his return opened, with Lacordaire and De Coux, a free Catholic school in Paris, which was closed by the police. The directors were arraigned before an inferior court for infringing the ordinances on public instruction; but Montalembert, having meanwhile become a member of the chamber of peers, transferred his case to that court, and delivered there in his own defence his first public speech. The papal censure which fell upon Lamennais a few years later strengthened Montalembert's attachment to the church, without shaking his liberal convictions. He devoted himself to the study of the middle ages, and published Histoire de Saint Elizabeth de Hongrie (Paris, 1836; English translation by Mary Hackett and Mrs. J. Sadlier, New York, 1854), and an essay Du Vandalisme et du Catholicisme dans l'art (1839). He spoke frequently in the chamber of peers. In 1842 he opposed M. Villedain's bill for the organization of secondary schools, protesting against the "university monopoly" which placed all the schools under the control of the faculty of lawmen. In 1849 he published his Manifeste catholique. He was now the recognized leader of the Catholic party. He delivered three elaborate addresses on the freedom of the church, of education, and of religious orders, in the last of which he eulogized the Jesuits; and in 1847 he founded a religious society to uphold the cause of the Swiss Sonderbund. He spoke in favor of Poland in 1831, 1844, and 1846. Early in 1848, in a speech on radicalism, he predicted a revolution in the course of three months. When it broke out he joined the democratic party, published an address urging republican sentiments, and was elected by the department of Doubs as a deputy in the constituent assembly. Here, however, he acted rather with the conservative party than with the thorough democrats. He opposed the admission of Louis Napoleon, and voted against the new constitution; and toward the close of the session he supported Dufaure's bill for the restriction of the press, and approved the expedition sent to Rome to restore the papal authority. Returned to the legislative assembly by the departments of Doubs and Côtes-du-Nord, he became still more radical, and was one of the committee which drafted the law of May 31, abolishing universal suffrage. In June, 1851, he had a memorable debate with Victor Hugo on the proposed revision of the constitution. After the coup d'etat of Dec. 2 he protested against the imprisonment of the deputies, and became more determined in his hostility to Napoleon; but he obtained a place on the second consultative committee, and a seat in the legislative body, where he was almost the only representative of the opposition. Having failed to be re-elected in 1857, he lived in retirement, employed in literary labors. An article which he published Oct. 25, 1858, entitled Un debat sur l'Ede au parlement anglais, led to his prosecution on account of invidious comparisons between the institutions of France and Great Britain. He was sentenced to a fine of 3,000 francs and six months' imprisonment; but both penalties were remitted by the emperor. In 1852 he was elected to the French academy. After his withdrawal from political life, Mon-
talembert busied himself chiefly with the preparation of *Les moines d'Occident depuis Saint Benoît jusqu'à Saint Bernard* (5 vols., Paris, 1860–67; 3d ed., 1868; English ed., Edinburgh, 1861). He took a lively interest in the progress of the civil war in the United States, his last pamphlet, *La victoire du Nord aux États-Unis* (Paris, 1866; English translation, Boston, 1866), being a hymn of triumph over the success of the Union arms. In 1868 he warmly espoused the cause of Poland in the volume entitled *De l'Invasion polonaise*; and in August, at the Catholic congress held in Mechlin, he read a discourse on "A free Church in a free State," which excited angry discussions between the liberal Catholics and ultramontanes. At the approach of the Vatican council he openly declared against defining the doctrine of pontifical infallibility. Besides the works already mentioned, he wrote *Du devoir des Catholiques dans la question de la liberté d'enseignement* (1844); *Saint Angéline, fragment de l'histoire de Saint Bernard* (1844); *Quelques conseils aux Catholiques* (1849); *Des intérêts catholiques aux XIXe siècle* (1852; English translation, 1858); *L'avenir politique de l'Angleterre* (1855; English translation, 1856); *Une nation en deuil, la Pologne en 1861* (1861); *Le père Laçoirdaine* (1862); and *Le Pape et la Pologne* (1864). He was one of the editors of the Correspondant. An edition of his complete works has been published by Lecoffre (9 vols., Paris, 1861–68)—see Mrs. Oliphant's "Memoirs of Count de Montalembert" (2 vols., Edinburgh and London, 1879).

**MONTALVAJ, Juan Perez de,** a Spanish dramatist, born in Madrid in 1602, died in June, 1688. His father was bookseller to the king, and the son became a licentiate in theology at the age of 17. He enjoyed the instruction of Lope de Vega, and very early wrote for the stage. At the age of 30 he had written 50 dramas and 12 autos sacramentales; and he became crazy from overwork. He left about 60 plays (Alecta, 1638; Marta, 1653). He wrote *Orfeo, a poem* (1684); "Life and Purgatory of St. Patrick" (1627); a collection of stories *Para todos* ("For Everybody," 1632); and a paraphrase on Lope de Vega (1636).

**MONTANA,** a territory of the United States, situated between lat. 44° 15' and 49° N., and lon. 104° and 116° W.; length E. and W. on the N. border, 540 m., and along the 45th parallel 460 m.; average breadth, 275 m.; area, 145,776 sq. m. It is bounded N. by British America, and E. by Dakota, and for a short distance along the 111th meridian by Wyoming. On the south, E. of the 111th meridian, it is bounded by Wyoming (along the 45th parallel); W. of the 111th meridian, it borders S. and S. W. (along the crest of the Rocky and Bitter Root mountains) and then W. on Idaho. The territory is divided into 11 counties, viz.: Beaver Head, Big Horn, Choteau, Dawson, Deer Lodge, Gallatin, Jefferson, Lew- is and Clarke, Madison, Meagher, and Missoula. The principal cities and towns are Helena (pop. in 1870, 3,106), the capital; Virginia City (367), the former capital; Deer Lodge City (788); and Argenta, Bannack, Bozeman, Diamond City, Fort Benton, Gallatin, Missoula City, and Radersburg. The population in 1870, exclusive of tribal Indians, according to the United States census, was 20,595, of whom 18,306 were whites, 183 colored, 1,949 Chinese, and 197 Indians; 12,016 were native and 7,979 foreign born, 16,771 males and 3,824 females. There were 11,529 citizens of the United States 21 years old and upward: 7,058 families, with an average of 2.29 persons to a family; 9,450 dwellings, with an average of 2.18 persons to a dwelling; 667 persons 10 years old and over unable to read; 918, including 129 Chinese and 78 Indians, unable to write, of whom 394 were natives and 524 foreigners. Of the 14,048 persons 10 years old and over returned as engaged in all occupations, 2,111 were employed in agriculture, 2,674 in professional and personal services, 1,235 in trade and transportation, and 8,030 in manufactures and mining, including 6,720 miners. The tribal Indians of Montana, according to the report of the United States commissioner of Indian affairs for 1874, number 22,486, as follows:

The Flatheads, Pend d'Orellies, and Kootenays have a reservation of 1,433,600 acres in the valley of Jocko river, a tributary of the Flathead, near Flathead lake, but most of the Flatheads have hitherto resided in the valley of the Bitter Root river and are now entitled to the reservation. The Crows have a reservation bounded W. and N. by the Yellowstone river, E. by the 107th meridian, and S. by Wyoming. The other tribes have had assigned to them the region N. of the Marias and Missouri rivers. The Blackfeet never and the Bloods seldom visit their agency, roaming most of the time N. of the British line. Besides those enumerated in the table, there are some roving Sioux not belonging to any agency. The E. portion of the territory, about three-fifths of the whole, consists chiefly of rolling table lands or plains; the W. part is mountainous. The main chain of the Rocky mountains, after forming for a considerable distance the S. W. boundary, suddenly (in lat. 45° 40') bends E. for some distance, and then runs N. about 20° W. to the N. border of the territory. The Bitter Root range, leaving the main chain at the bend, continues in a N. W. direction along the boundary to its intersection with the 116th
MERIDIAN. Enclosed by the Bitter Root mountains on the west and the main chain on the east and south is a basin occupying the N. W. portion of the territory and embracing about one fifth of its area, which is divided by mountain spurs and streams into numerous valleys and terraces. S. of this is another basin, about half its area and of similar character, occupying the S. W. extremity of the territory, and walled in by the main chain on the north, west, and south. E. of the Rocky mountains are several minor ranges. The Snow mountains enter the territory from Wyoming for a short distance, causing the Yellowstone river to make a detour in sweeping round their N. flank. N. of the Yellowstone the Belt, Judith, and Highwood mountains form an irregular group of short and broken ranges, around which the Missouri river flows N. before assuming its E. course. N. of the Missouri the plain is interrupted only by the Bear's Paw and Little Rocky mountains. The mountains are generally less rugged and elevated than further S., and some of the valleys are depressed much below the lowest point in the Great Basin. The plains vary in height from 2,010 ft. at the mouth of the Yellowstone to 4,091 ft. at the foot of the mountains. The mountain valleys vary in elevation from less than 3,000 to about 5,000 ft., while the peaks rise above the line of perpetual snow. The N. W. basin is drained by tributaries of the Columbia river; the rest of the territory by the Missouri and its tributaries. Clarke's fork of the Columbia, formed near the centre of the basin by the junction of the Flathead and Bitter Root rivers, flows N. W. into Idaho, and is navigable for some distance in Montana by small steamers. The Flathead rises in British America and has a general S. course near the foot of the Rocky mountains, near the 48th parallel into a lake of the same name (the only one in the territory), about 30 m. long and 10 or 12 m. wide. The Bitter Root rises in the S. W. corner of the basin, and has a N. course, receiving the Hell Gate river, which rises in the S. E. extremity of the basin. The latter is formed by the junction of the Deer Lodge and Little Blackfoot rivers, and a short distance before entering the Bitter Root receives the Big Blackfoot from the east. The Bitter Root above the mouth of the Hell Gate is sometimes called the Missouri. The N. W. corner of the territory is intersected by the Kootenay river. The Missouri river is formed near Gallatin in the S. W. part of Montana by the junction of the Jefferson, Madison, and Gallatin rivers, which have a general N. course, and flows N. and N. E. of Helena, to Fort Benton, whence it pursues a general E. course to the Dakota line, which it crosses near the 48th parallel. It is navigable to Fort Benton, more than 300 m. from the boundary. Its principal tributaries are Green river and Smith's or Deep river from the east; the Arrow, Judith, and Musselshell, from the south; and from the west and north, Medicine or Sun river, Teton, Marias, and Milk rivers. Jefferson river is formed by the junction of the Big Hole or Wisdom, Beaver Head, and Stinking Water rivers, which rise in the Rocky mountains in the S. W. extremity of the territory; Madison river, the middle fork, rises in the N. W. corner of Wyoming; E. of this is the Gallatin, rising between the Madison and Yellowstone rivers. The Yellowstone rises in Yellowstone lake in N. W. Wyoming, near the source of Madison river, and flows N. and N. E., draining the S. and E. sections of Montana, and joining the Missouri on the Dakota border. It is navigable in spring and early summer by large steamers 300 or 400 m. above its mouth. Its chief tributaries are the Big Rosebud river, Clarke's fork, Pryor's river, the Big Horn, Rosebud, Tongue, and Powder rivers from the south, and Porcupine river from the north. The Little Missouri river crosses the S. E. corner of the territory from Wyoming, and joins the Missouri in Dakota.—The prevailing geological formation in the east, as far as the 107th meridian on the southern boundary and the 109th on the north, is the lignite tertiary. W. of this is a cretaceous region, having its widest expanse in the north. W. and S. W. of the cretaceous are narrow belts stretching across the territory along the foot of the Rocky mountains, composed of red beds, Jurassic and carboniferous rocks, and Potsdam sandstone. The Rocky mountain range and the two basins are largely of igneous origin, consisting of basalt, granite, and various metamorphic rocks. Limestone, slate, and granite suitable for building purposes, and sands and clays adapted to brickmaking, are abundant. Bituminous coal has been found near Bannack, Helena, Virginia City, and Deer Lodge City, on the Missouri, and in several places on the Musselshell, Yellowstone, and Missouri rivers. Lignite exists in great quantities on the Missouri and Yellowstone in the E. part of the territory, and on the head waters of the Teton and Marias rivers. Hot springs and geysers are numerous about the head waters of the Missouri and Yellowstone. (See Geyser.) The precious metals, found in the metamorphic rocks, are abundant, Montana having been second only to California in the production of gold. The placer diggings are chiefly on the tributaries of the Hell Gate, Big Blackfoot, Madison, and Jefferson rivers, on the Missouri and its tributaries from the junction of the three forks to the mouth of Smith's river, and on the bars of the upper Yellowstone. The principal quartz mines are near Arpeta, Bannack, Helena, Highland in Deer Lodge co., and Virginia City. Much attention is now given to silver and copper. These metals exist in conjunction with each other and with gold, and sometimes separately. Silver is chiefly found on Flint and Silver Bow creeks, affluent of Hell Gate river; Alder and Ram's Horn gulches
of Stinking Water river; Ten Mile creek, near Helena; and on Rattlesnake creek, a tributary of Beaver Head river. Copper predominates on Beaver creek, near Jefferson City, Jefferson co.; on a branch of Silver Bow creek, near Butte City, Deer Lodge co.; and at the source of Musselshell river. Gold was first discovered, on Gold creek, a branch of the Hell Gate, in 1852, but no mining took place until the autumn of 1861. The first quartz mill was erected in the beginning of 1863. According to the returns of the United States census of 1870, which are admitted to be imperfect, the, number of gold mines was 688; hands employed, 3,534; capital invested, $2,518,618; wages paid, $1,381,699; value of materials used, $735,901; of product, $4,030,435; of, product $737,438, quartz. The bullion product of Montana, following Boss Brown's "Resources of the Pacific Slope," for the period prior to and including 1867, and the estimate of R. W. Raymond, United States commissioner of mining statistics, for the subsequent years, has been as follows:

Of the product in 1872, $385,944, and in 1873 $176,500, was silver. The deposits of gold from the territory at the United States mines and assay offices, to June 30, 1874, amounted to $36,640,618 66; of silver, to $304,361 51.

—the climate is healthy. Little rain falls, and in most parts of the territory irrigation is necessary. Much snow falls on the mountains, particularly in the N. W. basin. The average temperature in higher latitudes is the same latitude further east. In the valleys, especially in the south, little snow falls, and cattle winter without shelter, while from the dryness of the atmosphere the cold of greater altitudes is less severely felt. The average temperature at Fort Benton (lat. 47° 52' lon. 110° 40', elevation 2,674 ft.) of the year ending Sept. 30, 1873, was 41° 97'; total rainfall, 12.17 inches. The average temperature of the warmest month (July) was 69° 8'; of the coldest (December), 11° 3'. The average temperature during 1872 at Virginia City in the S. basin (lat. 45° 19', elevation 5,826 ft.) was 39° 25'; warmest month (August), 61° 3'; coldest month (December), 18° 8'; total rainfall, 9.72 inches. At Deer Lodge City in the N. W. basin, (lat. 46° 26', elevation 4,765 ft.) the average temperature for two years was found to be 42° warmest month, 69° 7'; coldest month, —15°. The total precipitation of rain and melted snow in 1870 was 16.5 inches. Fort Owen (elevation 3,284 ft.), 65 m. W. by N. of Deer Lodge City, has an average annual temperature of 47°. The variations are great, the thermometer in winter, except in the lower and more sheltered valleys, sometimes falling to 30° below zero, and rising in summer above 90°. The plains E. of the mountains are generally treeless, and (particularly in the eastern part) possess indifferent facilities for irrigation. Along the streams there is generally a growth of cottonwood, willow, alder, aspen, and similar trees, while the mountain slopes are wooded with pine, fir, spruce, cedar, and hemlock. Timber is in part imported from the N. W. basin.
assessed in 1873 was 19,905; cattle, 104,777; mules, 1,606; sheep, 10,597. The whole number of manufacturing establishments in 1870, according to the census, was 201, having 33 steam engines of 822 horse power, and 46 water wheels of 795 horse power; hands employed, 701; capital invested, $1,794,900; wages paid, $970,843; value of materials used, $1,316,331; of products, $2,494,511. The principal townships have telegraphic communication with the east and the Pacific coast. There are five national banks, with an aggregate capital of $350,000.—The government is similar to that of the other territories. The executive officers are a governor and secretary, appointed by the president with the consent of the senate for four years, and a treasurer, auditor, and superintendent of public instruction, created by local law. The legislative power is vested in a council of 18 and an assembly of 26 members, elected by the people for two years. Judicial authority is exercised by a supreme court, district courts, probate courts, and justices of the peace. The supreme court consists of three justices, appointed by the president with the consent of the senate for four years, and has appellate jurisdiction. A district court with general original jurisdiction is held by a justice of the supreme court in each of the three judicial districts. There is a probate court for each county, with the usual powers of such courts. Justices of the peace have cognizance of inferior cases. According to the United States census of 1870, the assessed value of real estate was $2,728,128; of personal property, $7,215,283; true value of both, $15,184,522. The total taxation not national was $198,597, of which $38,131 was territorial, $107,396 county, and $3,000 town, city, &c.; county debt, $276,219; town, city, &c., $2,500. The valuation for purposes of taxation in 1873 was $9,805,745; taxation for territorial purposes, $39,214 98. The receipts into the territorial treasury for the year ending Dec. 1, 1873, including $454 64 on hand at the beginning of the period, were $66,517 73; disbursements, $56,792 15; balance, $9,725 58. The net territorial debt at the 1st of January, 1879, amounted to $128,762 47, a decrease during the year of $13,786 52; $92,288 44 of this amount was in bonds bearing 12 per cent. interest. The aggregate debt of the several counties on March 1, 1873 (Lewis and Clarke to Sept. 1), was reported as $432,987 74. The territorial penitentiary is at Deer Lodge City. According to the report of the superintendent of public instruction for 1873, the number of children of school age (4 to 21 years) was 3,517; number attending public schools, 1,881; average attendance, 940; number of organized school districts, 91; of schools taught during the year, 90; teachers employed, 99 (50 males and 49 females); average pay per month, $68 41; average length of schools, 824 days; number of school houses, 51; amount raised for schools by county tax, $31,350 49; by district tax (in Madison co.), $934 55; amount apportioned during the year from all sources, $83,161 50; private schools taught during the year, 11, attended by 149 pupils. There are graded schools in Deer Lodge City, Helena, and Virginia City. The number of schools of all classes reported by the census of 1870 was 54 (46 ungraded common, 1 classical, 6 day, 7 day and boarding, and 1 parochial and charity), having 54 male and 81 female teachers, 1,027 male and 718 female pupils, and an income from all sources of $41,170. There were 141 libraries, containing 19,700 volumes, of which 128 with 14,690 volumes were private; and 10 newspapers (3 daily, 1 tri-weekly, and 6 weekly), issuing 2,860,600 copies annually, and having a circulation of 19,680. The number of church organizations was 15 (1 Christian, 2 Episcopal, 7 Methodist, and 5 Roman Catholic), having 11 edifices, with 3,850 sittings, and property valued at $90,300.—Montana was set off from Idaho and given a territorial government by the act of May 26, 1864. Its settlement dates from the opening of the gold mines. By the act of Feb. 17, 1873, a tract of about 2,000 sq. m., between lat. 44° 30' on the north, Wyoming on the east, and the Rocky mountains on the south and west, previously belonging to Dakota, was annexed to Montana. Helena became the capital in 1875.
MONTANISTS

was acting in Paris, the tragedy Commata and a translation of Legouvé’s Médee.

MONTANISTS, a sect of the 2d century, so called after Montanus of Phrygia. He is said to have been a priest of Cybele, and to have announced himself about 160 as a prophet, who was to carry Christianity forward to perfection. He taught a permanent extraordinary influence of the Paraclete, manifesting itself by prophetic ecstasies and visions, assigned to doctrines and rites a subordinate significance, and demanded the most rigid asceticism as a manifestation of internal purity. Besides the ordinary fasts, he prescribed annual and weekly ones, and declared second marriages and flight from persecution to be sins. He represented the beginning of the millennium as very near at hand, and Pepuzu in Phrygia as the place which would be its centre. His followers, who were also called Cataphryges and Pepuziani, found a zealous and gifted advocate in Tertullian, and included many prophets, among whom Maxenilla and Priscilla are especially celebrated. The members of the ruling church were designated by them as psychi, while they assumed themselves the name pneumatii. They were opposed especially by the Alexandrian school, and condemned by several provincial councils. They were numerous in Mysia, Lydia, and Phrygia, where some towns, as Pepuzu and Thyatira, were exclusively inhabited by them. Thence they spread into other parts of Asia Minor, especially into Cappadocia, Galatia, and Cilicia. In Constantinople and Carthage also they were very numerous. The literature of the modern Tubingen school represents Montanism as a reaction of Jewish Christianity against Paulinism. — See Wernsdorf, De Montanisti (Dantzie, 1751; strongly favorable); Münster, Effitata et Oracula Montanistarum (Copenhagen, 1829); Kirchner, De Montanistiis (Jena, 1833); Schwegrer, Der Montanismus und die christliche Kirche des zweiten Jahrhunderts (Tübingen, 1841); and Baur, Das Christentum und die christliche Kirche der drei ersten Jahrhunderte (2d ed., 1860).

MONTANUS. See MONTANISTS.

MONTANUS, Ardas. See Ardas Montanus.

MONTARGIS, a town of France, in the department of Loiret, on the left bank of the Loing, and at the junction of the canals of Briare, Orleans, and the Loing, connecting the navigation of the Seine and the Loire, 62 m. S. by E. of Paris, and 40 m. E. by N. of Orleans; pop. in 1866, 7,757. — The town is well built on a plain which extends from the river to the neighboring forest of Montargis; and it has an active trade, chiefly in grain, wax, honey, and agricultural products. It has also considerable manufactories of cotton goods, cutlery, paper, &c. The most interesting building is the ruin of the once extensive castle of Montargis, on a hill near the town. This was built by Charles V. (1364—80), and was very strongly fortified, with accommodations for an unusually large garrison. The great hall of the castle (55 by 184 ft.) was elaborately decorated. Among its ornaments was a carving of the combat of a dog and an accused murderer, which tradition represents as having taken place at Paris in 1371, in accordance with the custom of the ordeal of battle then in vogue. The dog having overcome in the combat the alleged murderer of his master, the criminal confessed his crime and was executed. From the carving, this story became universally known as that of the “dog of Montargis.”

MONTAUBAN (Lat. Mons Albanus), a town of Guienne, France, capital of the department of Tarn-et-Garonne, on the river Tarn, 343 m. S. S. W. of Paris; pop. in 1872, 25,624. It stands on a high plateau, and has wide clean streets and a thrifty appearance. It contains a fine cathedral of the 18th century, and there is a stone bridge over the Garonne which dates from the 14th. There is a lyceum, a normal school, a Protestant faculty of theology, a public library, and a gallery of paintings which includes many by Ingres, a native of the place. The manufactures are extensive, embracing silks, woollens, porcelain, starch, candles, pens, and pharmaceutical products; and there is a large trade in leather, grain, and wine, the surrounding country being very productive. Montauban was founded by Alphonse, count of Toulouse, in 1144, and was made the seat of a bishop in 1317. It became a Protestant stronghold in the 16th century, and its inhabitants were subjected to severe persecution. In 1621 it was besieged by the royal army under De Laynes, which at the end of three months, after numerous assaults, was obliged to withdraw. In 1629 it submitted to the royal authority, and its defences were razed. Subsequently it suffered from the dragonnades.

MONTBELLARD, or Mombellard (Ger. Mompelgard), a town of Franche-Comté, France, in the department of Doubs, at the confluence of the Allan and the Lusine, on the Rhône and Rhine canal, 48 m. N. E. of Besançon; pop. in 1866, 6,475, most of whom are Lutherans. It has a chamber of industry and agriculture, a Protestant normal school, a communal college, a library of 9,000 volumes, and other educational and benevolent institutions. The principal manufactures are woollen and linen fabrics and muslins. It was formerly the capital of a county in Burgundy, which after the extinction of the male line of counts in 1395 passed by marriage to the house of Württemberg, though at the same time it was under the suzerainty of France; and it was wholly ceded to France in 1801.

MONT BLANC (Fr., “White mountain,” so called from the snow which covers it), the highest of the Alps, and with the exception of Mt. Elburz in the Caucasus the highest mountain in Europe, on the confines of Savoy, France, and Piedmont, Italy, in lat. 45° 50' N., lon. 6° 52' E. It extends about 13 m. from N. E. to S. W., with a breadth of 5 to 6 m. Its highest elevation, a narrow pinnacle, is 15,792
and its outlying flanks consist of calcareous strata turned up against the great central mass. The sides, to the height of 3,000 to 4,000 ft. above Chamouni, are skirted with forests. The surface of its higher parts is diversified and very irregular; there are numerous jutting rocks, called *aiguilles* or needles; large fields of ice, often broken into fissures of unknown depth; and grottoes excavated beneath the masses of ice by the warmer temperature below, and hanging with splendid stalactitic formations. Glaciers frequently sweep down its sides. At night the summit shines with a faint light, which is thus accounted for: there is high in the atmosphere a zone of thin vapor which is still lighted by the sun after Mont Blanc has ceased to be within range of its rays, and this vapor reflects a part of the light which it receives upon the summit of the mountain. The first ascent of Mont Blanc was made with great danger and difficulty by Dr. Paquet and Jacques Balmat in August, 1786; but during the preceding ten years several unsuccessful attempts had been made. They found the cold so excessive that they remained on the summit only half an hour. The next year De Saussure accomplished the ascent, and made a variety of scientific observations. Albert Smith's ascent in 1851 and subsequent pictorial and dramatic descriptive entertainment, and his "Story of Mont Blanc" (London, 1854), gave unusual popularity to the subject in England for several years. A record of two ascents (1858-'9) by Prof. Tyndall is in "The Glaciers of the Alps" (London, 1869). In 1855 Prof. J. D. Forbes published a "Tour of Mont Blanc and Monte Rosa," and subsequently a series of papers on the theory, measurement, and movement of the glaciers. There are also numerous recent accounts of ascensions by members of the English Alpine club. The achievement is no longer considered either dangerous or difficult. The guides and all matters relating to them are regulated by the French government, and ascents are frequent.

**MONTBRISON**, a town of France, in the department of Loire, on the Vizey, an affluent of the Loire, 37 m. S. W. of Lyons; pop. in 1866, 6,475. The most notable building is the principal church, Notre Dame de l'Espérance, built from 1223 to 1466. Its industry and trade are of no great importance. It was formerly the capital of the department.

**MONTCALM**, a S. central county of the S. peninsula of Michigan, watered by tributaries of the Muskegon, Chippewa, and Grand rivers; area, 720 sq. m.; pop. in 1870, 13,629. It has an undulating surface and a fertile soil. The Detroit, Lansing, and Lake Michigan railroad and the Stanton branch traverse it. The chief productions in 1870 were 136,778 bushels of wheat, 117,163 of Indian corn, 63,925 of oats, 178,010 of potatoes, 49,541 lbs. of wool, 50,755 of maple sugar, 43,346 of butter, and 13,141 tons of hay. There were 1,827 horses, 2,256 milch cows, 2,096 other cattle, 13,465 sheep, and 3,346 swine; 3 manufactories of boots and shoes, 4 of carriages and wagons, 3 of saddlery and harness, 4 of sash, doors, and blinds, 2 flour mills, and 49 saw mills. Capital, Stanton.
MONTCALM, a S.W. county of Quebec, Canada, N. of the St. Lawrence river; area, 4,027 sq. m.; pop. in 1871, 12,742, of whom 10,794 were of French and 1,557 of Irish origin and descent. It is watered by the Gatineau, Du Liévre, Rouge, North, and Lac Ouaure rivers, and other streams. Capital, Ste. Julienne.

MONTCALM DE CANDIAC. See CANDIAC.

MONTCALM DE SAINT-VÉRAN, Louis Joseph, marquis de, a French soldier, born at the château of Candiac, near Nimes, Feb. 28, 1712, died in Quebec, Sept. 14, 1759. He entered the army when 14 years old, served in Italy in 1734, distinguished himself in Germany under Belleisle during the war for the Austrian succession, and fought in Italy again, where he gained the rank of colonel in the disastrous battle of Piencenza (1746). In 1756 he was appointed to command the French troops in Canada, where he arrived about the middle of May. He captured Fort Ontario at Oswego on Aug. 14 and the next year forced Fort William Henry, at the head of Lake George, with a garrison of 2,500 men, to surrender, in discretion, and thus became possessed of 42 guns and large stores of ammunition and provisions. Montcalm had suffered from scarcity of provisions, and was opposed to an enemy far superior in numbers and discipline to his own troops, which consisted mostly of Canadian volunteers; yet he held his ground firmly, when, in the campaign of 1758, the English under Abercrombie marched from the south toward the French dominions. Montcalm occupied the strong position of Fort Carillon (Ticonderoga), made it still stronger by intrenchments, and at the head of about 3,600 men awaited the attack of 15,000. After a fierce battle which lasted four hours (July 8, 1758), the British retreated in disorder. The personal bravery of Montcalm increased his popularity among his soldiers; and if he had received timely reinforcements, he could have maintained the supremacy of the French in North America. But the want of energy on the part of the home government, the scarcity of food all over New France, and personal dissensions between the governor and the military commander, forbade him to look for much assistance; and in the midst of victory he expressed his conviction that in a few months the English would be masters of the French colonies in America. Resolved, as he said, "to find his grave under the ruins of the colony," he actively prepared for the campaign of 1759. The English spared no exertions to make their conquest sure; troops were sent from Europe; the colonial regiments were thoroughly reorganized; and a strong fleet cooperated with the land forces. While Amblerst and Prideaux were maneuvering to dislodge the French from the vicinity of Lake George and Lake Ontario, Gen. Wolfe, at the head of 8,000 chosen troops, supported by the fleet in the St. Lawrence, appeared before Quebec. The conquest of Canada depended upon the taking of that city; and to protect it Montcalm had concentrated his principal forces on the banks of the Montmorency. Being attacked in front by Wolfe, July 31, he repelled him with considerable loss. Wolfe then changed his plans; he secretly landed his troops by night on the left bank of the St. Lawrence, above Quebec, climbed the table land that overhangs the city, and on the morning of Sept. 13 appeared with his whole force on the heights of Abraham, in the rear of the French army. By 10 o'clock the two armies, about equal in numbers, each having fewer than 6,000 men, were drawn up before each other. Montcalm led the attack in person, but his troops soon broke before the deadly fire of the British; and when Wolfe, at the head of the 28th and the Louisburg grenadiers, gave the order to charge with bayonets, they fled in every direction. Wolfe fell in the moment of triumph; Montcalm had received a musket ball earlier in the action, and was mortally wounded while attempting to rally a body of fugitive Canadians a few moments after Wolfe was borne from the field. On being told that his death was near: "So much the better," he said; "I shall not live to see the surrender of Quebec." He died the next morning, and the French lost all Canada.

MONT DE MARSE, a town of Gascony, France, capital of the department of Landes, 63 m. S. of Bordeaux, at the junction of the Douze and Midou, which here form the navigable Midiou; pop. in 1866, 8,456. It has a communal college, warm mineral springs, and manufactories of coarse woollen cloths, blankets, and sail cloth.

MONT DE PIÉTÉ, a public institution in continental Europe, the original object of which was to deliver the needy from the charges of Jewish and Lombard money lenders. One is said to have been founded at Freising in Bavaria about the year 1200 by a charitable association and with the sanction of Pope Innocent III.; but it is more generally believed that the first mont de piété was established in Ferrugia in the latter half of the 15th century, and derived its name (monte di piété) from the hill upon which it was situated. The earliest one in France was probably that of Rheims. Marseilles, Montpellier, and other French cities possessed mons de piété in the 17th century; as in Italy, they were supported by charitable endowments, but they charged interest at the rate of 15 per cent. upon all loans exceeding five francs, whereas the Italian institutions only charged a small rate, rarely exceeding 5 per cent., to cover the indispensable expenses. The mont de piété of Paris was opened Jan. 1, 1778, and was authorized in 1779 to make a loan guaranteed by the income of the hôpital général. During the revolution it was closed; and the usurious rates of interest charged by the money lenders during the reign of terror caused its reopening in 1803 to be hailed with delight by the poor. In 1881 it was placed under the charge of an administrative council; and in 1851 the mons de piété were placed

MONT DE PIÉTÉ
under the superintendence of a select committee. The Paris mon de piété is situated in the rue des Blancs Manteaux, with two large branches in the rue Bonaparte and the rue de la Roquette. There are also about 20 agents scattered over Paris, appointed by the administration. The mon de piété makes advances from three francs upward at a rate fixed in 1854 at 4½ per cent. per annum, which has since been as high as 9 per cent. In 1873 the rate was 8 per cent. No money is advanced except upon securities, the value of which is assessed by a committee of appraisers, four fifths of the value being advanced upon articles of gold and silver, and two thirds upon all other articles. A receipt for the article pledged is given to the owner, who must prove his identity in order to reclaim it. The articles pledged, if not redeemed, are sold at public sales at the expiration of 14 months, and the surplus money, if any, is paid to the owner of the article if applied for within three years. The annual receipts and expenditures of the mon de piété are respectively about 50,000,000 francs, with a balance of about 230,000 francs in favor of the institution. The most profitable customers of the mon de piété are not the poor, but the needy of the higher classes. During the rule of the commune in Paris in 1871, the official organ published a decree, May 12, that all articles of wearing apparel, linen, books, bedding, and working tools, pledged at the mon de piété for a sum not exceeding 20 francs, could be taken out without any payment, the receiver of money on such articles proving his identity; and it was estimated that the sum to repay such advances would be about 8,000,000 francs. The largest number of applications for redemption is on Saturdays, New Year's and Easter. In 1873 there were 46 mons de piété in France, with a capital of about 50,000,000 francs, making yearly loans of about 60,000,000. In five of the establishments the loans are gratuitous; in the rest the rate of interest varies. There are numerous similar establishments in Holland, Belgium, and Germany. In the latter country the rate of interest varies from 8 to 12 per cent.; loans rarely exceed the amount of $150, and the smallest pledge must be worth at least $2, one month being the shortest and a year the longest term of the loan. The rate of interest in the Russian mons de piété is 6 per cent. China is said to possess very ancient institutions of the kind, under the direction of great public dignitaries, which seem to be conducted upon more charitable principles than those of Europe, the rate of interest there being only from 2 to 3 per cent.—These institutions are represented in Great Britain and America by pawn shops, which differ from them in being private establishments regulated by special laws.

MONTEBELLO, a small village of Italy, on the road from Alessandria and Voghera to Piacenza; about 4 m. E. of Voghera. It was the scene of a victory of the French under Lannes over the imperialists, June 9, 1800, five days before the battle of Marengo, and of an engagement between the French and Sardinian allies and the Austrians, May 20, 1809, in which, with a loss of about 650, the allies defeated the Austrians, who lost about 1,000 killed and wounded and 200 prisoners.

MONTE CASINO. See Casino.

MONTECASULLI, or Monteaccoli, Raimondo, count, an Austrian general, born near Modena in 1608, died in Linz, Oct. 14, 1681. He entered the Austrian army in 1627, and distinguished himself in the thirty years' war. On Sept. 7, 1631, he was wounded and taken prisoner in the battle of Breitenfeld, and liberated in 1632. For his gallantry in the assault on Kaiserslautern, in July, 1635, he was promoted to a colonelcy. In 1639, while attempting to prevent the Swedes from crossing the Elbe at Melnik, in Bohemia, he was worsted and taken prisoner. On his release two years afterward he joined the imperial army in Silesia, defeated the enemy at Troppau, and took the town of Bries. On the outbreak of war in Italy he was sent with 50,000 men from the duke of Modena the title of brigadier general and the command of his cavalry; but he soon returned to Austria, was appointed in 1644 lieutenant field marshal and a member of the aulic council of war, supported in 1645 the archduke Leopold in his expedition against Rakoczy of Transylvania, and was sent to oppose Turenne on the Rhine. The next year, in conjunction with Johann von Werth, he completely routed the Swedes in Silesia, and received the rank of general of cavalry. Being in 1657 placed in command of the army sent by the emperor to protect John Casimir of Poland against the Transylvanians, he crossed the Swedes, which, about the treaty of Oliva (1660), he commanded the army sent against the Turks, whom he drove from Transylvania, and on Aug. 1, 1664, gained on the banks of the Rang the victory of St. Gotthard, which for the time delivered Christian Europe from Turkish invasion. When in 1672 Louis XIV. threatened Holland, Monteaccoli commanded the imperial army which took the field in behalf of the Dutch, and baffled the plans of Turenne, whom he worsted on several occasions. For a while superseded in the command by the elector of Brandenburg, he was soon recalled (1675), as the only general who could hold his ground in presence of the great French marshal. On the death of Turenne he drove the French army across the Rhine, and invaded Alsace; but his progress was stopped by the prince of Condé, who obliged him to raise the siege of Hagena and recross the Rhine. After this campaign Monteaccoli returned to Vienna and devoted his time to scien-
ence, art, and literature. The dignity of a prince of the German empire was conferred on him by the emperor Leopold in 1879, and soon afterward the king of Naples gave him the duchy of Meli. He lost his life by the fall of a beam. He left a personal memoir (translated into Latin under the title of Commentarius Belllici, fol., Vienna, 1719), containing disquisitions on the military art and an account of his campaigns against the Turks. His writings were published in the original Italian by Ugo Foscolo (2 vols. fol., Milan, 1807-8), and by J. Grassi (2 vols. 4to and 8vo, Turin, 1821).

Montere, Sir Moses, a Jewish philanthropist, born in London, Oct. 24, 1784. His ancestors had been wealthy bankers in London for several generations. He married, June 10, 1812, Miss Judith Cohen, a sister-in-law of Nathan Meyer Rothschild, the founder of the London branch of that house. While visiting Palestine in 1829 with his wife, he became interested in his coreligionists there. In 1837 he bought the sheriff of London and was knighted on the queen's visit to the city, and in 1846 he was made a baronet. He made a second journey with his wife to the East in 1846, in company with Cremieux, on occasion of the persecution of the Jews in Damascus, and visited Palestine on several other occasions, always in the interest and for the relief of the Jews. In 1846 he prevailed upon the emperor Nicholas to suspend a ukase against the Jews, and was invited to visit Poland to suggest measures for the amelioration of the condition of its Jewish inhabitants. In 1854 he collected funds for the relief of the sufferers by the famine in the East, obtained from the sultan the privilege of holding real estate, and established poorhouses in Jerusalem, and also promoted industry and agriculture. In 1863, having secured at Madrid the co-operation of Queen Isabella, he obtained a firman from the sultan of Morocco in favor of the persecuted Jews, guaranteeing their equal protection with Christians. In 1866, in his 82d year, he made his last visit to his protégés in Palestine, who had been afflicted by the cholera, and whose crops had been destroyed by locusts. In the following year he went to Bucharest to use his influence against the ill treatment of the Jews in Roumania. In 1867 he endowed a Jewish college at Ramsgate in honor of his wife, who had died childless, Sept. 24, 1862. The freedom of the city of London was tendered to him in 1873, with a valuable present, in token of his benevolence. Lady Montefiore published "Notes of a Private Journal of a Visit to Egypt and Palestine" (London, 1844).

Montefiore, Émile, a French author, born in Limoges, June 24, 1826. He studied in Paris, and became known as a contributor to the Revue des Deux Mondes, with which he was connected for many years. He was the first to familiarize the French with the writings of Emerson, some of whose essays he translated (1850). He also translated Macaulay's "History of England" (2 vols., 1853 et seq.), and Shakespeare's complete works (1865-70). Among his most recent writings are: Les Pais Bas, souvenir de Flandre et de Hollande (1869), and Impressions de voyage et d'art, souvenir en Bourgogne (1873).

Montélimart, a town of France, in the department of Drôme, 83 m. S. of Lyons; pop. in 1866, 11,100. It has a citadel, six churches, a communal college, manufactories of figured silk, and an extensive trade in wine and fruits. Here the doctrines of Calvin found the first adherents in France. In 1569 the place was unsuccessfully besieged by Coligny.

Montemolin, Count of. See Carlo, III.

Montemorelos. See Morelos.

Monten, Dietrich, a German artist, born in Düsseldorf in 1779, died in Munich, Dec. 18, 1848. He studied at the academy of his native city, and under Peter Hess at Munich, became eminent as a painter of battles, and was employed by Cornelius in preparing the battle scenes of one of his most celebrated frescoes. Among his most esteemed works are: "The Departure of the Poles from their Fatherland in 1831," "The Death of Max Piccolomini," "The Death of Gustavus Adolphus," and "The Death of Duke Frederick William of Brunswick in the Battle of Quatre-Bras."

Montenegro (Slav. Tsernagora or Tchernagora, Turk. Karadagh, Alb. Mëj Zëzë or Mël Beyë, Black Mountains), a semi-independent principality in European Turkey, near the Adriatic, bordering on the Turkish provinces of Herzegovina, Bosnia, Albania, and the Dalmatian circle of Cattaro; area, 1,700 sq. m.; pop. about 120,000, chiefly Slavic. Capital, Cetinje. The limestone ridges of the Dinaric Alps traverse the territory, and it has hardly any plains. The principal mountains are from 5,000 to 8,000 ft. high. Most of the streams, among them the Moratcha, flow into the lake of Scutari on the S. E. border. The mulberry, olive, almond, fig, peach, pomegranate, and other fruit trees, and the vine, are cultivated. The chief productions are maize, potatoes, and tobacco. Agriculture is backward, but every piece of land capable of tillage is planted. Fishing is largely carried on. The winters are very cold, but the climate is healthful. The number of villages is between 200 and 300, mostly in hollows and on the slopes of mountains. The men till the land, and the inferior drudgery is performed by the women. The men wear a white or yellow cloth frock, reaching nearly to the knees, secured by a sash, and a red Féz cap and white or red turban. The women wear a frock or pelisse of white cloth, much longer than that of the men, and both sexes wear sandals of untanned ox hide, and carry the struka (somewhat like the Scotch plaid) over their shoulders. The imports are cattle and some horses, tobacco, salt, copper, iron, oil, wax candles, wine, brandy, coffee, sugar, arms, glass, sandals, and Féz caps. The exports are smoked mutton, sumach wood.
and leaves, salted and dried fish, wax, honey, vegetables, fruits, and some silk. The principal market is Cattaro. The produce is carried thither chiefly by women, and it is only in the eastern regions of the country that they are assisted in their labor by the use of mules and asses. There is no port and no outlet to the sea. The Montenegrins are divided on the Austrian government for permission to pass goods to and from the sea. Manufactures are limited to articles of domestic necessity. Taxes levied on each household, together with duties on salt, fish, and dry meat, the monopoly of tobacco, and the land rent of several convenuts, amounted in 1872 to about $28,000, to which Russia annually adds about $20,000 to cover the tribute due to the Porte. The Montenegrins are all of the non-united Greek church; excepting a few Roman Catholics who belong to the Turkish diocese of Scutari, and every village has its church. The head of the church is the vladika, or prince-bishop, who till 1852 was also the secular ruler; he is elected from among the monks or unmarried clergy by the national assembly, and may be deposed by it; he has an annual revenue of $16,000. The number of priests is about 200; they join in war and the other occupations of the people. Priests must be married before they can be consecrated. The convenuts are those of Cettigne, Ostrog, and St. Stefano. Education is neglected, and many of the priests are unable to read and write; but several schools were established in 1841, and a printing press in Cettigne, which has issued several books. The first political newspaper was established in 1871. Since the separation of the secular from the ecclesiastical power on the accession of Danilo I. in 1852, the government has been a limited monarchy, hereditary in the male line of the family of Petrovitch of Niegosh. The prince is assisted by a senate of 16 members, which also acts as a supreme court. The legislative functions are exercised by the skupshchina, or national assembly. There is no standing army except the body guard of the prince and a corps of gendarmes, together numbering 1,000 men. The language of Montenegro is a pure dialect of the Ilyrico-Servian branch of the Slavic, not corrupted by admixture with foreign words. In ancient times Montenegro formed part of Illyricum. The present principality afterward constituted the S. W. corner of the old kingdom of Servia, which in the 14th century extended from the Adriatic to the Black sea. Toward the end of that century Servia became tributary to the Porte. Montenegro, or Zeta as it was then called, secured its independence under the rule of George Balsha, the son-in-law of the last Servian king, and his descendants. The last of the line (eventually known by the name of Tehernoyevitch) married a Venetian lady, and in 1516 abdicated and went to Venice, leaving the government in the hands of the bishop, whose successors (since about 1700 all of the house of Petrovitch) ruled the country as prince-bishops till one of them proclaimed himself secular prince as Danilo I. (1852). Turkey regarded Montenegro as a portion of her empire, and in 1823 the pasha of Scutari invaded the country with a powerful army, but was repulsed with severe losses. At the beginning of the 19th century the Montenegrins sought the protection of Russia against Turkey. The Turks sent several expeditions thither, one of which in 1714, consisting of 120,000 men, defeated the Montenegrins, and carried more than 20,000 of them into captivity. A war with Venice compelled the Turks to withdraw their forces, and successive invasions were repelled, in one of which, in 1796, 30,000 Turks were slain. In 1820 another invasion by the Turks was repulsed with heavy loss, as was still another in 1832. After a border warfare had continued for many years, at the close of 1852 Omer Pasha with a formidable force was sent to subdue the mountainers. The position of Montenegro was most critical, when peace was restored by the intervention of Austria and the mediation of the Porte. There was much energy in improving the laws and the condition of the country. Fresh collisions with Turkey took place in 1858; and one of Danilo's uncles was detected in treasonable proceedings. On Aug. 12, 1860, Danilo was assassinated, and was succeeded on the throne by his nephew Nikolo Petrovitch-Niegosh. The insurrection which broke out in Herzegovina in 1861, being favored by the Montenegrins, was followed in 1862 by the invasion of Montenegro by Omer Pasha with an army of 80,000. In August the Turks appeared before Cettigne, and Nikolo soon submitted by treaty to the sovereignty of the Porte. No complications arose with Turkey in 1874 on account of murders committed on the Albanian border, and Montenegro declared war in January, 1875, but a compromise was effected toward the end of that month.

MONTÉPIN, Xavier Aymon de, a French author, born at Apremont, Haute-Saône, March 18, 1824. He began life as a journalist, and wrote in conjunction with the marquis de Foudras the novels Les chevaliers du languenet (10 vols., 1847) and Les vierres d'autrefois (4 vols., 1848), to which he added many others equally descriptive of the elegant, demi-monde, and Bohemian life of Paris. He gained great notoriety by the suppression of his licentious Filles de plâtre (7 vols., 1855), but continued to produce other voluminous works of a similar character. Among the most recent are Le bigame, Le mari de Marguerite, Confessions de Tulla, Les drames de l'adultere, La comtesse de Nancey (all in 1873), and La royante (1873-4). He also assisted the elder Dumas as a playwright.

MONTEREY, a W. county of California, bordering on the Pacific, bounded E. by the Coast range of mountains, intersected by the Salinas or Buenaventura river, and drained also by the San Benito, and another mountain stream, area, 4,536 sq. m.; pop. in 1870, 9,876, of whom 280 were
MONTEREY

Chinese. The surface is traversed by several ranges. The best land lies in the valleys of the Salinas and San Benito, and the varieties of elevation permit the production of a great diversity of fruits, of which those that reach the greatest perfection are the fig, peach, apricot, grape, apple, pear, and olive. The county is thinly wooded except on the coast. Silver, copper, lead, quicksilver, and granite are among the mineral resources. Stock raising is the principal occupation. The Southern Pacific railroad traverses the county. The chief productions in 1870 were 744,995 bushels of wheat, 21,411 of oats, 681,115 of barley, 131,213 of peas and beans, 69,850 of potatoes, 59,120 lbs. of tobacco, 1,064,510 of wool, 423,385 of butter, 713,500 of cheese, and 18,927 tons of hay. There were 9,017 horses, 9,370 milch cows, 32,266 other cattle, 298,877 sheep, and 13,952 swine; and a number of manufactories. San Benito co. was formed from the E. part in 1874, reducing the area given above. Capital, Monterey, on a bay of the same name, 55 m. S.E. of San Francisco; pop. in 1870, 1,112. It was formerly the seat of an important Roman Catholic mission, and was the capital of California till 1847.

MONTEREY, a city of Mexico, capital of the state of Nuevo Leon, on a river of its own name, 450 m. N. W. of Mexico; pop. in 1869, 13,534. It is on a rapidly sloping plain about 6 m. from the Sierra Madre, 1,500 ft. above the sea. The streets are regular, well kept, and well lighted; and the houses, chiefly of limestone, are well built and tasteful. The principal square is embellished with a marble fountain by native artisans. Among the more noteworthy edifices are the cathedral, two churches, one of which is among the handsomest in the republic, and the municipal and government palaces. Monterey has also a fine hospital, a prison, barracks, and abattoir, a seminary, two colleges, and 15 public and 20 private schools. The climate is comparatively mild, but subject to sudden changes. Monterey is one of the most prosperous manufacturing towns in Mexico. There are cotton, paper, flour, and saw mills, and manufactories of nails, bricks, carriages, morocco, candles, soap, sugar, beer, and brandy. Modern machines and implements are being rapidly introduced from the United States, whence are also imported large quantities of books and other merchandise.—The city was founded in 1596, on the site of the former Ciudad de Leon, and received the name of Nuestra Señora de Monterey. In 1777 it was made a bishopric. It has frequently been visited by cholera and other epidemics. In the early part of the war between the United States and Mexico, Monterey was a strong military position amply fortified, and held by the Mexican Gen. Ampudia with 10,000 regular troops. On Sept. 19, 1846, Gen. Taylor with 6,600 men attacked it. The city was bombarded in the morning, from batteries erected during the night; then a brigade under Gen. Quitman carried the lower part of the town by assault, while Gen. W. O. Butler with the first Ohio regiment entered at another point. Gen. Worth carried the heights south of the river and the Saltillo road, and turned the guns upon the bishop's palace; next morning he stormed the height overlooking the palace, and turned its guns upon the flying Mexicans. The main body of the Mexicans retired step by step, taking advantage of the solidly built houses, and the Americans fought their way through the city, reaching the principal plaza on the 23d. Ampudia capitulated on the 24th. The American loss was 120 killed and 368 wounded; the Mexican loss was not ascertained.

MONTEPAN, Françoise Athénaës de Rochechouart de Mortemart, marquise de, a mistress of Louis XIV. of France, born at the château of Ton-nay-Charente in 1641, died at Bourbon-l'Archambault in 1707. She was the younger daughter of Rochechouart, first duke of Mortemart, and was educated in the convent of St. Marie at Saintes. She was first known as Mlle. Tonnay-Charente, and was maid of honor to the duchess of Orleans. At the age of 22 she married Pardaillan de Gondrin, marquis de Montespan, and became lady in attendance to the queen. Her beauty, wit, and conversational powers at once made a sensation; but for several years the king seemed scarcely to notice her. She secretly became his mistress however about 1668, and was openly declared such two years later. Her husband, who attempted to break off the connection, was banished to his estate, and was legally separated from her in 1676. For 14 years her influence over the king was unbounded; she prevailed upon him to legitimate their children, who were confided to the care of the widow Scarron, afterward Mme. de Maintenon, who in time supplanted Mme. de Fontanges, the immediate successor of their mother in the royal affections. She was finally separated from him in 1686, and in 1691 she was obliged to leave Versailles. She retired to a convent, and tried in vain to be reconciled with her husband. She now devoted herself to benevolence and mortification, distributing most of her income to the poor. Her children by the king were: the duke of Maine, the count of Vexin, Mesdeoiselles de Nantes, de Blois, and de Tours, and the count de Toulouse, besides three others who died in childhood. The marquis d'Antin was her son by her husband.

MONTESQUIEU, Charles de Secondat, baron de, a French philosopher, born at the château of La Brede, near Bordeaux, Jan. 18, 1636, died in Paris, Feb. 10, 1755. He was remarkable during his youth for diligent studies not only of jurisprudence but of literature and philosophy. At the age of 20 he composed a work designed to prove that the paganism of the ancient philosophers and authors did not merit eternal damnation. At the age of 25 he was admitted to the parliament of Bordeaux, of which he became président à mortier two years
later, succeeding his uncle in that office. He applied himself scrupulously to its duties, though chiefly devoted to the pursuits of literature. A literary and musical society formed at Bordeaux in 1716 was through his influence transformed into an academy of sciences, to which he contributed memoirs chiefly on natural history until almost entire blindness forbade this study. Among his early writings were dissertations on the physical history of the earth (1719) and on the policy of the Romans in their religion. His first work that attracted general attention was the Lettres persanes (1721). It consists of letters purporting to have been written by a Persian travelling in France, assailment beneath a transparent veil the whole system of principles prevalent in church and state. It abounds in paradoxes, jests, and sprightly satire, and also in profound views of law, commerce, and social problems. In 1726 he retired from the duties of the magistracy to devote himself solely to literature; was received into the French academy in 1728, having overcome the opposition of Cardinal Fleury by modifying obnoxious passages in his Lettres persanes; and soon after began to travel through Europe to collect materials for an elaborate work on politics and jurisprudence, spending about two years in England, where he became a member of the royal society. He returned to La Brède after an absence of four years, and after two years of retirement published his Considerations sur les causes de la grandeur et de la decadence des Romains (Paris, 1734). His great work, De l'esprit des lois (2 vols., 1748), was the result of 20 years of labor; 22 editions were issued in 18 months, and it was translated into most of the European tongues. It ultimately became the oracle of the friends of moderate freedom, as distinguished from the followers of Rousseau. Montesquieu passed the latter part of his life alternately at La Brède and Paris. Among his minor writings are academical discourses; the Dialogue de Sylla et d'Eucrate, an explanation of the political conduct of Sulla; the Temple de Glaive, a romance of classical antiquity; and an Essai sur le goôt, written for the Encyclopédie. The most complete editions of his works are those of Lefèvre (6 vols., Paris, 1816) and Lequien (8 vols., 1819, and with the éloges by D'Alembert and Villemain, 1827). A new edition of Nugent's translation of the "Spirit of the Laws," with D'Alembert's memoir of Montesquieu, was published in Cincinnati in 1873.

**Montevideo, Gaudí**, an Italian composer, born in Cremona about 1555, died in Venice in 1649. He composed both secular and ecclesiastical music, but was particularly celebrated for his motets and madrigals, of the latter of which he produced five books. **Montevideo**, a city, capital of Uruguay, South America, and of the department of its own name, on the N. shore of the estuary of the Rio de la Plata, 180 m. E. S. E. of Buenos Ayres, in lat. 34° 53' S., lon. 56° 15' W.; pop. in 1872, 105,296. It is built on a gentle elevation, at the extremity of a tongue of land jutting into the bay, and is defended by a citadel mounting 20 guns. It comprises two divisions, the old and the new town, between which traces of the old wall are still visible. A mountain in the rear, to which it owes its name, is surmounted by an antique Spanish castle. The streets are very regular, well paved, and lighted with gas. The houses are substantial; many of them have two and even three stories. Excellent water is brought from a distance of 34 m. The principal square, with an area of two acres, is tastefully planted with trees and flowers, and has a superb fountain. On the S. side is the parish church, with turrets 225 ft. above the level of the bay; and on the N. side is the cabildo, containing the law courts, senate house, and prison. The government
house is a miserable edifice. The old market, once the citadel of Montevideo, and a complete fortress in itself, is the most interesting relic of the colonial period; it was erected by 2,000 Guaraní Indians, who worked seven years without pay. It is now a sort of bazaar, and serves as a barrack for troops in revolutionary times. The custom house is a fine building of modern style, 900 by 300 ft. The post office is one of the best appointed in South America; and the average number of letters and papers passing through it annually is 2,000,000. Facing the post office are the museum and the library, containing 3,653 volumes. The exchange, of modern construction, ranks among the finest public buildings on the southern continent; it cost $160,000. There are, besides, the cathedral, six churches and chapels, several convents, and an Episcopal and a Methodist church. The educational establishments comprise a university, schools for mechanics, law, and other sciences, 33 public and 54 private schools, with an aggregate attendance of 10,048. The institute of public instruction is a sort of volunteer committee for the diffusion of useful knowledge. There are four large markets, six banks, savings banks, numerous clubs, mercantile associations, three theatres, a bull ring, and several ball and concert rooms. An immigrants' asylum affords adequate protection to thousands every year. The total number of immigrants landed at Montevideo in 1856 was 6,000; in 1858, 8,550; in 1865, 17,381; and in 1872, 20,000, probably including many who afterward proceeded to Buenos Ayres. The city has several prisons and a house of correction for females called los ejercicios. Besides the public hospitals, there are charitable institutions under the direction of the sisters of mercy, an orphan asylum, a home for the poor, and a lunatic asylum. There are three cemeteries, one of which is British. The city is the cleanest and healthiest in South America; and the suburbs, watering places, and surrounding country are extremely picturesque. The bay of Montevideo resembles a horse shoe in shape; it is about 4 m. long and 2 m. broad, but has only from 14 to 19 ft. of water, having diminished 5 ft. since the beginning of this century; but the bottom is soft, and vessels receive no damage by grounding. It can conveniently anchor 500 ships drawing 15 ft.; but it is open to the S. S. W. winds. All vessels receive and discharge their cargoes by means of launches. There are two dry docks with every facility for repairing ships. The trade of Montevideo is very considerable. The exports consist chiefly of salt beef, hides, hair, tallow, wool, bones, bone ashes, &c.; copper is brought overland from Chili and sometimes shipped here, as well as maté or Paraguay tea. The principal imports are cottons, woollens, hardware, flour, wine, spirits, sugar, tobacco, salt, boots, &c. The imports from the United States are flour, chairs, refined sugar, whiskey, cordage, agri-

The value of the imports for 1873 was estimated at $22,500,000. The custom-house receipts in 1872 amounted to $6,417,812, and in 1873 to $6,478,209. The port movements for the same year were: entered, 1,617 vessels, tonnage 877,668; cleared, 1,609, tonnage 908,697. About 60 of the vessels were under the United States flag, and 253 were British steamers. Six British mail steamers visit the port monthly, besides four French packets, three Italian, two Brazilian, and one Anglo-Belgian. The coasting trade averages 2,000 entries annually. The city is connected by railway with Florida, 72 m. distant; a branch line to Colonia was to be commenced in 1874; and a fine eastward was in course of preparation. Four lines of street horse cars are in operation. Montevideo is in telegraphic communication with Buenos Ayres, the chief towns of the interior, and the Brazilian system. The commercial and industrial establishments number 5,663, comprising 3 steam saw mills, 8 foundries, 93 factories, 13 tanneries, 62 brick kilns, 7 steam flour mills, and 9 abattoirs, in which last upward of 300,000 head of cattle are slaughtered yearly.—Montevideo (or with its full name, San Felipe de Montevideo) was founded in 1717 by the viceroy Lavala; but it remained a mere military outpost till 1726, when Francisco Alcubiar introduced the first settlers from the Canaries. In 1778 it was by royal decree declared a port, and its population and commerce rapidly increased. The city was fortified by the Spaniards in 1777. In February, 1807, it was besieged and taken by the British, who were expelled in July. After the independence of the Plate Provinces in 1811, the Brazilians seized it, but were forced to surrender it after a long siege in 1814. They retook it in 1817; and in 1825 it regained its independence by treaty, and was made the capital of Uruguay. (See URUGUAY.)

MONTEZUMA, Lobs. See LOLA MONTEZ.

MONTEZUMA (Mex. Monteapamatlin, the sad or severe man), the name of two emperors of ancient Mexico.—Montezuma I, born about 1390, died in 1464. He served as general under his uncle, who preceded him on the throne. After his accession in 1430 or 1438 he made war upon the kingdom of Chalco in defence of
his allies the Tezcuays. The Chalcos were routed in a great battle, and their chief city was entirely destroyed. A war followed with the king of Tlatelolco, who was defeated and killed. Montezuma next conquered the province of Cuilixcas, and subsequently that of Tzompahuacan. In a war with Atonalitzín, a chief of the Mixtecas, he suffered reverses which led to a confederacy between Atonalitzín and the Huezotzincas and Tlascalans against the Mexicans; but Montezuma in his first encounter with them gained a signal victory, which greatly enlarged his empire. In 1457 he conquered Cuetlachan, a province on the Mexican gulf, and carried 6,200 of the people to Mexico, where they were sacrificed to the god of war.—Montezuma II., the last of the Aztec emperors, born about 1490, succeeded his uncle Ahuitzotl in 1502, and was killed June 30, 1520. He was both a soldier and a priest, and had taken an active part in the wars against the Spaniards. When his election to the imperial dignity was announced to him, he was sweeping the stairs of the great temple of Mexico. At the commencement of his reign he led a successful expedition against a rebellious province, and brought back a multitude of captives to be sacrificed at his coronation. For several years he was constantly at war, and his campaigns, which extended as far as Honduras and Nicaragua, were generally successful. He made important changes in the internal administration of the empire, especially in the courts of justice, and became noted for strictness and severity in the execution of the laws, as well as for munificence to those who served him and in his expenditures for public works. He became equally noted also for arrogance, pomp, and luxury, and his heavy taxes led to many revolts. At the time of the arrival of Cortes in Mexico in 1519, Montezuma was alarmed not only by the internal troubles of his empire, but by the appearance of comets and other strange lights in the sky, and of mysterious fires in the great temple, which the seers interpreted as omens of the approaching downfall of the empire. Thus disheartened, he did not meet the invasion of the Spaniards with his usual energy. He at first forbade the white men to approach his capital, and then sent an embassy to welcome them. When Cortes entered Mexico (Nov. 8) he was received by Montezuma with courtesy and apparent good will, and at first treated the emperor with the greatest deference; but a collision between the Mexicans and a Spanish garrison at Vera Cruz soon afforded a pretext for a change of measures. At the end of a week after his arrival he waited upon Montezuma with a few of his officers under pretence of a friendly visit, and, after upbraiding him with the transactions at Vera Cruz, took him captive, and carried him to the Spanish headquarters. The emperor, fearing instant death if he made any opposition, assured his subjects, who were about to attempt a rescue as he passed through the streets, that he accompanied the Spaniards of his own free will. Montezuma was for a while put in irons, and was so completely humbled that when Cortes offered to liberate him, he declined to return to his palace, apparently ashamed to be seen by his nobles. He was subsequently induced to swear allegiance to the king of Spain, and was kept a prisoner for seven months, till in June, 1520, the people of the capital rose in insurrection and besieged the Spaniards in their quarters. He was induced by Cortes to address his subjects from the battlements of his prison in hopes of appeasing the tumult; but though at first listened to with respect, his appeals in behalf of the white men at length exasperated the Mexicans; a shower of missiles was discharged at him, a stone struck him on the temple, and he fell senseless. He refused all remedies and nourishment, tore off the bandages, and died in a few days. Some of the oddments of Montezuma became Christians, and were carried to Spain. From them descended the counts of Montezuma, one of whom was viceroy of Mexico from 1697 to 1701.

Montfaucon, Bernard de, a French scholar, born at Soulange, Languedoc, Jan. 13, 1655, died in Paris, Dec. 21, 1741. He belonged to a noble family, and after completing his education at the college of Limoux, he served in two campaigns in Germany under Turenne, and in 1675 entered a Benedictine convent at Toulose. Afterward he went to Paris, where he became a member of the congregation of St. Maur, and acquired a high reputation for his scholarly attainments. In 1719 he was made a member of the academy of inscriptions. His most important works are: Paleographie Gracce, sive de Ortu et Progressu Literarum Gracarum (fol., Paris, 1708); L'antiquite expliquée et représentée en figures (in French and Latin, 10 vols. fol., 1719; supplement, 5 vols. fol., 1724); and Les monuments de la monarchie francaise (in French and Latin, 5 vols. fol., 1729-33). He also published valuable editions of the works of several of the Greek fathers.

Montferrat (Ital. Monferrato), a territory of Italy, formerly an independent duchy, bounded N. and W. by Piedmont, S. by Genoa, and E. by Milan. It was separated by a strip of Milanese territory into the divisions of Casale on the north and Acqui on the south, Casale being the capital. It often changed masters, and for more than a century was in the hands of the dukes of Mantua; but in 1703 it was bestowed by the emperor Leopold I. upon the duke of Savoy, a possession of whose house it has since remained. The territory is now divided among the provinces of Alessandria, Genoa, Coni, Turin, and Novara. The family of Montferrat was of remote origin, and very conspicuous in the march of events.

Montfort, Jean (IV.), duke of Brittany, born in 1293, died in Hennebon, Sept. 26, 1345. He was the son of Duke Arthur II., and succeeded his brother Jean III. in 1341.
latter had bequeathed the duchy to Charles of Blois, husband of his niece; but Montfort found little difficulty in getting possession, and Charles complained to the king, Philip of Valois, who sent an army to besiege the usurper in Nantes. In order to save the city from assault, Montfort surrendered and was carried prisoner to Paris; but in the mean time his wife, Jeanne of Flanders, put herself at the head of his partisans and withdrew to Hennebon, where she defended herself against the forces of Charles, on one occasion repelling an assault at the head of 300 cavaliers. The arrival of auxiliaries sent by Edward III. of England, to whom Montfort had done homage for Brittany, obliged Charles to raise the siege. A second attempt upon the same city in 1342 was equally unsuccessful, and Charles soon lost successively Guérande, Vannes, Carhaix, and Quimperle. In the same year Edward III. arrived in France with fresh troops and advanced to Rennes, where Philip marched out to meet him. By the mediation of the pope a truce was concluded between the monarchs. Montfort's party, which before was barely a match for his rival's, had grown during his imprisonment. He escaped in disguise in 1345, and went to England, whence he returned with troops and made an unsuccessful attempt upon Quimper. He then retired to Hennebon, where he died a few weeks afterward, leaving a son who continued the war with Charles, and became duke as Jean V.

Montfort. I. Simon de, a French soldier, born about the middle of the 12th century, slain before Toulouse, June 25, 1218. He engaged in the fourth crusade, but when he saw the enterprise diverted from its legitimate object he declined to follow its chief to Constantinople, and to fulfil his vows went by himself to Palestine. On his return he took up arms again at the summons of Pope Innocent III., and in 1208 was elected leader of the crusade waged against the Albigenses of southern France, whom he mercilessly pursued and slaughtered. On the taking of Béziers (1209) more than 20,000 of its inhabitants were put to death by his permission, if not by his orders. Carcassonne was scarcely better treated; the viscount of Béziers, who commanded there, was made prisoner in an interview for negotiation; the town was forced to surrender, and many of its citizens were sentenced to death as heretics. At Lavanir, Aimery of Montreal was hanged, 80 knights were put to the sword, hundreds of poor people burned at the stake, and the lady of the castle, Aimery's sister, was thrown alive down a well, and stones were heaped over her. Montfort ruled despotically over the territories which he had wrested from Count Raymond of Toulouse in this war; and when Pedro II., king of Aragon, came to protect the latter, as his lord paramount, the crusader met him, Sept. 12, 1213, and defeated and killed him under the walls of Muret. Montfort was then proclaimed count of Toulouse. Raymond's son finally managed to re-enter Toulouse, where he had many adherents. Montfort besieged that city for eight months, and when attempting to storm it was killed by a stone thrown from the wall. His elder son, Amaury, succeeded him as count of Toulouse, afterward became grand constable of France, and died in 1241 on his return from Palestine. II. Simon de, earl of Leicester, younger son of the preceding, the leader of the English barons in the reign of Henry III., born about 1200, killed Aug. 4, 1265. He went with the English in 1251 to escape the enmity of Blanche of Castile, queen regent of France, and gained the favor of the king, who bestowed upon him the earldom of Leicester, the governorship of Gascony, and the hand of his own sister Eleanor, countess dowager of Pembroke. He governed Gascony with an iron hand, and made his power particularly felt by the native lords, but was popular with the English. In England he became the head of the barons who conspired to curtail the king's prerogative. Henry III., having convoked a parliament in 1258, Montfort appeared in arms with his confederates, and constrained the king to sign the provisions of Oxford, by which the whole legislative and executive power was thrown into the hands of 24 barons, who were controlled by Montfort. An agreement was proposed between the nobles and the king through the arbitration of Louis IX. of France; but his award not being acceptable to either, both parties took arms. In May, 1264, Montfort defeated the royal army at Lewes in Sussex, and captured the king. In January, 1265, he summoned a parliament, in which, for the first time on record, representatives of boroughs were admitted. His power was now at its height, but his overbearing conduct excited discontent even among the adherents of the national cause; and the king's son, Prince Edward, who was kept as a hostage, having made his escape, many of his former opponents joined his standard. Montfort was defeated in battle by superior numbers, and was slain with one of his sons and many barons, while his army was completely routed. The family of Montfort was expelled from England.

Montgolfier. See Aeronautics.

Montgomery, the name of counties in 18 of the United States. 1. An E. county of New York, intersected by the Mohawk river, which is here joined by the Schoharie and other smaller streams; area, 356 sq. m.; pop. in 1870, 34,457. It has a fertile soil, especially in the valley of the Mohawk. The Erie canal and the New York Central railroad pass through it. The chief productions in 1870 were 61,659 bushels of wheat, 175,654 of Indian corn, 662,516 of oats, 86,665 of barley, 100,769 of buckwheat, 194,041 of potatoes, 717,277 lbs. of hops, 58,847 of wool, 1,174,523 of butter, 1,514,482 of cheese, 21,170 bushels of peas and beans, and 104,898 tons of hay. There were 7,606 horses, 26,917 milk cows, 8,557 other...
cattle, 12,884 sheep, and 6,773 swine; 2 manufactories of agricultural implements, 10 of bows, and brushes, 1 of carretts, 21 of cheese, 9 of hosiery, 1 of forged and rolled iron, 6 of iron castings, 3 of malt, 1 of linseed oil, 1 of washing machines, 1 of woolen goods, 10 tanneries, 16 saw mills, and 13 flour mills. Capital, Fonda. II. A S. E. county of Pennsylvania, bounded S. W. by the Schuykill river; area, 450 sq. m.; pop. in 1870, 51,612. The surface is undulating and the soil is rich, especially along the Schuykill. It is intersected by the Philadelphia, Germantown, and Norristown, the Philadelphia and Reading, the Northern Pennsylvania, and other railroads. The chief productions in 1870 were 340,911 bushels of wheat, 150,158 of rye, 1,026,865 of Indian corn, 791,272 of oats, 456,945 of potatoes, 3,104,748 lbs. of butter, 195,057 of cheese, and 112,287 tons of hay. There were 13,281 horses, 31,179 milch cows, 6,687 other cattle, 3,623 sheep, and 18,931 swine; 11 manufactories of agricultural implements, 20 of brick, 54 of carriages and wagons, 1 of coal oil, 8 of cotton goods, 12 of furniture, 10 of forged and rolled iron, 3 of nails and spikes, 6 of pig iron and 6 of castings, 19 of lime, 6 of machinery, 2 of linseed oil, 8 of stone and earthen ware, 46 of turned and planed wood, 13 of woolen goods, 15 tanning and currying establishments, 44 flour mills, and 13 saw mills. Capital, Norristown. III. A central county of Maryland, bounded N. E. by the Patuxent, and S. W. by the Potomac river; area, 440 sq. m.; pop. in 1870, 20,563, of whom 7,434 were colored. The surface is moderately uneven; the soil is fertile along the banks of the rivers. It is traversed by the Metropolitan branch of the Baltimore and Ohio railroad, and the Chesapeake and Ohio canal passes along the S. W. border. The chief productions in 1870 were 308,418 bushels of wheat, 25,341 of rye, 63,040 of sweet potatoes, 171,242 of oats, 179,582 of potatoes, 630,000 lbs. of tobacco, 17,880 of wool, 188,334 of butter, and 12,735 tons of hay. There were 5,211 horses, 4,691 milch cows, 5,448 other cattle, 6,812 sheep, and 13,267 swine. Capital, Rockville. IV. A S. W. county of Virginia, bounded W. by New river and drained by the head waters of Staunton river; area, 490 sq. m.; pop. in 1870, 12,558, of whom 2,882 were colored. The surface is mountainous and the soil generally rocky, but productive near the rivers. The Atlantic, Mississippi, and Ohio railroad passes through it. The chief productions in 1870 were 100,761 bushels of wheat, 16,252 of rye, 144,723 of Indian corn, 78,168 of oats, 12,373 of potatoes, 204,747 lbs. of tobacco, 13,737 of wool, 159,212 of butter, and 4,106 tons of hay. There were 1,807 horses, 2,240 milch cows, 4,033 other cattle, 4,966 sheep, and 8,089 swine. Capital, Christiansburg. V. A S. county of North Carolina, bounded W. by Yadkin river, and drained by its branches; area, 500 sq. m.; pop. in 1870, 7,487, of whom 2,129 were colored. The surface in the west is hilly, and much of the soil is fertile. The chief productions in 1870 were 50,478 bushels of wheat, 118,589 of Indian corn, 39,177 of oats, 22,155 of sweet potatoes, 13,992 lbs. of tobacco, 23,782 of wool, 76,034 of butter, and 632 bales of cotton. There were 1,144 horses, 2,278 milch cows, 3,495 other cattle, 8,320 sheep, and 9,583 swine. Capital, Lawrenceville. VI. A S. E. county of Georgia, bounded N. E. by Pendleton's river, S. by the Altamaha, and S. W. by the Little Ocmulgee, and intersected by the Oconee; area, 624 sq. m.; pop. in 1870, 3,586, of whom 1,108 were colored. The surface is level and the soil sandy. The chief productions in 1870 were 70,405 bales of Indian corn, 15,852 of oats, 11,437 of sweet potatoes, 21,553 lbs. of wool, 10,261 of butter, 391 bales of cotton, and 5,309 gallons of cane molasses. There were 589 horses, 3,339 milch cows, 9,222 other cattle, 9,853 sheep, and 9,246 swine. Capital, Mount Vernon. VII. A S. E. county of Alabama, bounded N. W. by the Alabama and Coosa rivers, and N. by the Tallapoosa; area, about 800 sq. m.; pop. in 1870, 45,704, of whom 31,285 were colored. The surface is uneven and the soil generally fertile. Several railroads centre at Montgomery, an area, 1,108 square miles, and Girard crosses the S. E. corner. The chief productions in 1870 were 602,549 bushels of Indian corn, 25,648 of sweet potatoes, 25,517 bales of cotton, 3,753 lbs. of rice, and 1,599 gallons of cane molasses. There were 1,923 horses, 4,250 mules and asses, 3,027 milch cows, 5,569 other cattle, 980 sheep, and 13,909 swine; 2 flour mills, 4 saw mills, 2 founderies, and 2 railroad repair shops. Capital, Montgomery, which is also the capital of the state. VIII. A N. central county of Mississippi, drained by Big Black river, formed since the census of 1870 from Carroll and Choctaw counties, of which 1,026,779 acres are Indian country; the soil is gently undulating, and the soil productive. It is traversed by the Mississippi Central railroad. Capital, Winona. IX. An E. county of Texas, drained by San Jacinto river and its tributaries; area, 852 sq. m.; pop. in 1870, 6,458, of whom 3,351 were colored. It has a rolling surface, with an abundance of good timber, and the soil, with the exception of some sandy pine barrens, is fertile. The Houston and Great Northern railroad passes through it. The chief productions in 1870 were 163,290 bushels of Indian corn, 4,945 of sweet potatoes, and 3,485 bales of cotton. There were 1,029 horses, 4,184 milch cows, 10,857 other cattle, 1,406 sheep, and 13,944 swine. Capital, Montgomery. X. A W. county of Arkansas, drained by Washita river and its branches; area, 1,050 sq. m.; pop. in 1870, 2,984, of whom 120 were colored. The surface is mostly mountainous. The chief productions in 1870 were 3,072 bushels of wheat, 93,739 of Indian corn, 2,596 of oats, 273 bales of cotton, 3,044 lbs. of tobacco, 2,051 of wool, 19,252 of butter, 2,007 of honey, and 2,055 gallons of sorghum molasses. There
MONTGOMERY

were 570 horses, 945 milk cows, 1,756 other cattle, 1,318 sheep, and 5,762 swine. Capital, Mount Ida. XI. A N. W. county of Tennessee; bordering on Kentucky, and drained by Cumberland river and its branches; area, 500 sq. m.; pop. in 1870, 24,747, of whom 11,670 were colored. The Louisville, Nashville, and Great Southern railroad traverses it. The chief productions in 1870 were 174,525 bushels of wheat, 810,194 of Indian corn, 62,575 of oats, 25,403 of Irish and 35,400 of sweet potatoes, 4,856,789 lbs. of tobacco, 14,009 of wool, and 217,981 of butter. There were 3,023 horses, 2,569 mules and asses, 3,272 milk cows, 4,283 other cattle, 8,015 sheep, and 28,205 swine; 13 flour mills, 10 saw mills, 4 tanneries, 6 distilleries, and 1 woolen mill. Capital, Clarksville.

XII. A N. E. county of Kentucky; area, 275 sq. m.; pop. in 1870, 7,557, of whom 2,699 were colored. The surface is hilly and mountainous, and most of the soil fertile. The Mount Sterling division of the Louisville, Cincinnati, and Lexington railroad terminates at the county seat. The chief productions in 1870 were 611,651 bushels of wheat, 10,259 of rye, 542,710 of Indian corn, 43,945 of oats, 16,285 of potatoes, 17,902 lbs. of wool, 87,424 of butter, and 2,387 tons of hay. There were 2,660 horses, 1,402 mules and asses, 1,977 milk cows, 8,606 other cattle, 5,215 sheep, and 12,641 swine. Capital, Mount Sterling.

XIII. A S. W. county of Ohio, drained by Miami river and its branches; area, 480 sq. m.; pop. in 1870, 64,006. The surface is undulating, and the soil generally fertile. Trenton limestone is abundant. The Miami canal passes through it, and several railroads terminate at Dayton. The chief productions in 1870 were 824,008 bushels of wheat, 1,088,781 of Indian corn, 409,804 of oats, 83,002 of barley, 142,425 of potatoes, 45,197 of flax seed, 636,300 lbs. of flax, 3,983,183 of tobacco, 23,047 of wool, 650,526 of butter, and 19,301 tons of hay. There were 9,153 horses, 8,775 milk cows, 7,925 other cattle, 7,095 sheep, and 25,761 swine; 14 manufactories of agricultural implements, 17 of brick, 34 of carriages and wagons, 2 of cotton goods, 2 of dressed flax, 14 of machinery, 8 of stone work, 7 of linseed oil, 13 of saddlery and harness, 4 of sash, doors, and blinds, 2 of woollen goods, 16 iron founders, 13 tanneries, 8 distilleries, 11 breweries, 22 saw mills, 4 planing mills, and 25 flour mills. Capital, Dayton.

XIV. A W. county of Indiana; area, 504 sq. m.; pop. in 1870, 23,765. The surface is level or undulating, and the soil is generally good. The Louisville, New Albany, and Chicago, and the Indianapolis, Bloomington, and Western railroads pass through it. The chief productions in 1870 were 706,172 bushels of wheat, 1,004,706 of Indian corn, 83,500 of milk cows, 69,409 of potatoes, 149,829 lbs. of wool, 391,403 of butter, and 18,104 tons of hay. There were 9,466 horses, 6,590 milk cows, 15,721 other cattle, 37,533 sheep, and 34,879 swine; 7 manufactories of furniture, 7 of brick, 10 of carriages, 6 of cooperage, 1 of iron castings, 2 of machinery, 7 of saddlery and harness, 4 of woolen goods, 1 pork-packing establishment, 23 saw mills, 1 planing mill, and 21 flour mills. Capital, Crawfordsville.

XV. A S. W. county of Illinois; area, 544 sq. m.; pop. in 1870, 25,314. It has a diversified surface, partly covered with forests, and a rich soil. The Indiana-apolis and St. Louis and the Toledo, Wabash, and Western railroads pass through it. The chief productions in 1870 were 744,950 bushels of wheat, 1,027,898 of Indian corn, 665,424 of oats, 66,515 of potatoes, 54,608 lbs. of wool, 275,794 of butter, and 29,871 tons of hay. There were 12,447 horses, 6,400 milk cows, 7,510 other cattle, 12,881 sheep, and 34,778 swine; 7 manufactories of carriages, 1 of cars, 3 of cooperage, 5 of furniture, 1 of iron castings, 2 of machinery, 10 of saddlery and harness, 2 of woolen goods, 9 saw mills, 2 breweries, and 12 flour mills. Capital, Hillsborough.

XVI. A S. W. county of Iowa, drained by Nishnabotana and West Nodaway rivers, tributaries of the Missouri; area, 432 sq. m.; pop. in 1870, 5,834. The surface is undulating and the soil fertile. The Burlington and Missouri river railroad and its Red Oak branch pass through it. The chief productions in 1870 were 59,712 bushels of wheat, 320,168 of Indian corn, 37,393 of oats, 23,991 of potatoes, 18,492 lbs. of wool, 87,220 of butter, and 9,979 tons of hay. There were 1,461 horses, 1,256 milk cows, 2,475 other cattle, 4,503 sheep, and 10,287 swine; 7 flour mills, and 3 lumber mills. Capital, Frankfort.

XVII. An E. county of Missouri, bounded S. by the Missouri river; area, 576 sq. m.; pop. in 1870, 10,465, of whom 939 were colored. The surface is hilly in the region of the river, and in other parts undulating. Limestone, iron ore, and coal are found. The St. Louis, Kansas City, and Northern railroad passes through it. The chief productions in 1870 were 74,150 bushels of wheat, 548,112 of Indian corn, 297,035 of oats, 203,170 lbs. of tobacco, 38,083 of wool, 16,973 of butter, and 6,740 tons of hay. There were 3,375 horses, 2,943 milk cows, 5,214 other cattle, 10,350 sheep, and 14,041 swine. Capital, Daviess.

XVIII. A S. E. county of Kansas, bordering on Indian territory, and intersected by Verdigris river; area, 624 sq. m.; pop. in 1870, 7,564. It is traversed by the Leavenworth, Lawrence, and Galveston railroad. The surface consists of rolling prairies, and the soil is fertile. The chief productions in 1870 were 12,665 bushels of Indian corn, 1,443 of potatoes, and 1,553 tons of hay. There were 1,029 horses, 1,595 milk cows, 4,090 other cattle, 674 sheep, 1,065 swine, and 8 saw mills. Capital, Independence.

MONTGOMERY, a city of Montgomery co., Alabama, capital of the county and state, and the second city of the state in population and importance, situated on a high bluff on the left bank of the Alabama river, about 300 m. above Mobile, in lat. 32° 22' N. and lon. 86° 23' W.; pop. in 1860, 8,843; in 1870, 10,588, of whom 5,183 were colored. The river is navigable to
this point by steamers at all seasons, and four lines of railroad furnish means of communication with all sections of the state, viz.: the Mobile and Montgomery; Montgomery and Enfauta; South and North Alabama; and Western of Alabama. The city is the point of supply and shipment of a large and fertile cotton region. Its trade in groceries is important, and its receipts of cotton are large. The entire trade amounts to nearly $10,000,000 a year. The chief manufacturing establishments are an iron foundry and a flouring mill. There are two national banks, with a joint capital of $425,000, and three private banking houses. The state house, which occupies an elevated situation on Capitol hill, was erected in 1851 at a cost of $75,000, the original capitol having been destroyed by fire in 1849. The dome commands a fine view of the city and adjacent country. Among other public buildings are the court house, a fine city hall containing a market and rooms for the fire department, and the theatre. The city is lighted with gas, and supplied with water by artesian wells and water works (from the river) of sufficient capacity to keep in reservoir three months' supply for 25,000 people. The public schools are attended by about 800 white and 500 colored children, and there are several private schools, with a large attendance. Three daily newspapers (issuing also weekly editions) and a weekly agricultural journal are published. There are 14 churches, viz.: 4 Baptist (2 colored), 1 Episcopal, 1 Jewish, 5 Methodist (2 colored and 1 Northern), 1 Presbyterian, 1 Protestant Methodist, and 1 Roman Catholic. —Montgomery was laid out in 1817, and the seat of government was removed to it from Tuscaloosa in 1847. It was the seat of the confederate government from Feb. 4, 1861, to the following May, when it was removed to Richmond. The city was evacuated by the confederates April 11, 1865, after burning 80,000 bales of cotton, and on the following day it was occupied by the federal forces under Gen. Wilson, when the arsenal, railroad depots, and foundry were destroyed.

MONTGOMERY, James, a British poet, born in Irvine, Ayrshire, Nov. 4, 1771, died near Sheffield, April 30, 1854. His father was a Moravian preacher, and James, being intended for the same office, was sent in his seventh year to a Moravian settlement at Fulneck, near Leeds, to complete his education. Here he remained ten years, distinguished only for indolence and melancholy. The brethren at Fulneck then apprenticed him to a grocer in Mirfield. Before the age of 14 he had written a mock heroic poem of 1,000 lines, and had commenced an epic to be called "The World." He ran away in June, 1789, but after many wanderings engaged again as shop boy in Wath, a village of Yorkshire. A year later he sent a volume of manuscript poetry to Mr. Harrison, a London publisher, and soon after went to London himself. Harrison refused his poems, but engaged him as his shopman. Toward the end of 1792 he became clerk to Joseph Gales, editor and publisher of the "Sheffield Regis- ter," a newspaper of revolutionary tendencies. Gales fled to America to avoid arrest for treason, and Montgomery started a new weekly journal called the "Sheffield Iris," advocating peace and reform principles. The first number appeared July 4, 1794, and he edited it till Sept. 27, 1825. Almost immediately after the first appearance of the "Iris," he was fined £20, and sentenced to three months' imprisonment, for printing a doggerel ballad on "The Fall of the Bastile" for a poor hawker. Again in 1790 he was found guilty of sedition, fined £20, and sentenced to six months' imprisonment for publishing in his newspaper an account of a riot in Sheffield. He was confined in York castle, where he wrote a small volume of poems entitled "Prison Amusements," published in 1797. His gentle yet earnest character, and his literary ability, gradually won him the regard of his political opponents, and he began to take a high rank as a sacred poet. In 1806 he published "The Wanderer of Switzerland," in 1810 "The West Indies" and "Greenland," and in 1819 "The World before the Flood," which attained great popularity. In 1835 a
pension of £150 was bestowed on him by the queen. He was a liberal whig, and an ardent slavery abolitionist, and in his manhood reunited himself with the Moravians. Besides the works mentioned, he published "The Pelican Island, and other Poems" (1827), and "Original Hymns" (1853); and in prose, "Lectures on Poetry and General Literature, delivered at the Royal Institution in 1850 and 1851" (1856). Collected editions of his poetical works were published in 6 vols. in 1836, 4 vols. in 1841 and 1855, and 1 vol. in 1850 and 1855. Memoirs, with correspondence and journals (7 vols. 8vo, 1855-'6), were published by John Holland and James Everett.

MONTGOMERY, Richard, an American general, born near Raphoe, Ireland, Dec. 2, 1736, killed in the attack on Quebec, Dec. 31, 1775. At the age of 18 he obtained a commission in the British army. He was at the siege of Louisburg in 1758, distinguished himself in the expeditions against Martinique and Havanna, and in 1762 revisited Europe. In 1772 he emigrated to New York, married a daughter of Judge Robert R. Livingston, and in 1773 settled in Rhinebeck. In 1775 he represented Dutchess county in the provincial congress, and in the same year was appointed brigadier general in the army of the united colonies, and was attached as senior brigadier to the larger of the two divisions sent to Canada in the summer. The illness of Gen. Schuyler threw the command of the division upon Montgomery, who successively acquired possession of Chambly, St. John's, and Montreal, thereby becoming in the middle of November master of a great part of Canada. Effecting a junction on Dec. 4 with Arnold's troops, he immediately took a position before Quebec. On Dec. 9 he was made a major general. It was determined to attempt to capture the place by a coup de main, and on Dec. 31, at 2 A.M., Montgomery headed the attack on the upper town. He reached the first barrier, which was quickly carried, pressed eagerly on to the second, and with his two aides fell dead at the first and only discharge by the British artillerymen, his troops retreating in disorder. Congress erected a monument to him in the front of St. Paul's church, New York. In 1818 the state of New York caused his remains to be removed and placed beneath the monument.

MONTGOMERY, Robert, an English poet, born in Bath in 1807, died in Brighton, Dec. 8, 1855. He was the son of a theatrical clown named Gomery, and assumed the name of Montgomery. He early conducted "The Inspector," a weekly journal in Bath, and published "The Stage Coach," a poetical collection, "The Age Reviewed, a Satire" (1827), "The Omnipresence of the Deity," his most popular poem, and a volume of miscellaneous verses (1828), and "Satam" (1829). In 1830 he entered Lincoln college, Oxford, and in 1835 became curate of Whittington, Shropshire. Subsequently he was minister of Percy street chapel, London, and for a time of St. Jude's chapel, Glasgow. He published numerous works in addition to those mentioned, prominent among which were a series of "Meditations" upon Scripture subjects. His poems, for a time immensely popular, were subjected to a crushing criticism by Macaulay in the "Edinburgh Review" for April, 1830.

MONTGOMERYSHIRE, a county of Wales, bordering on the counties of Denbigh, Salop (England), Radnor, Cardigan, and Merioneth; area, 755 sq. m.; pop. in 1871, 77,789. It consists mostly of wild, rugged, and sterile moor, the highest of which is Plynlimmon, on the S. W. border of the county, its culminating peak, 2,481 ft. high, being just within the border of Cardiganshire. There are some fertile valleys, the best being that of the Severn, whose head waters traverse the county. The chief rivers, besides the Severn, are the Wrynwy, Yye, and Dovey. In the districts bordering on England agriculture has made considerable progress. Copper, zinc, coal, and limestone are mined. The staple manufactures are flannels, and a species of cotton called "Welsh plains." Capital, Montgomery.

MONTH (Sax. mona, the moon), a period of time defined by one revolution of the moon around the earth, and hence equal to 29 days, 12 hours, 44 minutes, and 3 seconds. This division of time, the lunar month, was used by the Chaldeans and Egyptians, and is still by the Jews, Turks, and many uncivilized nations, as the most distinctly marked period of the year. But if the year be made to comprise 12 of these months, the seasons will soon be found to fall back from those months to which they originally belonged, so that in 34 years each month would fall in each of the seasons. The civil year is divided into 12 months of an average length of 30 days, 10 hours, and 30 minutes. But these (called calendar months) are not equal, some (April, June, September, and November) consisting of 30, and the remainder of 31 days, except February, to which only 28 days are assigned, with the addition in leap years (every fourth year) of one more day. In popular language a month is often understood to be four weeks. This is even laid down by Blackstone as the legal definition of the term, so that a lease for 12 months is only for 48 weeks; but the expression "a twelvemonth" has been legally held to mean a solar year. In ecclesiastical and commercial matters, however, month always means a calendar month; and this is generally the legal meaning of the word in all relations in the United States.

MONTOLON, or Montholon-Sénonville, Charles Tristan, count and afterward marquis de, a French soldier, born in Paris, July 21, 1788, died Aug. 21, 1853. The son of a marquis, he became in 1798 a non-commissioned officer in a regiment of cavalry, and in less than two years reached the rank of chef d'escadron. He evinced great zeal in behalf of Bonaparte on the 18th Brumaire, and was afterward promo-
ted for his services in Italy, Germany, and Poland, especially distinguishing himself as aide-de-camp to Berthier, in the battle of Wagram (1809), after which he was made a count and attached to the personal staff of Napoleon. He was soon after appointed chamberlain to the emperor, and intrusted with several diplomatic missions. In 1814 he was made general of brigade, and became commandant of the department of the Loire. He joined the emperor on his return in 1815, acted as his aide-de-camp during the hundred days, fought for him to the last, and followed him to St. Helena. He witnessed his death, was appointed one of his executors, and returning to Europe published, in conjunction with Gen. Gour- gaud, Mémoires pour servir à l'histoire de France sous Napoléon, écrits à Ste. Hélène sous sa dictée (8 vols. Svo, Paris, 1823). His fortune having been ruined by his protracted absence, he tried to retrieve it by commercial enterprise, but became involved in debt and fled to Belgium. He was restored to the army after the revolution of 1830. He accompanied Prince Louis Napoleon in his attempt at Bou- logne in 1840, and shared his imprisonment at Ham, but at the end of a few years received a pension. While in prison he wrote Histoire de la capitaine de l'Empereur Napoléon à Ste. Hélène (Paris, 1847). After the revolution of 1848 he became a member of the legislative assembly.

MONTYON. See Montyon.

MONTI, Vincenzo, an Italian poet, born at Fusignano, near Ferrara, Feb. 19, 1754, died in Milan, Oct. 13, 1828. He was educated at Faenza and the university of Ferrara, where he read with enthusiasm the Latin and Italian poets, and before his 16th year published Latin elegies and an Italian poem on the prophecy of Jacob. The influence of Dante appears in his "La Vita di Cristo," written two years later. His verses attracted the attention of Cardinal Borghese, who conducted him to Rome. In 1778 he was appointed secretary to Braschi, nephew of Pope Pius VI. Assuming the clerical habit, he was called the abate Monti, though he never took orders. He became a member of the academy of Arcadians, with the principal members of which he was soon at war on account of his satires and impa- tience of criticism. In his drama Aristodemo he aimed to combine the vigor of Allieri with greater smoothness and elegance. A second, Galetto Manfredi, in which he violates his own principles of classicality, proved a failure. In 1793 he was selected by the pontifical government to celebrate the assassination of the French ambassador Bassville in a poem con-formed to their political views, and published in 15 days his Bassovilliana, which was the first effective expression of the horror of monarchi- cal and Catholic Europe at the French revolu- tion. The first edition of his mythological poem Musogonia (1790) was agreeable to the papal government; but he made Bonaparte the hero of the second edition (1798), and also of a still finer poem entitled Prometeo. He was successively secretary of the directory of the Cisalpine republic and commissary in the Romagna. He fled to France on the Austro-Russian invasion in 1799, but returned to Mil- lan after the battle of Marengo, and published the tragedy of Caio Gracco. Appointed profes- sor of belles-lettres in the college of Milan in 1803, he was immediately promoted to the chair of rhetoric in the university of Pavia. He celebrated in poems the leading events of Napoleon's career, and also made a translation of the Iliad, though he had studied Homer strictly through translators. His most important prose production was a philological work, in which he assailed the principles of the Della Cruscas. A complete edition of his works was published in 8 vols. (Bologna, 1825-'8), a select edition in 5 vols. (Milan, 1832-'4), and an edition in 6 vols. (Milan, 1839 et seq.).

MONTIGNY, Rose Marie Ozias Lemoine. See Cretel.

MONTLUCON, a town of France, in the depart- ment of Allier, on the Cher, and on the canal du Berry, 111 m. W. N. W. of Lyons; pop. in 1866, 18,675. It has ruins of an ancient castle and of old walls and towers, an industrial school, iron works, and extensive manufactory of mirrors, glass, glass, coarse woollens, and chemicals. It is connected by railway with Moulin, Bourges, and Limoges.

MONTMAGNY, a S. county of Quebec, Canadas, bounded N. W. by the St. Lawrence river be- low Quebec, and S. E. by Maine; area, 625 sq. m.; pop. in 1871, 13,555, of whom 13,449 were of French origin or descent. It is wa- tered by the Rivière du Sud and by the head streams of the St. John, and is traversed by the Grand Trunk railway. Capital, St. Thomas.

MONTMARTRE. See Paris.

MONTMELI (anc. Mons Median; mediaval, Mon-Malollet), a town and fortress of the fourth class of France, in the department of Mense, on the river Chiers and on the railway between Sedan and Thionville, 150 m. E. N. E. of Paris, 26 m. N. of Verdon, and 4 m. W. of the frontier of Luxemburg; pop. in 1866, 2, -35. It is divided into an upper and a lower town. The former, constituting the citadel of the place, is situated upon the summit and a steep rock, and is fortified with an enceinte having eight bastions, with outer works and a moat, protected by six demi-lunes. The lower town, called Bas-Médy, is surrounded by a strong fortification of eight bastions and three gates. The fortifications were in part planned by Van- ban, but have been greatly improved. The town is of little importance except in a mili- tary point of view. Montmédy, after having been several times attacked by detachments of the German army during September, 1870, and a sortie having been made from the lower town on Oct. 11, it was finally invested by a Prussian force, Nov. 16-28, and a bombardment was be- gun on Dec. 12. On Dec. 14, its commander, Maj. Tessier, surrendered the fortress, with
MONTMORENCY, a N. E. county of the S. peninsula of Michigan, watered by Black and Thunder Bay rivers; area, 576 sq. m.; returned as having no population in 1870. The surface consists of rolling table lands; the climate is severe, and the soil not fertile.

MONTMORENCY, an E. county of Quebec, Canada, bounded S. E. by the St. Lawrence, and drained by the Montmorency and St. Anne rivers; area, 2,183 sq. m.; pop. in 1871, 12,088, of whom 11,602 were of French origin or descent. It has an uneven surface and fertile soil. The isle of Orleans in the St. Lawrence river is included in the county. Capital, Château Richer.

MONTMORENCY, or Montmorenci, a river of the province of Quebec, Canada, which rises in Snow lake, Montmorency co., and flowing S., empties into the St. Lawrence, about 8 m. below Quebec. Just above its mouth it falls over a nearly perpendicular precipice a distance of 250 ft., with a width of 50 ft. About 15 m. above the falls the river has worn a series of natural steps in the limestone rock. At the foot of the falls a cone of ice is formed every winter, sometimes 200 ft. high. The falls of Montmorency are much resorted to by tourists and visitors from Quebec, and the drive to them from the city is very beautiful.

MONTMORENCY, a town of France, in the department of Seine-et-Oise, 7 m. N. of the enceinte of Paris; pop. about 3,500. It is on a hill commanding a fine view. There is a handsome Gothic church of the 14th or 15th century. The place is celebrated from the house near it called l'Ermitage, in which Jean Jacques Rousseau resided in 1756–8, and wrote his Nouvelle Héloïse. It was a peasant's house belonging to Mme. d'Épinay. It was afterward occupied by Grétry the composer, who died there in 1813. It now forms part of a large mansion; only the garden is as it was in Rousseau's time. Rousseau's Contrat social et Émile were also written in Montmorency, though not in the Hermitage. The town grew up around the château of Montmorency, built in 1108, no trace of which remains.

MONTMORENCY, a French feudal family, deriving its title from the château of the same name, and tracing its origin to the middle of the 10th century. Its members were styled "the first barons of France," or "the first Christian barons." Among them were six grand constables, twelve marshals, and four grand admirals of France, besides cardinals, grand masters, and knights of all European orders, and they intermarried several times with royal families. Two branches of the family established themselves in the Netherlands. Among their descendants were the count of Horn (Philip II. de Montmorency-Nivelle), executed by Egmont in Brussels, June 5, 1568; Floris de Montmorency, baron de Montigny, executed by order of Philip II., Oct. 14, 1570; and Marshal Luxembourg. The following are the chief historical characters of the French branch. I. Anne, first duke de Montmorency, born at Chantilly, March 15, 1492, died in Paris, Nov. 12, 1567. He distinguished himself first in the battle of Ravenna, in 1512. In 1515 he followed Francis I. to Italy, and fought bravely at Marignano. He exhibited great activity and firmness during the siege of Mézières in 1521, and for his gallantry in the disastrous battle of Bicoca, near Milan, in 1522, was created marshal. In 1524 he forced the constable de Bourbon to raise the siege of Marseilles. In 1525 he was made prisoner at the battle of Pavia, but was ransomed. He became governor of Languedoc and grand master of France in 1526, and was intrusted with the management of the finances. His avarice displeased the Genoese admiral Doris, who broke off his alliance with the king of France, and became one of the staunchest supporters of Charles V. In 1538 Montmorency laid waste Provence, which the imperial army had entered, and by prolonging the campaign nearly destroyed the enemy. Two years later he was made constable. In 1541 court intrigue forced his disgrace, and he retired to Chantilly; but after the death of Francis I. his influence at court became paramount. In 1548 he put down an insurrection in Guienne with cruel rigor. In 1551 his baronial estate was erected into a duchy by Henry II. He was defeated and taken prisoner at the battle of St. Quentin, Aug. 10, 1557, by Duke Phillibert Emanuel of Savoy, and, anxious to secure his release, was instrumental in bringing about in 1558 the disastrous peace of Cateau-Cambrésis. During the reign of Francis II. he lived in retirement; but he played a conspicuous part under Charles IX., and with the duke of Guise and Marshal Saint-André, with whom he formed a kind of triumvirate, was an uncompromising enemy of the Huguenots. At the battle of Dreux, Dec. 19, 1562, where he shared the command with his two colleagues, he was wounded and taken by the Protestants, although Guise won the day. Released by the peace of Amboise in 1563, he retook Havre from the English. In 1567, at the head of the Catholic army, he fought a drawn battle with the prince de Condé, near St. Denis, in which he was mortally wounded. II. Henri II., fourth and last duke de Montmorency, grandson of the preceding, born in Chantilly, April 30, 1596, executed in Toulouse, Oct. 30, 1632. Louis XIII. appointed him admiral of France before he was 17 years old. He succeeded his father as governor of Languedoc, fought against the Protestants, distinguished himself at the siege of Montauban and Montpellier, and in 1625 conquered the islands of Ré and Oléron. He now sold his office of admiral to Richelieu. Montmorency continued to oppose the duke de Rohan, who remained in arms for eight months after the taking of La Rochelle, and thus contributed to bring about the peace of Alais.
(1629), which terminated the last of the religious civil wars in France. In the same year he distinguished himself in Italy, and was finally made a marshal. After his return he joined Gaston of Orleans in his rebellion, and assembled his troops while Gaston was entering the kingdom from Lorraine at the head of a few thousand adventurers; but in the battle of Castelnauindy, Sept. 1, 1632, he was deserted by his ally and taken prisoner. He was sentenced to death by the parliament of Toulouse, and by order of Richelieu publicly beheaded in the great square. His life was written by Ducros, one of his officers (4to, 1633). III. Matthieu Jean Félicité, viscount and afterward duke de Montmorency-Laval, born in Paris, July 10, 1677, died there, March 24, 1826. He served in the American war, and was a deputy in 1789 to the constitutional assembly, where, during the famous night of Aug. 4, he was among the first to move for the spontaneous renunciation of feudal privileges and titles of nobility. Alarmed by the progress of the revolution, he emigrated in 1792, and returned in 1795, but kept aloof from politics, and lived on terms of intimate friendship with Mmes. de Staël and Récamier. He received no favors from Napoleon, but on the return of the Bourbons was appointed aide-de-camp to the count of Artois and peer of France, and on Dec. 24, 1821, minister of foreign affairs. He and Chateaubriand were the French plenipotentiaries at the congress of Verona, and on his return he was made governor to the infant duke of Bordeaux. Although he had no literary merit, he was elected in 1825 a member of the French academy. He died while at prayer in church.

MONTMORENCY, François de. See BOUTTEVILLE.

MONTOUR, an E. central county of Pennsylvania, intersected in the south by the N. branch of the Susquehanna river, and drained by Chillisquaque, Mahanouring, and Big Roaring creeks; area, 210 sq. m.; pop. in 1870, 15,344. Its surface is traversed E. and W. by baron ridges, including Montour's and Lime stone ridges and Muncy hills. There are several mines producing large quantities of iron. The valleys are fertile. It is traversed by the North Branch canal, and by the Catawissa railroad, passing through Danville. The chief productions in 1870 were 111,384 bushels of wheat, 176,941 of Indian corn, 179,518 of oats, 54,241 of potatoes, 192,048 lbs. of butter, and 10,142 tons of hay. There were 1,662 horses, 2,340 milch cows, 1,736 other cattle, 2,809 sheep, and 5,637 swine; 2 manufactories of forged and rolled iron, 5 of pig iron, 5 of castings, 2 breweries, 5 flour mills, 4 saw mills, and 8 tanneries. Capital, Danville.

MONTPELIER, a town of Washington co., Vermont, capital of the county and state, situated on the Onion river, here spanned by a substantial bridge, and on the Central Vermont and the Montpelier and Wells River railroads, 150 m. N. N. W. of Boston, in lat. 44° 17' N., lon. 72° 36' W.; pop. in 1870, 3,028. It is built on a plain near the centre of the state, and is surrounded by a highly cultivated hilly country. The principal village is compactly built. The state house is a fine edifice of light-colored granite, erected at a cost of $150,000 on the site of the former capital, which was burned in 1857. It stands on a slight eminence, approached from a common by granite steps in terraces. It is built in the form of a cross, the main building being 73 ft. long and each of the wings 52 ft. The main building is 113 ft. deep, and 124 ft. high to the top of the dome, which is surmounted by a graceful statue of Ceres. The court house is also a fine structure. Montpelier has an active trade with the surrounding country, and contains several flour mills, saw mills, tanneries, an iron foundery, an extensive machine shop, and manufactories of sash and blinds, carriages, cabs and sleds, hats and caps, furniture, &c. There are two banks, three insurance companies, one savings institution, three private schools, four weekly newspapers (two of which publish a daily edition during the session of the legislature), and seven churches. The state library contains 14,690 volumes. The town is the seat of the Vermont Methodist seminary and female college, organized in 1869. A history of Montpelier by D. P. Thompson was published in 1860 (8vo, Montpelier).
MONTPELLIER, a city of Languedoc, France, capital of the department of Hérault, near the Lz, 27 m. S. W. of Nîmes, 17 m. N. E. of Cette, its port, and 76 m. W. N. W. of Marseille; pop. in 1872, 57,727. It was once a place of military strength, but of its fortifications only the citadel remains. The town rises in the form of an amphitheatre along a slope, the summit of which, 185 ft. above the sea, is occupied by the place du Peyrou, a celebrated promenade. At the end of the promenade rises the château d’eau, which receives and distributes through the town the water conveyed from the opposite hill by an aqueduct of 53 large arches surmounted by 183 smaller ones, and 2,985 ft. long. The modernized cathedral contains an altarpiece, the “Fall of Simon Magus,” by Sébastien Bourdon, a native of Montpellier. The medical school, formerly the bishop’s palace, contains a library of 60,000 volumes, and portraits of the professors since 1289. The Musée Fabre, named after its founder, a Montpellier artist, contains a collection of paintings, the library of Allieri, of 15,000 volumes, and some important manuscripts connected with the Stuarts, which belonged to Prince Charles Edward. The botanical garden, the first established in France, dates from the reign of Henry IV. In place of the former university, founded in 1176, and the medical school of which was celebrated, there are now three faculties, of medicine, sciences, and literature. There is also a high school of pharmacy, a lyceum, an episcopal seminary, a normal school, and several other special schools. Montpellier has manufactures of woolens, printed cottons, linens, silks, leather, straw goods, wax, and brandy; and it is particularly celebrated for its vermiculite, made by oxidizing copper plates between layers of grape husks. There are also extensive manufactories of alum, Prussian blue, and sulphuric and nitric acid. It is the seat of a Catholic bishop, and of a Reformed consistory. The place is celebrated for the brightness of its atmosphere, and has been much frequented by invalids, but its salubrity is questioned.—In the 10th century Montpellier was a village of Magnelonne. Increasing as Magnelonne declined, it became a seigniory, which passed in 1294 to the kings of Aragon, and in 1276 became part of the kingdom of Majorca. In 1349 it was ceded to France. Charles V. ceded it in 1365 to Charles the Bad of Navarre, but it returned to the crown under Charles VI. The episcopal see was transferred to Montpellier from Magnelonne about 1538. It suffered much during the religious wars, and was besieged and taken by Louis XIII. in 1622. The edict of Montpellier of Oct. 20, 1622, granted to the Calvinists freedom of worship, but forbade assemblies except of their synods and consistory, and granted them freedom from molestation only in La Rochelle and Montauban.

MONTPENSIER, Antoine Marie Philippe Louis d’Orléans, duke de, a French prince, youngest son of Louis Philippe, born at Neully, July 31, 1824. He was educated at the collège Henri IV., became a lieutenant in the army in 1842, and fought in Algeria, where he was slightly wounded, in 1844. On Oct. 10, 1846, he married the sister of Isabella II. of Spain, an alliance which gave rise to serious complications, owing to the belief that it was intended by Louis Philippe to raise his son to the Spanish throne in view of the anticipated childlessness of Isabella, whose marriage with her cousin Francisco d’Assis was at the same time planned by the French king. He shared his father’s exile in England in 1848, and subsequently resided at Seville. The titles of infante and

MONTPELLIER, capital of the department of Hérault, near the Lz, 27 m. S. W. of Nîmes, 17 m. N. E. of Cette, its port, and 76 m. W. N. W. of Marseille; pop. in 1872, 57,727. The edict of Montpellier of Oct. 20, 1622, granted to the Calvinists freedom of worship, but forbade assemblies except of their synods and consistory, and granted them freedom from molestation only in La Rochelle and Montauban.
of captain general of the Spanish army were conferred upon him in 1859. In 1868 he left Spain for a time, and in 1870 was a candidate for the throne. The rival candidate, Don Enrique de Borbon, brother of Isabella’s husband, having alluded to him in offensive terms, was challenged by Montpensier. They fought March 12, and at the third shot Enrique fell dead. The duke was sentenced by a court martial to one month’s banishment and a fine of $6,000. In 1871 he was exiled to Port Mahon for refusing to take the oath of allegiance to King Amadeus, but as a candidate to the corses he was allowed to return to Madrid. He soon left for Paris, where he still resides. His elder daughter Isabella was married in 1864 to her cousin the count de Paris. In 1874 he lent his celebrated collection of Spanish paintings for exhibition in Boston.

MONTREAL, a city of the Dominion of Canada, in the province of Quebec, the largest in British North America, and the commercial capital of the country, in lat. 45° 31’ N., lon. 73° 35’ W., on the S. E. side of a triangular island of the same name at the confluence of the rivers Ottawa and St. Lawrence. This island, which is about 30 m. long by 10 m. in greatest breadth, is 600 m. from the mouth of the river, 140 m. in direct line S. W. of Quebec, 310 m. N. E. of Toronto, and 355 m. N. of New York. It stands at the head of ship navigation, and at the foot of that great chain of improved inland waters extending from the Lachine canal to the western shores of Lake Superior. In 1861 the population of Montreal was 90,323; in 1871, 107,325 (including 77,980 Roman Catholics and 29,345 Protestants), two thirds being of French origin. It derives its name from Mont Réal, or Mount Royal, rising 750 ft. above the harbor, and covering at the base an area of about 8 sq. m. It is built mostly of a grayish limestone from adjacent quarries, and with its handsome spires and glittering tin roofs, and the picturesque villas that stud its lofty background, is seen to great advantage from the river. The Roman Catholic parish church, Notre Dame, in Place d’Armes, commenced in 1824 and opened in 1829, is built in Gothic style and in the form of a parallelogram. It is 241 ft. long, 135 ft. wide, and seats between 10,000 and 12,000. It has six towers, one at each corner and one in the middle of each flank. The two on the main front rise 213 ft., nearly twice the height of the others. In one of these is a peal of bells, the largest of which weighs upward of 20,000 lbs. The building comprises several aisles and chapel; it is 61 ft. from the foundation to the eaves, and its principal window is 64 by 32 ft. It is at present (1875) the largest religious structure in the Dominion, but it will be surpassed by the Roman Catholic cathedral now in course of erection on the corner of Dorchester and Cemetery streets, after the plan of St. Peter’s at Rome. The English cathedral, in St. Catharine street, is a most perfect specimen of Gothic architecture; it is cruciform, built of rough Montreal stone, with Caen stone facings. Its aisles are 112 ft. long with an aggregate width of 70 ft., and its transept is 100 by 25 ft. Its spire is 224 ft. high. In 1858 the number of churches in the city was 30; it is now 64, viz.: 9 church of England, 21 Roman Catholic, 5 Presbyterian, 5 church of Scotland, 3 Methodist, 4 Wesleyan, 4 Baptist, 2 Jewish, 2 Congregational, 1 French Evangelical, 1 German Protestant, 1 society.
of Friends, 1 New Jerusalem, 1 Christian Advent, 1 Unitarian, and the St. George's Hall congregation. The principal benevolent institutions are the Hôtel-Dieu and St. Patrick's hospitals, attended by the sisters of St. Joseph, the Protestant house of industry and institution for deaf mutes, the infant school, Providence Sacré Cœur, the lying-in and Providence asylums, the dispensary, the eye and ear infirmary, the Protestant and the Catholic Magdalen and orphan asylums, the Catholic benefit society, and the charities under the immediate charge of the sisters of charity. First among the educational establishments is the university of McGill college, which embraces the largest school of medicine in British North America, a faculty of law, normal and model schools, a high school, and a chair of English literature. The collège de Ste. Marie is directed by the Jesuits, and the Montreal college by the Sulpicians, who have charge also of the grand séminaire and the ecclesiastical seminary at St. Sulpice. Besides these are the colleges of Ste. Thérèse and the Assomption. In 1873 there were 9 daily, 2 tri-weekly, 2 semi-weekly, and 17 weekly newspapers published in the city, with 9 monthlies and 3 semi-monthlies. The most important monetary establishments are the Montreal bank, founded in 1818, capital $12,000,000; the Merchants' bank of Canada, $6,000,000; bank of British North America, $4,867,000; City bank, $1,200,000; Banque du Peuple, $1,600,000; and Molson's bank, $1,000,000. Most of these have handsome edifices.—The principal business streets are St. James, McGill, Notre Dame, Commissioner, St. Paul, and the main thoroughfares of St. Lawrence, Quebec, St. Ann, St. Joseph, and St. Antoine suburbs. Most of the leading wholesale dry-goods and hardware houses are in St. Paul street. Of late years some of the narrow and tortuous streets have been widened, but many more remain in their original condition. The Bonsecours market, a fine Doric edifice, contains the city council chamber, corporation offices, and a concert room which seats 4,000 people. A more commodious market is projected, to cost $2,000,000. The court house, built at an expense of $300,000, is a lofty and spacious Ionic building about 120 ft. long. It contains a law library of 6,000 volumes. Back of it is the Champ de Mars, a fine military parade ground. In 1870, on the withdrawal of the British troops from Canada, this and all other imperial property in the city was presented to the Dominion government. In 1860 a crystal palace was opened for the exhibition of the products of the provinces. The merchants' exchange, in St. Sacrament street, is a handsome structure in the semi-Grecian style, with numerous offices and a reading room. The old government house, in Jacques Cartier square, and Nelson's monument, are objects of interest. The geological museum, the university of McGill college with its museum, and the museum of the natural history society, are among the most complete institutions of the kind on the continent. The city is well lighted with gas, which was first used here in November, 1837. Water is obtained from the St. Lawrence, about 14 m. above the Lachine rapids, where the elevation of the river is about 37 ft. above the harbor. It is conducted to the outskirts of the city through an open canal 5 m. long. At the end of this is a wheel house, from which the water is discharged through submerged archways under covered frost-proof passages extending above and below the building. There are two iron wheels, which force the water 20 ft. above the harbor, through a pumping main 22 m. long, into a reservoir with a capacity of 15,000,000 gallons. The works, which cost about $1,800,000, were begun in June, 1853, and water was admitted in September, 1856. The climate of Montreal is subject to great extremes, the summers being hot and the winters severe. The thermometer ranges from 90° above to 30° below zero.—In the beginning of the present century vessels of more than 300 tons could not approach the city. In 1809 the first steam-er, the Accommodation, was launched on the river. About 1854 the Montreal ocean steamship company was formed. Its first vessels were employed in the transport service to the Crimean, and it was not till 1856 that they commenced the regular mail service, which was fortnightly till 1859, when it was made weekly. The harbor has been much improved of late years. Ocean steamships of 8,500 tons can now enter it, and a fine basin has been constructed, capable of accommodating three first-class steamships. The river frontage is nearly 3 m. long, extending from the Victoria bridge to the village of Hochelaga. The wharves are more than a mile long, and of solid masonry, surmounted by a massive stone wall extending from the entrance of the Lachine canal to below the Bonsecours market. The Victoria bridge crosses the St. Lawrence from Point St. Charles at the head of the harbor to St. Lambert on the opposite shore, a distance of about 2 m. It was begun July 20, 1854, and completed in the autumn of 1856. (See Bridge, vol. iii., p. 275.) This bridge belongs to the Grand Trunk railway of Canada, and affords an unbroken line of communication with the United States. The custom house is massive and capacious, and has a fine tower. In 1855 the arrivals from sea were 188 vessels, of 47,394 tons, and the clearances 185, of 27,493 tons. The following tables show the business of the port for four years:

Shipping.
In the exports for 1873 are included 2,764,443 bushels of wheat and 360,108 barrels of flour. The import duties collected in 1870 were $4,128,052. The Lachine canal, 8½ m. long, cuts across the S. point of the island, avoiding Lachine rapids. Since 1846 the waters of this canal and those skirting the river bank inside the upper basin have been turned to good account for manufacturing purposes. The principal manufactures are axes, saws, cordage, printing types, India-rubber shoes, chairs, paper, woolens, cotton bags, steam engines, nails, spikes, joiners’ finishings, and flour. The Grand Trunk railway connects the city with Portland, Me., and the principal places in the Dominion; and the Vermont Central and Montreal and Province Line railways, with their connections, give it direct communication with New York and Boston. Its trade with St. John and Halifax is opened up through the Intercolonial railway.—Montreux is the metropolis see of the church of England in Canada, and the seat of a Roman Catholic bishop. It is governed municipally by a mayor, 9 aldermen, and 18 councillors. The aggregate value of its real estate in 1896 was $235,553,333, and its total revenue from all sources $265,093; in 1873 the value of real estate was $63,561,150, and the total revenue $607,381.—The settlement of Montreal dates from 1535, when it was visited by Jacques Cartier, who named its mountain. The city was founded in 1642, on the site of the Indian village of Hochelaga. It was officially named Ville Marie, and for many years it was indifferently called by that and its present name. In 1758 it was well fortified. In 1760 it surrendered to the British; and it was captured by the Americans, under Gen. Montgomery, in November, 1775, and held until the next summer. In 1779 it contained 1,200 houses, 500 of which were of stone and within the walls, the remainder outside and mostly of wood. Several times it has suffered severely from fire. In 1765 108 houses were burned, and 215 families left destitute. The population was then about 7,000, and one fourth of the city, worth $464,000, was destroyed. In 1768 90 houses, 2 churches, and a large charity school were consumed. In 1849 the parliament buildings and library were burned by a mob, when the government was removed to Toronto. Montreal was the headquarters of the British army in Canada until the final withdrawal of the troops after the consolidation of the provinces into the Dominion.

**MONTREUX**, a commune of Switzerland, in the canton of Vaud and district of Vevey, celebrated for its salubrity and the beauty of its situation. It extends between ridges of the Col de Jaman and the E. extremity of the lake of Geneva, and consists of about 20 villages, with an aggregate population in 1870 of 4,781. The best known village is Clarens. The village of Montreux, near the castle of Chillon, on the lake and 40 m. N. E. of the city of Geneva, is the most frequented in winter, especially by sufferers from diseases of the heart. The mountains on the north protect it against cold and snow, and heavy frosts are unusual. Roses and violets bloom during almost the whole year. The grape cure begins early in September. The rate of mortality is said to be lighter in this locality than in any other part of the world.

**MONTROSE**, a seaport town of Forfarshire, Scotland, 23 m. N. E. of Dundee; pop. of the borough in 1871, 14,548; of the parish, 15,783. It is on the W. side of a sandy peninsula, having the sea on the east, the mouth of the South Esk river, on the south, and a shallow basin 3 m. long and 2 m. wide, which becomes dry at low tide. The harbor is one of the best on the E. coast of Scotland. Its mouth is narrow, but is marked by a lofty beacon on the S. and two lighthouses on the N. E. side, and admits vessels drawing 18 ft. There are quays and dry and wet docks. A chain suspension bridge 432 ft. long, built in 1829, connects the town with the suburb of the Inch across the South Esk. In the High street are statues of Sir Robert Peel and Joseph Hume, who was a native of the place. There are 14 churches, schools for which the town is celebrated, and two lunatic asylums. Between the town and the sea are the Links or downs, celebrated for races and golf matches. Near Montrose are the Montrose pits, a singular hollow in the sea, 30 fathoms deeper than the tract around, where cod are caught in great numbers. There are linen manufactories, employing about 4,000 persons, besides ship yards, iron founderies, and starch manufactories. In 1871 the imports were valued at £277,208, the exports at £21,216; the number of entries was 123, tonnage 31,614; clearances 78, tonnage 16,334. The borough of Montrose received its first charter from David I., early in the 12th century. It was the seat of the first school of Greek in Scotland.

**MONTROSE, James Graham, marquis of,** a Scotch soldier, born at the family estate of Auld Montrose in the autumn of 1612, hanged at Edinburgh, May 21, 1650. At the age of 14, on the death of his father, he became fifth earl of Montrose. He was educated at the university of St. Andrews, and travelled abroad for some years. Being ill received by Charles I., when he visited the court after his return, he joined the Covenanters. His name was put upon the tables of committees for the popular cause, Nov. 15, 1637, and he was prominent in preparing the covenant. On the renewal of the contest in 1649, the earl led the vanguard of the Scotch infantry, but he soon

changed to the royalist side, and was imprisoned in Edinburgh castle by the Covenanters. After his release he remained for some time on his estates. In the spring of 1643 he joined Queen Henrietta Maria in England, but could not induce her to authorize energetic measures in Scotland, and returned home. The Covenanters, vainly endeavored to win him back, and in the summer he again served with the king's army. Early in 1644 he was created marquis of Montrose, and appointed the king's lieutenant general in Scotland. Working on the hatred of many of the highland clans for the Campbells, he raised a force there, and was joined by some Irish infantry. He then commenced a series of brilliant operations, but circumstances prevented them from becoming useful to the king. On Sept. 1 he defeated the covenanting army under Lord Elcho at Tippermuir, and took Perth. On the 12th he destroyed another army in the battle of Aberdeen, and took that town. He ravaged Argyle's country, and defeated the Campbells at Inverlochy, Feb. 2, 1645. Receiving large accessions of force, he stormed Dundee, but abandoned it on the approach of the enemy. On May 8 he encountered Sir John Urrie at Aldearn, and won the most brilliant of his victories. The victory of Alford was won July 2, over Gen. Baillie; whom he again met and conquered at Kil-syth, Aug. 15. But the highlanders formed an unstable force, and Montrose found himself almost without men when he marched to the border. On the morning of Sept. 13 he was surprised at Philhaphig by David Lesley, and his army routed. In July, 1646, he capitulated to Middleton, and on Sept. 3 he sailed for the continent. He was made an Austrian marshal, and authorized to raise regiments for Charles I. After the death of that monarch, Charles II. renewed his commission. Having received some arms and subsidies from Denmark, Sweden, Holstein, and Hamburg he landed in the Orkneys early in 1650, and proceeded thence to Scotland at the head of an ill-organized force of 1,500 men, but was speedily defeated and made prisoner. Sentences of excommunication and forfeiture had been passed upon him by the general assembly in 1644. He was executed with every species of indignity. His head was placed on the Tolbooth, and his limbs were sent to various parts of Scotland. After the restoration Charles II. reversed the sentence of forfeiture, and his remains were buried in state in St. Giles's cathedral.—See "Montrose and the Covenanters," by Mark Napier (2 vols. 8vo, London, 1838), and Grant's "Memoirs of the Marquis of Montrose" (Edinburgh, 1857).

MONTISSERRAT, or Monserrat, one of the smallest of the British West India islands, belonging to the Leeward group, nearly equidistant, or about 30 m., from the islands of Nevis, Antigua, and Guadeloupe; lat. of the N. point, 16° 50' N., lon. 62° 20' W.; area, 47 sq. m.; pop. in 1871, 8,698, of whom scarcely more than 150 were white. About two thirds of the island is mountainous and barren, but the remainder, at the base of the mountain slopes, is fruitful and well watered. The soil is of a light volcanic description. The principal crop is sugar, the export of which in 1870 was 3,382,200 lbs.; in 1871, 3,408,500 lbs.; and in 1872, 2,773,800 lbs. The E. side of the island is mostly uncultivated, covered with high mountains producing cedar and other useful and valuable trees; on the W. side, the land slopes toward the sea. The climate is healthful. In 1874 the value of the imports from the United Kingdom was £27,677, and of the exports to it £29,736. The trade is mainly with other British West India islands. The chief town is Plymouth, on the S. W. coast; it is small, but neat, and the houses are well built of fine gray stone. The government is administered by a president, under the governor-in-chief of the Leeward group, assisted by an executive council and a representative assembly. This island was discovered by Columbus in 1492. In 1623 a party of Irish Roman Catholics from a neighboring island settled on it; and after a French invasion in 1664 it was restored to Britain by the treaty of Breda on July 20, 1667. It was again seized by the French in 1782, and finally made over to England by the treaty of Versailles, Sept. 3, 1783. On March 30, 1872, Montserrat, Antigua, St. Christopher, Nevis, the Virgin Islands, and Dominica were constituted a single colony under one governor-in-chief. Previously the island had a separate government, consisting of a lieutenant governor or president, and a single chamber styled the legislative council.

MONTSERRAT, a mountain of Spain. See Monserrat.

MONTUCLA, Jean Étienne, a French mathematician, born in Lyons, Sept. 5, 1725, died in Versailles, Dec. 18, 1799. After studying at the Jesuits' college of Lyons and the law school of Toulouse, he went to Paris, where he became connected with the Gazette de France. In 1761 he was appointed intendant-secretary at Grenoble, and in 1764 he accompanied the chevalier Turgot as first secretary and astronomer of his colonizing expedition to Cayenne. On returning to France, he became commissioner of the royal buildings, and afterward royal censor. The former office he held for 25 years, till the revolution deprived him of it. He received a pension of 2,400 francs only a few months before his death. He was a member of the institute from its foundation, and in 1755 became a member of the academy of Berlin. He published anonymously Histoire des recherches sur la quadrature du cercle (1754; new ed., 1831), and was the author of numerous other works, the principal of which was Histoire des mathématiques (2 vols., Paris, 1739; completed by Lalande, 1805). ---Montyon, or Montyon, Antoine Jean Baptiste Robert Ange, baron de, a French philanthropist,
born in Paris, Dec. 23 or 26, 1733, died there, Dec. 29, 1820. He was successively intendant of the provinces of Provence, Auvergne, and Amin. As member of the royal council he protested against the dissolution of ancient parliaments decreed by Chancellor Mauppeun, and was deprived of his office. Soon after the accession of Louis XVI. he was appointed councillor of state, became in 1780 chancellor of the count d'Artois (afterward Charles X.), emigrated to England on the breaking out of the revolution, and did not return until the second restoration. He possessed a princely fortune, and devoted the larger portion to philanthropic purposes, founding prizes, assisting his exiled countrymen, and bequeathing to French hospitals over 3,000,000 francs. Every year the French academy distributes two Montyon prizes on a foundation of 10,000 francs each; one to the poor person who has performed the most meritorious deed of virtue, the other to the author of the work most useful for the improvement of public morals. Two others of equal amount are awarded by the academy of sciences: one to him who shall have found during the year some improvement of the medical and surgical art; the other to him who shall have discovered the means of rendering some mechanical art less unhealthy. Montyon published an Éloge du chancelier de l'Hôpital (Paris, 1777); Recherches et considérations sur la population de la France (1779); an essay on the influence of the discovery of America upon Europe, which won a prize at the French academy; Quelle influence ont les diverses espèces d'impôts sur la moralité, l'activité et l'industrie des peuples? (1808); and some other writings.

MONZA, a city of Italy, in Lombardy, on the river Lambro, which divides it into almost equal parts, 9 m. N. N. E. of Milan; pop. about 16,000. Monza was once walled and defended by a castle; the walls are now levelled. The most important building is the cathedral, founded by Queen Theodelinda in 595, and reconstructed in the 13th and 14th centuries. It contains many relics of the Lombard kingdom, of which Monza was the capital. The most celebrated relic is the iron crown which was used for the coronation of the kings of Lombardy and the emperors who subsequently claimed that title. It is mainly of gold, and takes its name from a thin band of iron, said to have been hammered from a nail of the true cross. Napoleon I. was the first who wore it after the emperor Charles V. It was carried off by the Austrians in 1859, but was returned in 1866. The palace of Monza is surrounded by a celebrated park.

MOODY, a S. E. county of Dakota, bordering on Minnesota, recently formed, and not included in the census of 1870; area, 1,228 sq. m. It is intersected by the Big Sioux river, and lies partly on the Plateau of the Coteau des Prairies.

MOOLTAN, or Multan, a city of British India, in the Punjab, 198 m. S. W. of Lahore, with which it is connected by railway, and 3 m. from the left bank of the river Chenab; pop. about 60,000. It is 3 m. in circumference, and has lofty houses but narrow streets, and the numerous bazaars and shops are also narrow. It is overlooked on the north by a fortress, whose walls, which are 40 ft. high on the outside, have 30 towers. In one of the angles of its interior is a large pagoda, supposed to be 1,000 years old, containing the graves of Roorkum Alum and many of his descendants. The local and foreign trade is extensive. The staple manufactures are silks, cottons, shawls, longees, brocades, and tissues. In the vicinity are extensive fruit gardens, and many ruins of tombs and of religious edifices. It is one of the most ancient cities of Hindostan. The English gained possession of it in 1849, after expelling the Sikhs.

MOON, the satellite of the earth, the nearest of the heavenly bodies to us. It is an opaque spheroid 2,159.8 m. in diameter, shining by reflecting the light of the sun. Situated at an average distance of 238,818 m., the moon revolves about the earth in 27-32166 days, this being her mean sidereal revolution. To this motion are due her monthly phases. The course of these, however, is only completed in a lunar month, or synodical revolution, the mean length of which amounts to 29-53059 days. For the phases depend on the moon's position with respect to the sun, which is constantly advancing in the direction of her motion; so that, after completing 360° of her orbit, she has the whole amount of the sun's monthly progress, which is an arc of about 29°, to pass over before she can complete her course of phases.
The former period is sometimes called the sidereal month, the latter the synodic month. When not eclipsed, she always presents to the sun an illuminated hemisphere; her phases depend on the amount of that hemisphere turned toward the earth. If the earth is directly between her and the sun, we see all of it; if she is between us and the sun, we see none of it; if she is midway between these positions, we see half of it. In the first position, she is said to be in opposition; in the second, in conjunction; in the third, in quadrature, or quarter; and her phases, in order, are known familiarly as new, crescent, half-moon, gibbous, and full.—From the constancy of the physical features of the moon's disk, it is evident that she always presents to us the same hemisphere. To do this she must turn upon her axis precisely once while making one revolution in her orbit. This appears to be the general law of the motions of the satellites. But it is not quite accurate to say that the moon constantly presents the same hemisphere to every observer upon the earth. Her axis of rotation being inclined one degree and a half to her orbit, and maintaining the same general direction in space as she moves round the earth, she appears to nod backward and forward in an arc of about 18° in the course of every revolution, exposing to view the regions just beyond her N. and S. poles alternately. Nor is the constancy of the direction of her hither hemisphere is to be referred to the earth's centre, so that the observer, situated upon the extremity of the earth's radius, views her from an elevation of nearly 4,000 m.; and when she is in the horizon it is plain he can look over her elevated edge, as it were. The oscillation thus occasioned is much smaller than either of the others, amounting only to about 2°. These several exposures are called the moon's librations: the first her libration in latitude; the second her libration in longitude; the third her diurnal libration. The absolute maximum librations from the moon's mean position are as follows: libration in latitude, 6° 44'; in longitude, 7° 45'; diurnal, 1° 14'. If the whole surface of the moon be regarded, as equal to 10,000, then instead of seeing only 5,000 parts, as we should do if there were no libration, our range of view extends over 5,802 parts without taking the diurnal libration into account, and over 5,889 parts if diurnal libration be considered. So that only 4,111 parts of the moon out of 10,000 remain absolutely concealed from human ken.—To the casual observer the motions of the moon in different seasons of the year seem exceedingly irregular. She is sometimes seen, at the full, coursing along a circle which passes near the zenith in these latitudes, and sometimes, in the same phase, along an arc low down in the southern sky. It is plain that this is mainly owing to the inclination of the earth's equator to the ecliptic; but there is a large residual effect which is due to the inclination of the moon's orbit to the plane of the ecliptic, amounting to 5° 8', so that during one half of her orbit she is south of the sun's annual path, and during the remaining half north of it. The points where she crosses the ecliptic are known as her nodes; that at which she passes from the southern to the northern side of the line is called her ascending node, the other her descending node. If the ecliptic were a line of light ever conspicuous in the sky, and the moon's path intersecting it also a conspicuous line of light, the place of crossing would be seen to be different every month, being removed further and further to the westward at intervals of about three diameters of the moon. This at least is the average rate of the motion; for the motion is not only not uniform, but is at times reversed. It is known as the retrograde motion of the nodes; the period of completing the whole circuit of the ecliptic is 18,899 years. The orbit of the moon being an ellipse, having the earth at one of its foci, her distance varies in different parts of her monthly course. The nearest point of her orbit is called perigee, the furthest apogee; the two are known as apsides. These points are not fixed, but move forward (on the whole) from west to east, occupying successively every position in the circumference of the ellipse in the course of 8,856 years. These two remarkable motions, viz., of the nodes and

---

**Full Moon, from Photographs taken by Prof. H. Draper, New York.**

572 vol. xi.—51
of the apsides, are due to the disturbing action of the sun.—The moon's surface has no obvious indications of water, nor of an atmosphere. Mr. C. B. Boyle of New York, however, who has long made a special study of the moon, maintains that she has a slight atmosphere, and that she has also water in the shape of numerous small ponds, which for optical reasons are not always visible through the telescope, but have occasionally been noticed by astronomers as bright sparkling points. Schröter (about 1800) claimed to have discovered indications of vegetation on the surface of the moon. These consist of certain traces of a greenish tint which appear and reappear periodically: much as the white spots covering the polar regions of Mars, supposed to be snow and ice, are observed to increase in the winter and waste in the summer of those regions of the planet. As we are able, under the most favorable conditions, to use upon the moon telescopic powers which have the effect of bringing the satellite to within 150 to 120 m. of us, we should doubtless notice any such marked changes on her surface as the passage of the seasons produces, for example, on our own globe. In the most powerful instruments yet constructed the surface of the moon presents a scene of wildest desolation. In every direction are circular caverns or pits, many of enormous size; the floor of one is seen to be strewed with huge blocks. The inner walls are commonly steep, and their depth often frightful, being many thousand feet. They are surrounded by annular ridges, the masses of which would exactly fill the enclosed cavities. In the centre commonly rises a conical mountain. All

this plainly points to a volcanic origin. There are large regions perfectly level, which Sir John Herschel considered to be of a decided alluvial character. There are great rings of mountains enclosing areas of 40 to 120 m. in diameter. From these ranges shoot up stupendous peaks, one to the height of 16,000 ft. Isolated peaks here and there rise abruptly from extended plains to the height of 6,000 to 7,000 ft. These elevations are determined by calculations based on the height of the sun above the horizon of the lunar place under inspection, and the length of the shadows cast. The most favorable time for observing these remarkable features is when the moon is about half full. Beyond the illuminated hemisphere mountain peaks, rising miles above the average level of the surface, are then bathed in sunlight, while the intermediate space is veiled in darkness. Thus the peaks are at such a time seen as silver points detached from the bright crescent; or, if they form a chain stretching toward the rising sun, they may appear as ragged promontories of light jutting far out into the darkness. An admirable chart of the moon has been constructed by the eminent Prussian observers, Beer and Mädler, whose work, Der Mond, must be consulted for a full account of the physical condition of our satellite. They place the height of one mountain at 23,029 ft. This, considered in the relative magnitude of the moon and the earth, is far more stupendous than any known elevation of terrestrial surface. More recently Schmidt of Athens, Greece, has made an elaborate series of observations, extending over the years 1839—'72. The diameter of the chart constructed from these observations is to be six Paris feet, and it is to be published in 25 sections. The application of photography to the moon, though it has not yet resulted in giving maps comparable in accuracy of detail with those by Beer and Mädler, and by Schmidt, has yet given pictures of extreme value and interest. In 1840 Dr. J. W. Draper of New York first succeeded in photographing the moon. With a telescope 5 in. in aperture he obtained pictures on silver plates, and presented them to the lyceum of natural history of New York. Bond of Cambridge, Mass., made photographic pictures 2 in. in diameter with the refractor of the Harvard observatory in 1850. Since then, Secchi in Rome, Bertsch and Arnauld in France, and Phillips, Hartnap, Crookes, De la Rue, and others in England, have made lunar photographs, some of those by De la Rue being admirable. Dr. H. Draper and Mr. Rutherford of New York have taken some of the finest photographic views yet produced. To one of the photographs by Rutherford (taken Feb. 27, 1871) De la Rue ascribes the palm of absolute superiority among all the lunar photographs yet taken.—The mass of the moon is not accurately known, though the most trustworthy determinations agree in placing it at about \(\frac{1}{8}\) part of the mass of the earth. The mass of the moon is intimately associated with her distance and motions. It is best determined from the notation of the earth's axis (see Nutation), and when determined must be added to the earth's mass in calculating the deflecting action of the mutual gravitation of the earth.
and moon, a reduction being made for the sun's perturbing influence. As the actual deflection is known, and can therefore be compared with the result thus theoretically determined, we have a means of testing the various determinations of the moon's distance. Prof. Colbert of Chicago considers that the lunar elements deduced balance each other most satisfactorily if we take the following values: mean equatorial horizontal parallax, 57° 0'67'; mean distance in miles, 238,973; mass of moon to earth's as 1 to 81:98; and thence he deduces: diameter of moon, 2,160:85 m.; volume of moon to earth's as 1 to 49:2; density, earth's as 1, 0:6044; distance of centre of orbit from the earth's centre, 18,121-5 m.; mean distance of centre of gravity of earth and moon from the earth's centre, 2,900:86 m. It may be remarked, however, that the various elements dealt with are not as yet determined so exactly that very much reliance can be placed on the method of testing here indicated. It is to be noted, in passing, that the term lunar parallax as commonly used is applied (not quite correctly, however) in such a way that the earth's radius, instead of being to the distance as cosecant of the parallax, bears to it the ratio, arc : radius. (See Chauvenet's "Astronomy.") The faint apparition of the entire lunar disk at the time of new moon is considered to be due to the reflection of the light received from the earth, whose illuminated hemisphere is then turned toward her.

Moorcroft, William, an English traveller, born in Lancashire about 1780, died at Andkhui, between Bokhara and Cabool, Aug. 27, 1825. He was a veterinary surgeon, and went to India in 1808 as superintendent of the East India company's stud in Bengal. With the view of introducing stallions from the neighborhood of Balkh and Bokhara, and at the same time of establishing commercial intercourse with the trans-Himalayan districts, he travelled beyond the Himalayas in 1812 and 1819, pursuing a route in which no European had preceded him, determining the sources of some of the rivers of Punjab, and visiting Ladakh, Seriling, Cabool, and Bokhara. He purchased several valuable horses, with which he set out on his return in the summer of 1825, but died of fever, under suspicious circumstances. An account of his explorations up to his arrival at Bokhara was published by Prof. H. H. Wilson, "Travels in the Himalayan Provinces of Hindostan and the Punjab, in Ladakh and Kashmir." &c. (London, 1841).

Moore, I. A central county of North Carolina, drained by Deep, Little, and Lumber rivers; area, about 700 sq. m.; pop. in 1870, 12,040, of whom 3,019 were colored. It has a diversified surface, and the soil is fertile near the streams. The Western railroad of North Carolina passes through it. The chief productions in 1870 were 56,528 bushels of wheat, 170,450 of Indian corn, 45,345 of oats, 52,906 of sweet potatoes, 21,761 lbs. of tobacco, 14,209 of wool, 68,072 of butter, and 930 bales of cotton. There were 1,453 horses, 644 mules and asses, 3,616 milch cows, 5,508 other cattle, 10,072 sheep, and 15,125 swine. Capital, Carthage. II. A S. county of middle Tennessee, bounded S. by Elk river; area, about 160 sq. m. It was formed in 1872 from portions of Franklin and Lincoln counties. The surface is diversified and the soil generally fertile. Capital, Lynchburg.

Moore, Alfred, an American scholar, great-grandson of Sir Nathaniel Moore, governor of Carolina in 1705, born in Brunswick co., N. C., May 21, 1755, died at Belfont, N. C., Oct. 15, 1810. At the age of 20 he became captain in a regiment of North Carolina troops, commanded by his uncle Col. James Moore. He subsequently resigned, but when the British seized Wilmington, he raised a troop of volunteers, with whom he rendered great service to the American cause. The war left him penniless, and the general assembly in 1790 made him attorney general; and though he had not yet mastered the first rudiments of law, he soon attained by hard study a foremost rank in his profession, was raised to the bench in 1798, and became associate justice of the supreme court of the United States in 1799. He resigned in 1805.

Moore, I. Benjamin, an American bishop, born in Newtown, L. I., Oct. 5, 1749, died at Greenwich, Conn., Feb. 27, 1816. He graduated at King's (now Columbia) college in 1768, was ordained in England as a minister of the Episcopal church in 1774, became an assistant minister of Trinity church in New York, and succeeded to the rectorship in 1800. On Sept. 11, 1801, he was consecrated bishop of the state of New York, as successor of Bishop Provost. He was also president of Columbia college. In February, 1811, he was attacked by paralysis, which rendered him incapable of further active duty. A collection of Bishop Moore's sermons (2 vols. 8vo, Phila.) was published after his death by his son Clement C. Moore.

Clement Clarke, an American scholar, son of the preceding, born in New York, July 15, 1779, died in Newport, R. I., July 10, 1863. He graduated at Columbia college in 1798, and in December, 1821, was appointed professor of Hebrew and Greek literature, and afterward of oriental and Greek literature, in the Protestant Episcopal seminary in New York. To this institution he gave from his family inheritance the large plot of ground on which it stands. He retired in June, 1850. Dr. Moore published a Hebrew and English lexicon (New York, 1809); a collection of "Poems," the best known of which is the "Visit from St. Nicholas" (1844); and "George Castriot, surnamed Scanderbeg, King of Albania" (1850).

In 1751 he became editor of "The World," in which his own articles appeared under the pseudonym of Adam Fitz Adam. He was the author of two comedies, both of which failed. His tragedy of "The Gamester" (1753) achieved popularity, and is still performed.

MOORE, Henry, an Irish clergyman, born in Dublin in 1751, died in 1843. Under the preaching of the Wesleys he united with the Methodists, was admitted to probation in 1779, labored several years in Ireland, and then became John Wesley's confidential counsellor. He was successful as a revivalist, and founded numerous chapels. After the death of Wesley he was prominent in the discussion as to a church government, advocating the episcopal form. He also defended the itinerant system and the right of Wesleyan ministers to administer the sacraments. He was the last survivor of those whom Wesley had ordained. His principal works are: "Life of the Rev. John Wesley," A History of the Life of Brother the Rev. Charles Wesley, and Memoirs of their Family" (1823), and "Memoir of Mary Fletcher."

MOORE, I. Jacob Bailey, an American author, born in Andover, N. H., Oct. 31, 1797, died at Bellows Falls, Vt., Sept. 1, 1853. In early life he was a printer at Concord, N. H., in partnership with his brother-in-law Isaac Hall, and in 1823 he became a bookseller and publisher. With the assistance of John Farmer he edited and published "Collections, Topographical, Historical, and Biographical, relating principally to New Hampshire" (3 vols., 1822-4). From 1826 to 1829 he edited the "New Hampshire Journal;" he was sheriff of Merrimack county from 1829 to 1834; and in 1839 he edited the New York "Daily Whig." For four years he was a government clerk at Washington; then he became librarian of the New York historical society, and from 1849 to 1853 he was postmaster of San Francisco. His other principal works are: "Annals of the Town of Concord," with a memoir of the Penacook Indians (1824); "Laws of Trade in the United States" (1840); and "Memoirs of American Governors" (1846). The last named work, left incomplete, was designed to embrace all the colonial and provincial governors to the revolution. II. George Henry, an American author, son of the preceding, born in Concord, N. H., April 20, 1823. He went to New York in 1839, and became assistant librarian of the historical society in 1841 and librarian in 1849, office which he still holds (1875). He has published "The History of the New York Naval Vessels" (1860), "History of the United States" (1865); and "History of the United States," with notes by A. W. Walworth, (1867). He has been secretary of legation at Paris in 1869-72. His principal work is "The Rebellion Record" (12 vols. 8vo, 1861-71). He has also edited "Songs and Ballads of the American Revolution" (1855), "Diary of the American Revolution" (2 vols. 8vo, 1860), "Lyrics of Loyalty" and "Rebel Rhymes and Rhapsodies" (1864), and other works.

MOORE, John A. Scottish author, born in Stirling in 1792, and educated at Richmond, near London, Feb. 28, 1802. He graduated at Glasgow, travelled extensively on the continent, chiefly as a private tutor, and afterward practised medicine in London. He wrote "A View of Society and Manners in France, Switzerland, and Germany" (London, 1779), of which several editions and numerous translations were published within ten years; "A View of Society and Manners in Italy" (1781); and "Zelucro," a novel (1789). A uniform edition of his writings, with a memoir, was prepared by Dr. Robert Anderson (1 vols. 8vo, Edinburgh, 1820).

MOORE, Sir John, a British general, eldest son of the preceding, born in Glasgow, Nov. 13, 1761, fell in battle at Corunna, Spain, Jan. 16, 1809. He was educated chiefly on the continent while his father was travelling with the duke of Hamilton. He received a commission in the army in 1776, and served in Minorca and afterward in America till 1783, when his regiment was disbanded. He held a seat in parliament for a short time. In 1787 he was made a major, and in 1790 he became lieutenant colonel of his regiment, which he accompanied in 1793 to Gibraltar. In 1794 he was sent to Corsica, where he distinguished himself and was wounded. He was made brigadier general in 1795, and in 1796 took part in the capture of the island of St. Lucia, West Indies, of which he was made governor. He completely subdued the bands of insurgent negroes, but ill health obliged him to return home in 1797. During the Irish rebellion of 1798 he served on the staff of Sir Ralph Abercromby, and was promoted to the rank of major general. In June, 1799, he accompanied the duke of York on his disastrous expedition to Holland, and was severely wounded. In the Egyptian expedition in 1801 he received a sabre wound in the chest and a bullet in the thigh. On the surrender of Alexandria he returned to England and was knighted. He afterward went to Sicily, and thence, in May, 1808, at the head of about 10,000 men, to Sweden to assist in the defence of that country against Napoleon. He had difficulty with Gustavus Adolphus IV., returned with his troops to England, and was sent to Portugal, where, after the expulsion of the French, he was appointed to the command of the army intended to cooperate with the Spanish forces in the peninsula. He advanced from Lisbon in October, 1808, but discovered that the patriotic zeal with which the French did not exist, and the Spanish forces were defeated at all points. He lingered awhile at Salamanca; but Napoleon at the head of a large force, supported by the whole of the French armies in the peninsula,
was advancing to surround him. His retreat, which began Dec. 11, was through a mountainous and dreary region. The British rear guards joined Astorga Dec. 12, and, having three times checked their pursuers, joined the main army at Lugo, where for two days battle was offered to Soult by Moore, but not accepted. The retreat commenced afresh, and they reached Corunna Jan. 11, 1809, and five days afterward repulsed the enemy in the battle in which their commander fell by a cannon shot. (See CORUNNA.) Soult caused a monument to be erected to his memory, which is also preserved in the well known lines written upon his burial by Charles Wolfe. The British parliament had a monument erected to him in St. Paul's cathedral; and his native city raised a bronze statue to his memory at a cost of £3,000.

MOORE, Nathaniel F., an American scholar, born in Newtown, L.I., Dec. 25, 1782, died near New York, April 27, 1872. He was a nephew of Bishop Benjamin Moore, graduated at Columbia, New York, in 1802, and was admitted to the bar in 1805. He was appointed in 1817 adjunct professor and in 1820 professor of the Greek and Latin languages in Columbia college, retaining his chair till 1835, when he visited Europe. In 1837 he was appointed librarian of the college and in 1842 he succeeded Judge Duer in the presidency, from which he retired in 1849. He published "Ancient Mineralogy" (New York, 1834; new ed., 1859); "Remarks on the Pronunciation of the Greek Language," in reply to a pamphlet by Mr. Pickering; "Lectures on the Greek Language and Literature;" and a "Historical Sketch of Columbia College."

MOORE, Richard Channing, an American bishop, born in New York, Aug. 21, 1767, died in Lynchburg, Va., Nov. 11, 1841. He was educated in Columbia college, and studied medicine, but in July, 1787, was ordained a deacon of the Protestant Episcopal church by Bishop Provost of New York, being the first Episcopal minister who received orders in that state. He was rector of a parish embracing the whole of Staten Island from 1789 to 1809, and afterward of St. Stephen's church, New York. In 1814 he was elected to succeed Bishop Madison as bishop of Virginia, and was till his death also rector of the Monumental church in Richmond. The prosperity of the church in the diocese was greatly increased by his unremitting efforts. He was a prominent leader of the evangelical branch of the church. In 1829 Bishop Meade was appointed his assistant.

MOORE, Thomas, an Irish poet, born in Dublin, May 28, 1779, died at Sloaperton cottage, Devizes, Wiltshire, Feb. 25, 1852. By his father, John Moore, a grocer, he was brought up in the Roman Catholic faith; and at school he acquired a taste for music, recitation, and dramatic performances. As early as 1798 he became a contributor of short poems to the "Anthologia Hibernica," a Dublin magazine. He graduated at Trinity college, Dublin, in 1798, and in 1799 went to London to study law in the Middle Temple, carrying with him a translation of the odes of Anacreon commenced in his school days, which he published by subscription (1800). It proved successful; and gaining the acquaintance of the earl of Moira, he was introduced to some of the fashionable circles of the metropolis. In 1801 he published "The Poetical Works of the late Thomas Little, Esq.," a pseudonyme suggested by his diminutive stature. With much that was polished, tender, and natural, the volume contained many pieces of questionable morality, which were afterward excluded from the collected edition of his poems. In 1803 he was appointed registrar to the admiralty in Bermuda, where he arrived in January, 1804. The office was neither lucrative nor adapted to his tastes; and intrusting his business to a deputy, he returned to England, having first made a rapid tour through a portion of the United States and Canada. His "Odes and Epistles" (1806) presented a series of poetical notes of his progress and comments upon American institutions and literature. This volume was severely handled by Jeffrey in an article in the "Edinburgh Review." Moore challenged the reviewer, and a meeting took place, which was interrupted by the police before a shot had been fired. It was subsequently discovered that one of the pistols had no bullet, and Byron, in his "English Bards and Scotch Reviewers," made a ludicrous allusion to "Little's leadless pistol," for which he was called to account by Moore. A second duel was however avoided, and thenceforth Moore was on terms of warm friendship with both Jeffrey and Byron. In 1811 he married Miss Bessie Dyke, a young actress, and added literature as a profession. Having tried his hand at serious satire in his "Corruption," "Intolerance," and the "Sceptic" (1808-9), he attempted jeux d'esprit and political squibs, writing among others the "Twopenny Post-Bag" (1812), which like most of his similar pieces was in the interest of the whig party. In July, 1813, he was established at Mayfield cottage, near Ashbourne in Derbyshire. Here were written many of the songs adapted to the ancient music of his native country, known as "Irish Melodies." (1807-34). They were commenced at the suggestion of Mr. Power, a music publisher, and were extended to ten series. For the arrangement of the melodies he was indebted to Sir John Stevenson. These songs have enjoyed a popularity beyond that of any similar poems in the English language. He also published two series of "Sacred Melodies" (1816), six series of "National Airs" (1810-28), "Legendary Ballads" (1820), and many miscellaneous pieces, the airs and arrangements for which were prepared by Sir John Stevenson or himself. In the latter part of 1814 Moore agreed to furnish the Messrs. Longman with a poem of the same length as Scott's "Rokeby," for which he was paid £3,000. The idea of writing an oriental ro-
Manoeuvre had occurred to him several years previous, and at the time of making the contract much of the preliminary reading and a portion of the poem were already completed. Two more years of labor produced his "Lalla Rookh," the most elaborate of his works (1817), a series of four eastern stories, connected by a thread of prose. This poem has passed through numberless editions, and has been translated into Persian. After its publication the poet accompanied Rogers to Paris, where he obtained the materials for his "Fudge Family in Paris" (1818), which was succeeded in 1819 by "Tom Crim's Memorial to Congress." About this time, at the request of the marquis of Lansdowne, he took up his residence at Sloperton cottage, near Bowood, Wiltshire, the seat of that nobleman. Having become involved, through his agent in Bermuda, in liabilities amounting to £6,000, in September, 1819, he went to Paris to avoid arrest, declining many offers of assistance. Soon after he accompanied Lord John Russell to Italy, and visited Byron at Venice. His impressions of travel were recorded in his "Rhymes on the Road," published with the "Fables for the Holy Alliance" in 1823. Establishing himself in Paris in 1829, he sent for his family and resumed his literary pursuits. In 1822, after negotiation, the claim against him was reduced to 1,000 guineas, toward the discharge of which the uncle of his agent contributed £300, while the marquis of Lansdowne lent Moore the balance; and he returned to Wiltshire. His "Loves of the Angels" appeared in 1823, the "Life of Sheridan" in 1825, and the "Epicurean," a prose fiction, in 1829. His most important prose work was his "Notices of the Life of Lord Byron" (2 vols. 4to, 1830), founded on the journals and memorandum books of the poet and correspondence furnished by the publisher Murray, and condensed by him. The seven years before Byron had intrusted to Moore an autobiography extending to 1820, to be published after his death, which Moore in 1821 disposed of to Murray for £2,000. The sudden death of Byron in 1824 revealed the existence and projected publication of this manuscript, and Moore was persuaded into an arrangement by which it was repurchased from Murray and burned, on the ground that it contained disclosures affecting the character of many persons, living and dead. The objectionable passages, according to Lord John Russell, did not exceed three or four pages. With such materials as were subsequently procured he compiled a biography, for which he received from Murray £4,870. His remaining works comprise "The Summer Fête" (1831), a poem; "Memoirs of Lord Edward Fitzgerald" (1831); "Travels of an Irish Gentleman in Search of a Religion" (1833); and the "History of Ireland" (4 vols. 12mo, 1835), written for Larner's "Cabinet Cyclopaedia." He wrote little else beyond an occasional trifle in verse for the periodicals, and the prefaces and a few additions to a collected edition of his poetical works, published by the Longmans in 1840-41, in 10 vols. His latter years were clouded by domestic grief, his children having all died before him, and by mental imbecility caused by softening of the brain. In 1835 a literary pension of £300 was conferred upon him. His "Memoirs, Journal, and Correspondence" were sold for £3,000 to the Longmans, who published them in 8 vols. (1832-5), under the editorial supervision of Lord John Russell, in accordance with the testamentary desire of the poet. The journal embraces the period between 1818 and 1847. Moore, Zephaniah Swift, an American clergyman, born in Palmer, Mass., Nov. 20, 1770, died June 30, 1823. He graduated at Dartmouth college in 1793, was principal of the Londonderry academy in 1793-4, entered the ministry, and preached at Leicester from 1798 to 1811, when he was appointed professor of languages in Dartmouth college. He was chosen president of Williams college in 1815, but failing to procure the removal of the institution to the banks of the Connecticut, he resigned in 1821, and was chosen president of Amherst college. Moore, Fowl. See Ptarmigan. Moore (Lat. Mauri; Sp. Moros; Dutch, Moors), the people of Mauritania or Morocco and adjoining parts. The Arabs who conquered Mauritania in the 7th century converted to Mohammedanism the native population, who in Europe were still called Moors, though in their own language they called themselves Berbers, while by the Arabs they were termed Moghrebins, "men of the west." Arabic manners and customs, and in a corrupt form the Arabic language, soon prevailed in the country, the Arab conquerors freely amalgamating with their converts, who far exceeded them in numbers. In 711 an army drawn from this mixed population crossed the straits at Gibraltar, so named from their Arab leader, and began the conquest of the Spanish peninsula. The Spaniards and Portuguese called these invaders Moors because they came from Mauritania, and the term Moors with them soon became synonymous with Mohammedans or Moslems, as the invaders designated themselves. The Spanish writers subsequently applied the term to all the Mohammedans of northern Africa; and when, at the close of the 15th century, the Portuguese reached their way around the cape of Good Hope and encountered the Arabs on the coasts of E. Africa and of S. Asia, they still called them Moors. Even the Turks, who in race, language, and everything but religion, were foreign and alien to both Moors and Arabs, were sometimes loosely spoken of as Moors by the Spanish historians. In 1246 Mohammed ibn Alahmar, king of Granada, became vassal of Ferdinand III. of Castile, and from this time the Moorish rule declined in Spain, until it received its death blow from
Ferdinand the Catholic, who in 1492 raised the cross on the walls of Granada. After this event many of the Moors emigrated to northern Africa, where they were inhospitably received by the Arabs, but found a home in the coast cities. The remnant in Spain, named Moriscoes, were subjected to a bloody persecution by Philip II, and were finally and completely expelled from Spain by Philip III. in 1609. (See Spain.)

MOORSHEDABAD, a town of British India, in Bengal, 124 m. N. of Calcutta; pop. about 150,000, including 90,000 Brahmans and 56,000 Musulmans. It is the most populous town of the district of Moorsabad (area, 2,700 sq. m.; pop. in 1872, 1,355,549), but has been superseded by Berhampore as the capital. The town comprises Moorsabad proper on the E. bank of the Bhagruttee (an arm of the Ganges) and Mahinagar on the W. bank; it extends N. and S. about 8 m., with an average breadth of 4 m. It consists chiefly of mud buildings, but contains a splendid palace of dazzling whiteness, beautifully situated, and completed in 1840; and there is also a native college. The commerce in silk and indigo, the staple products, is considerable, and the situation of the town is the most favorable on the water route between Calcutta and the North-western Provinces; but the port is inaccessible during the spring except for the smallest craft. The defective drainage makes the place very unhealthy. It was once the capital of Bengal, and so prosperous that Clive used to compare it to the city of London; but it has greatly declined. The court of the titular nawab of Bengal, however, still "plays here its farce of mimic state," according to Hunter's "Our Indian Musulmans" (London, 1874).

MOOREK, the native name of a species of struthious bird, discovered in 1857 in the island of New Britain, and named by Mr. John Gould casuarius Bennettii, in honor of Dr. George Bennett of Sydney, N. S. W., who first brought it to the notice of the scientific world. The height of the bird when standing erect is 5 ft., of which the neck is 2 ft.; the color rufous mixed with black on the back, and raven black about the neck and breast; the loose wavy skin of the neck is iridescent, with tints of blue, purple, pink, and green; the feet and legs are large and strong, pale ash-colored, the claw of the inner toe being nearly three times as long as the others; there is a horny plate on the top of the head, resembling pearl covered with black lead; the bill is narrower, longer, and more curved than in the emu, somewhat like that of a rail, with a black leathery cere at the base, and a small tuft of black hair-like feathers behind the plate, continued here and there over the neck; the wings are rudimentary. Living specimens have been exhibited at the London zoological gardens. It seems to form the link between the emu and the cassowary, resembling the former in its bearing and gait; it also resembles the kiwi-kiwi (apteryx) in the style of its motions and attitudes; it is tame and familiar in captivity, and when pleased dances about its place of confinement; it will thrive on boiled potatoes, with occasionally a little meat; it emits a peculiar whistling piping sound, and some louder notes resembling the name given it by the natives; it is shy, difficult to approach, and still more difficult to pursue on account of its speed in running through the thick brush and its extraordinary power of leaping; it has all the inquisitiveness of the domesticated fowls. The eggs are of about the same size and form as those of the common cassowary, having in most cases thick tuberculated shells; they vary from 13 to 14 in. in circumference in the longest diameter, and from 11 to 11½ in. in the widest; the color is pale olive green, with darker olive tubercles; sometimes they are smooth and without spots.—Another struthious bird is the C. australis (Wall), discovered in the Cape York district of Australia in 1854. It is about the same size as the mooruk; the head is without feathers, covered with a bluish skin, and has a bright red protuberance or helmet; the skin of the neck has six or eight round fleshy balls of blue and scarlet; the body is thickly covered with dark brown wiry feathers; the wings are mere rudiments. The flesh was eaten by its captors, and was said to be delicious. It is stronger and heavier than the emu, very wary, and not easily killed except with the rifle.

MOOSE. See Elk.

MOOSEHEAD LAKE, an irregular sheet of water on the borders of Somerset and Piscataquis counties, Me., the largest lake in the state and the source of Kennebec river, about 60 m. long and from 10 to 10½ m. wide. It is situated 1,023 ft. above the level of the sea, in the midst of a wild and as yet mostly uninhabited region, 2 m. S. of the Penobscot and 75 m. N. by E. of Augusta. The densely wooded shores, which in general are but slightly elevated, rise in Spencer mountain, at the head of Spencer bay on the E. shore, to a height of 4,000 ft. Owing
MOOSE WOOD

to the varied nature of the surrounding scenery and to the vast numbers of game, including the deer and caribou, which still frequent the primeval forests. Moosehead lake has for many years possessed a high reputation as a resort for tourists and sportsmen. Steamboats ply daily between Greenville on the S. extremity and Mt. Kineo, a distance of about 20 m.

MOOSE WOOD. See Maple, vol. xi., p. 139.

MOQUIS, a tribe of semi-civilized Indians in Arizona, between lon. 110° and 111° W., and lat. 35° and 36° N., on the Little Colorado and San Juan rivers. They were among the tribes visited in 1540 by Coronado, who apparently left sheep and other domestic animals among them, which they preserved. The Franciscans in time established missions there, but on the general rising in 1680 the Moquis killed or expelled the missionaries. The viceroy of Mexico in 1723 attempted to reduce the Moquis, but failed. In 1748, however, the Franciscan Juan M. Menchero converted a number of them, with whom he founded the pueblo of Gandia. Of late years they have been peaceable, and have suffered much from the attacks of the Apaches and Navajos. They form nine families or clans, the Deer, Sand, Water, Bear, Hare, Prairie Wolf, Rattlesnake, Tobacco, and Red Gras clans, the hereditary chief being of the Deer clan. They are an exclusively agricultural people, raising grain, vegetables, fruit, and cotton. They have some donkeys, sheep, and goats. They live in seven villages situated on bluffs from 200 to 500 ft. high, viz.: Taywah (Tegua), Sechomaive, Juapi (Gualpi), Meschonganave, Shungopave (Xungopavi), and Oreyhe. Their houses are, like those of New Mexico, built in terraced stories, reached by ladders, but inferior to them, though formerly much better than at present. They are of stone laid in mortar, the upper stories are of stone masonry with other poles crossing, covered with rushes; the roofs are of earth. They knit, weave, and spin, making blankets and women's robes, which they trade with other tribes. When they first came within the jurisdiction of the United States they were estimated at about 8,000. Intercourse was for a time cut off by hostile tribes, but in 1852 the Moquis sent curious symbolic presents to the president to open the way to their towns. They were almost destroyed by smallpox in 1855-6, and no help having been given to advance their agriculture, they lost many by famine in 1856-7. On both these occasions they abandoned their villages and scattered among the mountains or emigrated to their allies the Pueblos of New Mexico. Their population in 1873 was pretty accurately fixed at 1,663, showing a great decline. They use no intoxicating drink, and the women are virtuous. The men wear blankets and leggings of dressed skins, the women a woven tunic and a shawl or blanket. Before marriage the latter wear their hair in two rolls like horns at the side of the head, and after marriage in two rolls at the side of the face. The Moquis assimilate in many respects to the people of Zuñi, New Mexico, their ancient allies.

MORA, a N. E. county of New Mexico, bordering on Texas and intersected by the Canadian river and several of its tributaries; area, about 5,000 sq. m.; pop. in 1870, 8,056. The W. part is mountainous. The chief productions in 1870 were 44,115 bushels of wheat, 57,349 of Indian corn, 27,314 of oats, 41,580 lbs. of wool, and 917 tons of hay. There were 673 horses, 808 mules and asses, 3,338 milch cows, 2,928 working oxen, 3,718 other cattle, 30,561 sheep, and 4,827 swine; 4 flour mills, 1 distillery, and 1 woolen mill. Capital, Mora.

MORADABAD, a town of British India, capital of a district of the same name, in the division of Rohilcund in the Northwestern Provinces, on the right bank of the Ramgunga, 100 m. N. E. of Delhi; pop. about 60,000. It is dilapidated, and even the great central thoroughfare has lost its former cleanly appearance. It has a large market place, used as a bazaar, and an extensive commerce in sugar, cotton, wheat, and other articles.

MORALES, Luis de, a Spanish painter, born in Badajoz in 1599, died there in 1686. Either from his constant choice of sacred subjects or (less probably) from the merits of his work, he received the surname of el Divino, the divine. His pictures were nearly all heads, generally of Christ or the Virgin; some authorities believe that there are no instances of his painting the figure at full length. His Ecce Homo and Mater Dolorosa are the best types of his paintings. In spite of his acknowledged ability, the prices he received for his works are said not to have been enough to compensate him for the great labor and time he spent upon them; and he lived in the greatest want until his old age, when he was supported by Philip IV. His house is still at Toledo, Valladolid, Burgos, and Granada.

MORAL PHILOSOPHY, or Ethics (Lat. mos. Gr. ὑθική, manner, practice), the science of duty; the principles which prescribe what ought to take place, and the reasons why it should take place, in human conduct and actions. The ancient Greeks divided philosophy into logic, physics, and ethics: the first treated the universal and necessary forms of thought; the second, so much of the subject matter of thought as pertains to material nature; and the third, the whole nature and activity of free and intelligent beings. More precisely defined, ethics is that division of practical philosophy comprehending the doctrines of the right in human life, and is distinguished from polity and aesthetics, which embrace respectively the doctrines of the expedient and the beautiful or noble. Or it may be defined as natural in distinction from civil jurisprudence, treating of the relations, rights, and duties by which the members of universal society are by the law of nature under obligation toward God, themselves, and each other. Ethics regards mental dispositions; jurisprudence, outward acts. The
former extends to all moral qualities; the latter is limited to the virtue of justice, since no written law can enjoin gratitude or generosity. Moral law is imposed by the conscience; civil law, by the decree of the legislator. Right is what a man may lawfully or morally do. Duty is what he must morally do. Crime is what he lawfully must not do. Vice is what he morally must not do. The law of nature, or the law of God, embracing the law of nations, is sometimes used as comprehending the whole of morality, the whole theory of conduct, and sometimes as containing only those unwritten rules of justice which are enforced by punishment in civilized countries, and at the breach of which it would be generally thought, if there were no government, that men might defend themselves by violence. Positive law, natural law, and moral law have been termed the three ascending degrees in the whole science of duty. The first inquiry in moral science is after an ultimate rule, a supreme principle of life, which shall be of imperative and universal authority, and around which shall be grouped all the motives and maxims of action. From this central principle every ethical system receives its character. These systems may be ranged in two classes, according as the ultimate moral rule is objective or subjective, dependent on something without or within the mind. The most prominent objective theories are those which adopt as the ultimate principle and basis of morality: 1, the authority of the state; 2, the revealed will of God; 3, something inherent in the nature of things; 4, the greatest happiness. Hobbes maintained the first, and Descartes the second. To the third division belong Dr. Samuel Clarke's theory of the fitness of things, Wollaston's of the truth of things, Wayland's of the relations of things, and President Edwards's of the beauty in the union or consent of one mind with the great whole of being, in the love of being in general. To the fourth division belongs the Epicurean theory of personal pleasure, which was made to coexist with virtue by Aristotle, to which Paley gave a more religious aspect by weighing future eternal happiness against present self-renunciation, and which Bentham advanced with reference to public utility and the greatest good of the greatest number. The principal subjective theories find the essence and test of morality in: 1, natural susceptibility to pride, gratified by flattery; 2, an inner reciprocal sympathy; 3, an inner sense, which gives moral distinctions; 4, an immediate intuition. Mandeville defined virtue as the offspring of flattery, begun upon pride, its motives being vanity, and its object praise. Adam Smith urged that the ground of morality was a reflex sympathy, by which the observer changes place in imagination with the actor, and affirms the action to be right or wrong according as it receives or repels his sympathy. Shaftesbury and Hutcheson maintained a distinct and specific moral sense, which immediately apprehends moral distinctions, and is to each man the source of obligation and the measure of virtue. Dr. Brown modified this theory by denying the existence of virtue and vice in the abstract, and claiming that a universal sentiment, by reason of the original conformation of the human mind, approves certain intentions and affections as right, disapproves others as wrong, and is the ultimate source of all moral truth. Friedrich von Schlegel regarded this moral sense or universal sentiment as an inward revelation, which is in us but not of us, which is a divinely awakened awe of the Supreme Being, and which enjoins obedience to every form of God's commandments. Those who claim an immediate intuition of moral truth suppose in the human mind a higher reason for the apprehension of universal and necessary principles. The reason immediately beholds the right, and is of ultimate and absolute authority. Its affirmation, founded on intellectual intuition, is the sufficient sanction of duty. Such, with various modifications, is the theory of Cudworth, Kant, and Coleridge.—Ethics is not, like mathematics or metaphysics, an independent science. It rests upon philosophical or theological principles, only the application or operations of which it deals with. It takes a dynamical and not a statistical view of the elements of life. It presupposes human liberty, the power to employ our mental and physical capacities as we will, and to determine the end toward which they shall be directed; for otherwise the sentiments of duty and of responsibility would be without foundation, would at most be mere phenomena of consciousness, and moral philosophy could be only the natural history of human actions. Its distinctive quality would be lost, destiny taking in it the place of duty. The supremacy of the conscience, however, it be defined, whose mandate is duty, is also presupposed, since a moral nature is requisite to the existence of moral action. Morality, in other respects, implies a supreme law, having reference to a general end, and constituting an ultimate rule of right, the determination of which, and its application to all departments of conduct, are the tasks of moral philosophy. A complete moral system states the supreme good of man, the supreme moral principle which should guide his action, and his particular duties to himself, to mankind, and to God.—Christian ethics is the doctrine of Christian life, embracing so much of dogma and certainties as is not to knowledge but action. Schleiermacher, Rothe, and others have regarded it as identical with dogmatism, on the ground that Christian faith and morals, thought and purpose, knowledge and action, are not separable. It differs from philosophical ethics in its subject, which is not man, but Christians; in its principle, founded on the recognized relation between man and God; in its source, being derived not from the reason, but from the teaching of Christ and the apostles; and in our perception of it, which is not by any analytical process, but by the Christian
MORAL PHILOSOPHY

808

consciousness.—The earliest ethical speculations in Greece appear in the maxims of the gnomic poets. The first attempt to introduce a scientific analysis into the details of practical wisdom was that of Pythagoras, whose moral system was linked with a mysterious symbolism-of numbers. Of oriental origin, the Pythagorean discipline has been likened to philosophy on a tripod; it taught by symbols, spoke in tropes, wrote in verses, and, instead of reasoning, uttered oracles. Its elementary ideas are those of unity and duality, the finite and the infinite, the right and the oblique, to the former of which corresponds good, and to the latter evil. From unity the harmony of numbers is derived, and the sovereign good is the rhythmical order of nature. When the principle of unity predominates in intelligent beings, there is spiritual harmony; and as harmony is not unity, but only an imitative of it, so virtue is not absolute goodness, but only an imperfect representation of it. God is the absolute unity, and is alone wise, and to imitate him as far as possible is the duty of all imperfect beings, who cannot be wise men, but only philosophers or friends of wisdom. The Pythagoreans distinguished the animal soul, whose seat is the heart, and the rational soul, which abides in the brain, and gave to the latter the supremacy. They, therefore, laid stress on self-command and temperance as essential to the vision of truth, and tended to ascetic practices, yet maintained that justice and love were inseparable. They were unsurpassed by any school of antiquity in urging the duties of friendship. The Pythagorean aristocracy resembled an oriental sacerdotal caste, and the Pythagorean political institutions in southern Italy mark the conflict between the genius of the Orient and that of Greece, between theocracy and humanity, the nobility and the people, the servitude of tradition and the liberty of thought. Heraclitus repeated Pythagoras, and Democritus opposed him, founding the sensualist ethical school, and developing the most complete and scientific moral system prior to Socrates, which was, however, only a corollary and result of his atomic physical doctrines. The sovereign good of man, according to him, is not pleasure but happiness, which consists in constant and tranquil content. To be at once temperate, daring, and confident, and, having never done nor wished anything absurd, to trust in fortune, was the whole purport of his ethical maxims. The age of the sophists succeeded. They, however, neither formed a school, nor their doctrines a system. Grammarians, rhetoricians, statesmen, metaphysicians, and moralists, from all the schools of Greek philosophy, their special influence was in inspiring respect for intellectual attainments and performances, and their best service was in habituating the Greek mind to a free examination of all human knowledge. The weapon which they wielded was a rhetorical eloquence, under the sway of which the mythological divinities began to lose their majesty, the ancient traditions which had charmed successive generations ceased to have authority, the institutions of state tended toward equality and toward a foundation of reason instead of experience, and the enthusiasm of Greek culture was transferred from martial and political accomplishments to the arts, letters, and oratory. Their method was powerful to destroy rather than build up, yet the common statement that they were intellectual and moral corruptors is elaborately disputed by Mr. Grote. He regards them as the regular exponents of Greek morality, neither above nor below the standard of the age, maintains that Socrates was not their great opponent but their eminent representative, that they were the authorized teachers, the established clergy of the Greek nation, and that Plato was the dissenter, who attacked them not as a sect but as an order of society. Socrates is usually styled the father of moral philosophy; yet he was rather a sage than a philosopher, and is renowned rather for his wonderful moral consciousness and for his power of exciting the analytical faculties of others than for his positive speculative thought. He affirmed the reality of the distinction between good and evil, that it was founded in nature and not in convention, yet he did not precisely determine wherein it consists. He enjoined the supremacy of duty, yet he gave no objective or subjective definition of virtue. His highest motive was to make reason prevail in human life, public and private, as it prevails in the universe. The elements of his instruction were: a supreme Deity, the principle of order and beauty in nature, and of justice and truth in man; and a series of human virtues, the principal of which were wisdom or a participation in the divine intelligence, justice, which is conformity to universal reason, fortune, which gives courage and strength to endure trouble and resist difficulties, and temperance, which subdues the passions and makes us capable of intellectual delights. He was the first to treat distinctly of ethical science, apart from cosmological and metaphysical speculations, and laid down the principles of law, order, and social security and happiness as the end to which all moral precepts have reference. Like the other moral philosophers of antiquity, he confounded ethics and politics, and was a preacher of virtue in the interest of the state.

—The aim of Socrates was to reform morals, that of his disciple Plato was to explain thought. The latter did not frequent public places to teach the excellence of virtue, but, with a mind whose natural function seemed to be the contemplation of the essence of things, he disdained the shadows of earth for the eternal and divine realities of an ideal world, and developed schemes of thought which caused the fathers of the church to recognize him as one of their precursors. His fundamental ethical principle rests upon the antagonism of the visible and the invisible, the divine and the earthly. Man is an exile upon the earth, to which he is united
by his senses and passions; but by his pure intelligence, his love, by dim reminiscences and regrets, he communes with heaven, which is his true home. He thus by opposite faculties and impulses tends to opposite goals. By yielding to the one he degrades himself, and to some extent perishes. By cherishing the other he resumes and retains his divine excellences. The four cardinal virtues are temperance, courage, wisdom, and love. The first two are relative, the product of earthly imperfection; the second two are real, the remnants of our original perfection. They all have their foundation in wisdom, the fruit of reason, which sees through the material world the world of ideas of which it is a dim copy, and contemplates the supreme beauty of the essential universe. The Platonic morality is therefore speculative; virtue is referred finally to the intellect. A magnificent ideal is presented, the sentiment of love is commanded, and it is assumed that to know the right will be sufficient to practise it. There is no place in his philosophy for that perversity by which the soul sees the better and follows the worse, avoids what it loves and embraces what it hates; a phenomenon, however, which Plato himself has described. The virtue which won his admiration implies a pure intelligence, obedience to which by the heart and will is presupposed. Nor did he precisely define the nature of moral good and evil; his analysis did not reach to the absolute; and he left truth, beauty, and goodness to blend together and lose themselves in their supreme source. God is the principle of moral order, and virtue consists in knowing and imitating him. “Alone among the ancient philosophers,” says St. Augustine, “Plato made happiness consist not in the enjoyment of the body or of the mind, but in the enjoyment of God, as the eye enjoys the light.” The principle of the ideal contained in his philosophy has proved itself imperishable, and has more than once in modern times prompted both ethical and metaphysical speculations to higher standpoint.—The ethics of Aristotle place the sovereign good in happiness, which is inexpressible from virtue, and consists in life and action. The gods themselves are happy only because they act. This theory of activity, which makes virtue to be the best possible disposition of all human functions, was one of the remarkable amendments made by him in the system of his master. An action is right or wrong only when it proceeds from free will and personal responsibility, and its moral desert must be judged by the end which it proposes, that is, by the intention. The Socratic and Platonic mistake of regarding vice as the involuntary product of ignorance is thus corrected. Virtue is a habit, a sort of moral dexterity; single acts cannot constitute it; but the virtuous disposition must be constant, acquired by oft repeated acts, and underlying the whole art of life. But the characteristic ethical statement of Aristotle is that virtue is a mean between two extremes. At one point all the passions are good; below or above that, they violate the order of nature, and are bad. Equally removed from extreme excess and extreme deficiency there lies in all spiritual and physical conditions an intervening state, which is that of virtue. To act when we ought, in the right circumstances, in the proper manner, and for legitimate persons and purposes—that is the juste milieu which characterizes morality. Hence there is always only one way of acting well, while there are thousands in which we may do wrong. He however gives no absolute definition of virtue, as an abstract mean between two abstract extremes, does not determine it as a fixed mathematical point, but makes it relative to the circumstances and disposition of the individual, a centre varying according to the pains and pleasures, desires and hatreds which encircle it. This ingenious theory is derived a posteriori instead of suggested a priori, is an inference and not an instinct, and has perhaps never been applied as a practical criterion of duty. As in metaphysics Aristotle completely severed God from the world, so in ethics he separated the speculative from the practical reason, and gave to morality no foundation in absolute science. His moral scheme was a branch of politics, virtue was a civil quality to be developed only in the state, and his views of man and life were not universal but essentially Greek and republican. To prove that man was something more than a member of society was a task for the future.—This task was fulfilled by the cynicism of Diogenes and the stoicism of Zeno, while the conquests of Alexander may be said to have denationalized the Greek ethics. Diogenes proclaimed himself a citizen of the world, and the government of the universe the only polity worthy of our admiration. Opposed to patriotism, family, and property, the cynic placed virtue in the strength to endure privations and in independence of social relations. Under the banner of inward freedom and power, he verged toward asceticism, meanness, and impudence. The same tendency more strikingly appears in stoicism, the leading feature of which is tyranny over self, a revolt against the senses and passions, contempt of pain, pleasure, death, and of all the accidents of humanity. It was the philosophy of Roman citizenship, lying underneath the inflexibility of discipline and duty. Cleanthes and Epictetus both declared force to be the only virtue. A rigorous adherence to the essential elements, the lowest terms of human nature, a contempt for pleasure as something not designed in the scheme of natural law and inconsistent with its ideal of the freedom and independence of the soul, a striving to shape the individual life according to the rational nature, which is itself in conformity with the rational order of universal nature, an abstract apprehension of virtue as the subject of personal to universal ends, and a consequent moral indifference to exter-
nal good, were the prominent characteristics of the ethical system of the stoics, which was rivalled only by Epicureanism in the amount of its influence on Greek and Roman thought and life. Its moral standpoint was one of abstract subjectivity, its scheme of particular duties was conceived with reference to an ideal of rational freedom, and its motives were all heroic. Stern, haughty, and inflexible, it disregarded the lighter graces both of inward and outward nature in its contemplation of the laws and the energy of the primitive forces of the soul. Stoicism was one of the modes of reaction against the degeneracy of Greek society; Epicureanism, another. Like Aristotle, Epicurus placed the highest good in happiness. The prize of life is the possession of supreme pleasure. All other virtues are but the auxiliaries of prudence or wisdom, which is the architect of our happiness, teaching us, in whatsoever situation we may happen to be placed, to derive from it the utmost advantages. Thus he taught that the man who abandons from the burden of public affairs and from marriage, will observe the laws of his country, acquire means to live with dignity and ease, practise sobriety and moderation, cultivate friendships, and aim after a life without a trouble (arapagia). This serene pleasure he does not allow to be disturbed by fears of death or of the gods; for the gods live in changeless and blessed repose in empty space, undisturbed by any management of human affairs; and death is the end of all feeling, and not an evil to be dreaded, since when death is, we are not. His ethical system does not recognize any positive end of life, and proposes nothing higher than a state of passionless repose; and from the multitude of his disciples during several centuries there proceeded no original thought and no preeminent man. The system itself degenerated, until it became strange that a philosopher who was proverbially blameless and temperate, who nurtured himself on barley bread and water, with which he boasted that he could rival Jupiter in happiness, should have been the founder of Epicureanism. The Horatian nil admirari expresses the melancholy but not the sensuality of its later character. The influence of the Platonic and Aristotelian ethical theories declined; stoicism and Epicureanism remained as rival sects. During the first Christian centuries stoicism predominated in intellectual theories, and philosophers of all schools, poets, historians, and rhetoricians, spoke like Seneca and Epicurus of the sacred love of the world, of the equality of man, of universal law, and a universal republic. Unlike the earlier philosophers, who had founded ethics on the system of the human faculties and passions with reference to their combined operation in the state, the Neo-Platonists gave a theological and mystical character to duty in connection with their doctrines of emanation. The object of life was to rise by processes of asceticism and ecstatic vision from the world of the senses into which we have fallen to our original home in the world of ideas, and the virtues which mark the successive steps in this return are distinguished as physical, political, ethical, purificative, contemplative, and theurgic.—While all antiquity had made the sovereign good consist in escape from pain, either by virtue or by pleasure, Christianity by its celebration of the passion announced the divinity of sorrow. From this time until the rise of modern philosophy ethics cannot be separated from dogmatics. During a thousand years of theological speculations on the problems of life, no system of philosophical ethics was attempted. The characteristic element in Christian virtue is love. If the Christian ideal of perfect charity were realized, ethics and politics would alike be absorbed in a higher science. Prominent as were the ideas of faith, hope, charity, and self-sacrifice in the age of the apostolic and the church fathers, their basis in theory and in their just comparison were speculative, notwithstanding the persuasion that in the reason enlightened by the Word there was given a ground of union between objective revelation and subjective knowledge. Justin Martyr, "the evanglist in the robe of a philosopher," began to apply the forms of ancient ethical philosophy to Christian conceptions of duty, and maintained human freedom by identifying the will and the conscience. Augustine, though aiming to emancipate Christian thought from antique influences, asserted the rationality of Christian morality, since it sprang from the absolute reason of Christ, who was both the central idea in philosophy and the ideal of life. While Augustine and Pelagius were debating free will and sovereign grace, the same question was discussed in a different form by the last of the pagan philosophers, Plotinus and Proclus. The former, in a scheme of universal and absolute determination, suppressed liberty; the latter urged that the essence of personality was liberty, that man was his own controlling demon, and used the terms autokinesia and heterokinesia, corresponding nearly to the autonomy and heteronomy of Kant. The most elaborate attempt to combine the moral ideas of Christianity and those of Alexandrian paganism was made by the writings ascribed to Dionysius the Areopagite, which exerted great influence on later mystical theories. In the middle ages, mysticism, scholasticism, and casuistry successively presided over the doctrines of Christian morality. St. Bernard and St. Victor were the leading representatives of mysticism. The former has been surpassed by no author in his delineations of the worth and power of love. From him proceeded that passionate inspiration, which the monastery of St. Victor perpetuated through the middle ages and which remained the basis of the "Imitation of Christ." The two preeminent Christian sentiments, according to him, are humility and love, both
sprunging from the knowledge of ourselves. A sense of humiliation is the first experience when we duly regard ourselves, and this prepares for intensity of love, which in its highest degree is felt only with reference to God. The great masters of scholastic theological ethics were Peter Lombard, Thomas Aquinas, and Duns Scotus. The aim of all was to harmonize Aristotelianism and Christianity. The first completed the list of the seven cardinal virtues by adding faith, hope, and charity to the ancient series of justice, fortitude, temperance, and wisdom. The second fully developed the mediaval philosophy of virtue. He made the intellect the highest principle, and distinguished universal and special ethics, the former being that of perfect beings in heaven, the latter that of imperfect beings on earth. Duns Scotus opposed the primacy of the will to that of the intellect, and thus introduced a subjective element in place of the objective knowledge to which Aquinas had given prominence. While by the mystical method morality was referred to inner feelings, aspirations, and conflicts, and by the scholastic method it was founded on systems of intellectual principles, the casuistical method assumed prominence, which limited itself to the determination of duty in particular cases (casus conscientiae) in practical life. Numerous works of casuistry, some of them designed for the use of the confessional, were produced from the 13th to the 16th century, the principal of which were the Astesana by a Minorite of Asti, the Angelica by Angelus de Calvasio, the Pianella, also called the Magistrucia, by Bartholomew de Sancta Concordia in Pisa, the Rosella by the Genoese Minorite Trouamala, and the Monaldina by Archbishop Monaldus of Benevento. The Astesana treated in eight books of the divine commandments, of virtues and vices, of covenants and last wills, of the sacraments, of penance and extreme unction, of ordination, of ecclesiastical censures, and of marriage. The tendency of casuistry was to dissipate the essential unity of the Christian life in the technical consideration of a diversity of works. It had begun to decline when it was revived and zealously improved by the order of Jesuits, and became their peculiar ethics. The doctrine of probabilities was developed by them in connection with it. Pascal and others assailed the indefiniteness and ambiguity of casuistical principles. The Medulla of Hermann Busenbaum, which is the basis of the Theologia Moralia of Ligorni, attained the highest reputation as an embodiment of Jesuitical ethics. In the conflicts of the 16th century, when sects, schools, and parties were confounded and transformed, moral philosophy was subordinate to theology and politics. Montaigne, who of all the writers of the time was most distinctive-ly a moralist, pretended to no system. The conciliatory Melanchthon proposed a definition of virtue which included the special features of all the schools and creeds; Suarez maintained the traditions of scholasticism; and Luther, Bruno, and Bacon, as well as the later Descartes, prepared in different ways for the achievements of a new era. One of the relics of mediaval discussion was the foundation of natural law. The disciples of Aquinas made it depend on the nature of things; those of Scotus and Occam, on the authority of God. The former made it essentially a matter of the intellect; the latter, of the will. The former tended to establish morality as independent of the Deity, and to affirm the eternal distinction between right and wrong, even if God did not exist; the latter tended to conceive of the moral law as an arbitrary enactment, to regard nothing as good or bad in itself, and the command of a superior as the only foundation of moral distinctions. The ablest representative of the latter theory in modern philosophy is Hobbes. He denied that anything is naturally right or wrong, affirmed that pleasure and pain are the only objects to be desired or avoided, and limited human selfishness only by the control of an absolute civil power, the necessity of which is proved by experience in order to prevent a state of universal warfare. Morality is thus an artificial and prudential arrangement, dependent on the command of the political chief, without which the only virtues would be force and cunning. On the contrary, Grotius maintained moral distinctions anterior to human convention, and established the law of nature and of nations as a special department in ethical science. The idea of natural law was more precisely determined by Pufendorf, who defined it as the precept of right reason among men mutually social, making a disinterested care for the advantage of society the first duty. It does not extend beyond the limits of this life, is limited to the regulation of external acts, and exists in the nature of things and in the eternal principles of the divine reason. Leibnitz disputed each of these three propositions. The theory of Hobbes was profoundly opposed by Calvinism, which claimed the existence of certain natural laws, independent of experience, and cognizable by right reason, which prompt us to the exercise of moral and social duties. The eternal and immutable distinction of right and wrong in the mind of God and as pure conceptions of the human reason was sustained by Cudworth, and was the occasion of more precise speculations in England as to the mode or faculty by which we perceive the distinction.—The ethical department in Malebranche were the most important produced in France in the latter part of the 17th century. Virtue he defines to be the love of universal order, as it eternally existed in the divine reason, where every created reason contemplates it. Particular duties are but the applications of this love. He substituted for the ancient classification of four cardinal virtues the modern distinction of duties toward God, men, and ourselves. Spinoza, according to his opponents, by denying liberty in man and God, by recognizing only one divine substance and the modes thereof,
made morality impossible, notwithstanding his principal work is entitled Ethica. But by defining clear ideas as those of the reason and vague ideas as those of passion, and establishing it as the object of existence to attain to clear ideas, he succeeded, like most other moralists, in opposing reason to passion. The being of the soul is thought. To increase this, to rise to a greater reality, to preserve and exalt our essential nature, is at once the highest good and the highest virtue. Knowledge is happiness, and is not the reward of virtue, but virtue itself. To follow our desires is the law of practical life, and limitation, deficiency of might, is the only evil. But evil is merely a relative conception of our own, formed by comparison of things with each other; there is no idea of it with God, who is always in harmony with himself, acting according to the laws of his own essence.—In the 18th century moral philosophy rested in England chiefly on theories of disinterested feeling and the moral sense, in France on sensationalism and self-interest; and in Germany the followers of Leibnitz maintained the supremacy of the reason and the doctrine of ideal good. Shaftesbury was the first to employ the term moral sense, which, however, he did not define. Some of his intimations favor the theory of general benevolence proposed by Edward Wollaston’s definition of virtue as conformity to the truth of things, which Dr. Clarke changed to the fitness of things, gives to it an intellectual foundation, since truth and fitness are intellectual conceptions. Morality thus becomes the practice of reason. Hutcheson developed the suggestion of a moral sense by Shaftesbury, and supposed conscience and taste to be separate faculties which immediately introduce us to the objects of aesthetics and ethics. But neither he nor Bishop Butler, after thus determining the subjective condition of virtue, undertook to show the objective distinctive quality common to right actions. Nothing more immediate to the moral emotion and determination is secured by their theory, since neither the moral sense nor the morality of actions is explained by the statement that they correspond to each other. Adam Smith, in referring morality to the principle of sympathy, rendered a service rather to the philosophy of the sympathetic affections than of ethics. Though perhaps no one has ever accepted his statement that moral approval depends first upon sympathy with the motives of the agent, secondly upon sympathy with the gratitude of those who have been benefited by his actions, thirdly upon a perception that his conduct has been agreeable to the general wills by which these two sympathies generally act, and fourthly upon a perception of the utility and beauty apparent in a system of behavior which tends to promote the happiness either of the individual or of society; yet his analysis of the workings of sympathy is admirably conceived and illustrated. It was a part of Hume’s ethical theory that general utility constitutes a uniform ground of moral distinctions. Denying a special moral faculty, he spoke sometimes of sympathy and sometimes of benevolence as the subjective quality which prompts us to be pleased with beneficial actions. Richard Price attempted to revive the intellectual in place of the sentimental theory of virtue, claiming that not only our moral feelings but all our emotions might ultimately be referred to the reason. He regarded right and wrong as simple ideas of the mind.—The maxim of La Rochefoucauld, “Our virtues lose themselves in interest, like rivers in the sea,” describes the ethical theory of the French sensational philosophy. Condillac, the head of this school, regards all intellectual operations, even judgment and volition, as transformed sensations; and Helvétius, applying the theory to morals, held that self-love or interest is the exclusive motor of man, denied disinterested motives, made pleasure the only good, and referred to legislative rewards and punishments as illustrating the whole system of individual action. A superior physical organization alone gives to man his superiority to other animals. La Mettrie maintained an atheistic Epicureanism; and though Condorcet proposed as a goal the perfectibility of mankind in the present state, he looked only to physical improvement, and wished to substitute an empirical education for the ideas and sanctions of religion and morals. But the wave of materialism, and fatalism of the epoch, which saw in the universe only matter and motion, and had pleasure for its single aim and law, were most completely and logically elaborated in D’Holbach’s Système de la nature.—The influence of Leibnitz and Wolf maintained a higher philosophy in Germany, and the latter advanced the ethical principle that we should act only with reference to making ourselves or others more complete and perfect. Moral perfection consists in the harmony of the present with the past and the future, and of ourselves with the material nature of man, whose tendency toward or from the best action is right or wrong. Thus ethics is the science of the possible in life, as philosophy is of the possible in the whole realm of knowledge. A deistomistic and utilitarian school succeeded in the latter half of the 18th century, marked by subjective idealism, which made individual culture and happiness the highest principle and end, and cherished religion on the ground that it was advantageous to earthly pleasure. Basdev, Reimars, and Steinbart were the principal representatives of this tendency, the subjective standpoint of which appears also in numerous confessions and autobiographies, like those of Rousseau.—Kant rescued ethics from the prevalent sentimental and sensational theories. “If,” said he, “happiness, and not the law of inward freedom, be made the fundamental principle, there is an end to moral science.” He defines ethics as the philosophy of the laws of freedom. Freedom is an a priori fact, an element which affirms itself in the activity of the will. The
MORAL PHILOSOPHY

will has the capacity of entire independence or self-determination, bound only by its own autonomy. The pure reason proposes to it a universal law, which we call the moral law, and which is a categorical imperative, requiring an unconditioned obedience. This law is, in Kant's phraseology, the form of human action. Desires, passions, and material motives furnish the contents of action, and their influence constitutes the heteronomy of the will. To exclude principles that are merely of a heteronomous nature, to admit only such motives as may be transformed into universal laws of the reason, so that the autonomy of the will may be inviolate, is the essence of morality. Thus the ethical law of Kant is: "Act only on such a maxim as may also be a universal law." A reverence for the moral law, which he compares to the starry heavens, a severance of the impulses of sense from moral motives, and an estimate of virtue as a triumph over resistance, characterize the Kantian morality. Sanctity is absolute conformity to the moral law, the ideal of moral perfection. Virtue is a constant tendency and progress toward this ideal. The supreme good is the highest happiness joined to the highest virtue. Since these do not correspond in the present state, the practical reason postulates for the attainment of the first the existence of God, and for the attainment of the second the immortality of the soul.—Personal autonomy becomes still more prominent in the philosophy of Fichte. According to him, the most profound and essential truth of our existence is the perpetual striving of the mind to develop itself, to realize its own nature, to bring into actual existence all that lies potentially in its consciousness. This fundamental impulse furnishes the formal principle of ethics, the principle of absolute autonomy, the self-formed aim of being. With it is associated the impulse of nature, which strives not for fulness and freedom, but for enjoyment. Both impulses aim at a unity, and their approximation is an infinite progression of the world," says Fichte, "is the sensitized material of our practical life, the means by which we place before us, as object, the end and aim of our existence." Destiny is the course of the moral determination of the finite rational being. The formula of ethics is therefore: "Always fulfill thy destiny!" this underlies the whole theory of particular duties. The conviction of duty, or conscience, is the condition of the morality of actions. A feeling of truth and certainty is the absolute criterion of the correctness of this conviction, and never deceives, since it exists only when the empirical is in harmony with the absolute Ego. In the later form of Fichte's philosophy, its moral strictness was relieved by religious sentiment, the elements of the Ego and duty being transformed into life and love. His formula, making morality the fulfilment of destiny, is akin to the theory of Aristotle, and was adopted by Jonnfrey, the principal moralist of the French eclectic school. In ethics alone Schelling scarcely departed from the principles of Fichte. In the system of Hegel, jurisprudence, ethics, and politics form the three divisions of the philosophy of mind viewed objectively. The removal of the antagonism between the universal and the particular will constitutes morality. To pursue the rational, or what is in accordance with the universal will, is right; to pursue the irrational is wrong. The three spheres in which moral purpose appears are the family, civil society, and the state. The state is the ethical whole, the highest embodiment of the moral idea, and its will should be supreme over that of the individual. He thus recurs to the ancient notion of merging ethics in politics, gives to morality a foundation of civil absolutism, and regards the rise and fall of states as historical developments of special phases of the reason. Herbert resolves ethics into aesthetics. De Wette adopted Jacobi's principle of feeling as the moral lawyer, and stated the formula: "Live in order to live, and out of pure reverence and love of life:" and Schleiermacher founded a system of ethics in which prominence is given to personal responsibility, and the invisible kingdom of God is made the highest good. Schopenhauer, in consequence of his peculiar psychology, held that progress could be made only by denial of the lower or sensuous instincts, and taught as the fundamental principle of his ethics a form of asceticism. He held indeed to a generous sympathy with our fellow men in all their sufferings and woes, and would encourage even the most heroic exertions in their behalf. But in reference to ourselves he inculcated a pretty severe asceticism. The world, in his estimation, so far from being the best possible, is about as bad as it can be; and while sympathy and the exertions to which it leads tend to alleviate the sufferings of others, asceticism destroys the occasion for sympathy by preventing the evils which excite it. Beneke, however, a contemporary with Schopenhauer, inculcated a system in which morality is based on the feelings. This occasioned the outcry of "Epicurianism," and led him to publish a defence, which however, while varying the statements somewhat, left the general character of the doctrines unchanged. (Die beiden Grundprobleme der Ethik, 1841; 2d ed., Leipsic, 1860.) The more recent German works that embrace the subject of moral philosophy are less metaphysical, being based principally on the results of recent physiological and psychological researches. They attempt, says Lichtthorn, when speaking of the purpose of his own work, Die Erforschung der physiologischen Naturgesetze der menschlichen Geistesthätigkeit (Breslau, 1875), to show that the old metaphysical separation of body and soul, and the assumption that the relationship is merely mechanical, leads to results contrary to experience; and to establish the possibility of reaching a correct solution by combining the great discov-
ery of Du Bois-Reymond on the electro-magnetic nature of sensations and volitions, those of Darwin on organic adaptation and heredity in the animal world, and Haeckel's ever increasing organic perfectibility. The writings of Moleschott, Karl Vogt, Böehmer, and Strauss exhibit a similar tendency when treating ethical questions. Eduard von Hartmann's *Philosophie des Unbewussten* (1869), though more metaphysical, keeps also in unison with the last dicta of experimental science. A further development of this system is Venetianer's *Der Allgeister: Grundzüge des Panpsychismus* (Berlin, 1874).

—Against the doctrines of a moral sense and of disinterested benevolence which had chiefly prevailed in English ethical philosophy from the time of Hutcheson and Butler, and which were zealously defended by Dugald Stewart, a utilitarian tendency was manifested which culminated in Jeremy Bentham. Previous to him Tucker had developed a system akin to the ethical system founded by Hartley's principles of association; and Paley had declared the motive to virtue to be everlasting happiness, and had resolved the art of life into that of rightly settling our habits. Bentham gave to his moral theory the name of "the greatest happiness principle," and represented the practice of virtue as the art of maximizing happiness. All moral action proceeds, according to him, from the calculation of pains and pleasures, estimated by their magnitude and their extent. In the proper balancing of these all morality consists, and virtue and vice are absolutely nothing, merely fictitious entities, when separated from happiness and misery. His aim was to expel from ethical science the word "ought," which was claimed by Mackintosh as the simplest and most universal expression of the moral sense. "The talisman of arrogance, indifference, and ignorance," says he, "is to be found in a single word, an authoritative imposture, which in these pages it will be frequently necessary to unveil. It is the word 'ought.' If the use of the word be admissible at all, it 'ought' to be banished from the vocabulary of morals." Till this is done he proposes to neutralize its effect by the use of another potent word—"why?" Yet Whewell has remarked that it is a mere assumption to prescribe that the answer to this query must be in the language of the utilitarian theory. Bentham urged the formation of general rules of conduct, and strict conformity to them, in order to avoid the temptations of our frailty and passions; and if a reverence for virtuous maxims and precepts thus takes the place in the mind of the utilitarian of the direct application of his principle, there will be little difference between him and the believer in immutable morality, since the practical rules of both will coincide. The latter writings on moral philosophy in England seem to have settled down upon the doctrines: 1, that the aim of morality should be the striving after an ideal standard of human ex-

MORAL PHILOSOPHY

ellence; those most religiously inclined being disposed to take Christ as the ideal standard; others, looking to a model which they have formed for themselves, considering man, his nature and his relations; 2, that there are certain self-evident truths or fundamental axioms in morals as in mathematics, to which everyone who lives in accordance with them must necessarily conform; 3, that the character of all acts is to be determined by reasoning upon their natural tendency, differing in this from Paley's system and the systems of expediency in general, in teaching that the character of acts is to be determined rather by their general features than by the peculiar circumstances of each particular case, and that thus a system of moral philosophy can be built up by reasoning concerning classes of acts, as truthfulness, benevolence, fraud, &c., just as we build up a system of mathematics by reasoning concerning lines, surfaces, solids, &c.; the reasons why, in certain cases, certain self-evident axioms and certain definitions of classes of acts. John Stuart Mill, who acknowledges the influence of both Bentham and Comte, in the latter portion of his work on "Logic" proposes and discusses the inquiry whether ethics may not be reduced to a certain science, and principles be as definitely established in the art of life as the indisputable laws of physics. He develops the subject no further than to state that happiness, in the full meaning of the word, must be the recognized goal of existence and aim of action. Herbert Spencer, without treating moral science in a special work, includes an ethical theory in his general doctrine of evolution. He holds that the science of right conduct determines how and why certain modes of conduct are detrimental and others beneficial. These deductions are to be taken as laws of conduct, and to be conformed to irrespective of a direct estimation of happiness or misery. There have been and still are developing in the race certain fundamental moral intuitions, which are the results of accumulated experiences of utility gradually organized and inherited, which have come to be quite independent of conscious experience; and these moral intuitions will respond to the demonstrations of moral science, and will have their rough conclusions verified by them. Happiness is the end, and the conduct which tends to happiness is right for that reason; yet because the laws of life are fixed, the course of conduct which will secure the greatest happiness will necessarily restrict many individuals. The principles by which individuals are restricted for the sake of the whole are the principles of absolute morality; while the absolutely moral man is not one who conforms to these principles from external coercion or self-coercion, but one who spontaneously is so. Alexander Bain identifies conscience with education under authority. He holds that self-approval and disapproval are transferred, by constant association, from the experience of
reward and punishment for actions to the corresponding disposition to do or avoid those actions. He founds his conclusion on these reasons: 1. That human beings in society are placed under discipline. 2. That when moral discipline is neglected, there is no security for virtuous conduct. 3. That the association of an action with disapprobation and punishment gives rise to a state of mind, in reference to it, which is not distinguishable from moral sentiment.—The Italian school of philosophy of the present century presents the subject of ethics in new phases. Virtue, according to Rosmini, is founded on the idea of possible being. Universal being is the absolute good and the principle of every particular good. Moral good is the absolute good in so far as it is desired by man, since it is desire which first leads him to the idea of perfection, which is elaborated into that of being. The first precept of the moral law, therefore, is to love being as such. But as the moral act must be with reference to the ultimate goal and infinite object of thought, the formula is thus transformed: "Love intelligent beings, not for themselves, but for their supreme end, which is God." Virtue consists in the conformity of intuitive to reflex knowledge, and its essential principle is truth. Obligation rests on the power of rational decision, on what a person knows. Conscience is a speculative judgment on the morality of the practical judgment and on its consequences. Mamiani, also, seeks in ontology the sources of moral order. According to him, "absolute good exists," and a deduction from the idea of a first infinite cause is the fundamental principle of ethics. Virtue is the voluntary cooperation of free and rational beings in the moral order of the universe, in which consists the absolute good, and which converges to God. Deviation, on the contrary, is evil and sin. The moral law in most general terms commands: "Do good." Duty requires the accomplishment of the part assigned to each individual in working out the purpose of society. But beyond this fulfillment, there is a heroic virtue whose object is the greatest possible realization of good, and which consists in the appropriation of individual capacities to the general interests of society. Mamiani maintains, as a matter of history, that right intentions have never resulted in greater evil than good, but that by a preestablished harmony even a false application of a truth must result in some undesigned advantage. The law of progress reigns in the moral as in the material world, and ultimate perfection in an immortal state is the goal of humanity. Gioberti defines virtue to be the knowledge of an absolute law and the conformity of a free will to that law. Law is an idea considered in reference to the will, and an ethical must be founded on a metaphysical system. An ultimate law cannot be considered independently of religion, because it is in fact God himself. The divine will manifested in the moral imperative appears clothed with an absolute right. God as the absolute law reigning over the free human will is the condition of obligation. The ideal formula of Gioberti transferred to the department of ethics becomes: Being, by means of the human will, creates the good; the human will, preferring law to affection, creates virtue; virtue, reconciling affection with law, creates happiness. All these Italian systems of ethics recall the ancient speculations on the subject by referring virtue ultimately to the intellect, making ontological conceptions of being the foundation of responsibility. They also connect virtue closely with religion, and give to it something of an ecclesiastical character.—

The study of moral philosophy by American writers runs back into the last century, when Jonathan Edwards developed his theory of the nature of virtue, which he defined as the love of being in general, including under the term being both God and man, thus finding a philosophical formula for the Scriptural summary of the law. The theory of Edwards was professed by his followers, Samuel Hopkins and Nathanael Emmons, who made virtue to consist in disinterested benevolence, rigidly excluding all self-love. Their theory, however, was held rather as a religious doctrine than as a philosophical opinion. Following the general direction of Edwards, President Dwight and Dr. Taylor held that benevolence is the highest good, blessing both giver and receiver; man being so constituted that he finds his highest happiness in promoting the happiness of others. More recently President Wayland has held that the rule of right is seen in the apprehension of the relations between things; as the relation of parent and child, state and citizen, Creator and creature. President Hickok holds that there is an imperative of reason, which impels us to do that and that only which is due to spiritual excellency. In worthiness of the approbation of our spiritual nature every virtue finds its end. This ultimate right is simple, immutable, and universal. Prof. Haven holds that right is a simple idea incapable of definition, expressing an eternal and immutable distinct inheritance in the nature of things, and not the creation of arbitrary power, whether of man or God. It belongs to all voluntary rational action, arises with the dawn of intelligence, and is universal, and not derived from anything external to the mind itself. Education simply appeals to it. President Hopkins holds that the moral problem is an inquiry after the nature and ground of obligation. It presupposes a moral nature in man, but is not an inquiry as to man's moral powers. The ultimate obligation is that we should choose that which leads to the attainment of the end of our existence, and this is found in love; all questions under theoretical morals may be resolved by an exposition of the law of love, and all questions under practical morals by an exposition of the law of love as a law.

H. Gillett, "The Moral System" (1874).

MORAN. I. Thomas, an American artist, born in Bolton, Lancashire, England, Jan. 12, 1837. His family came to the United States when he was seven years old and settled in Philadelphia. At the age of 16 he was apprenticed to an engraver, but at 19 became a landscape painter, though he never studied under any master. In 1861 he visited England to study the works of Turner and other English artists, returning in 1862. In 1866 he visited England, France, It- aly, and Switzerland. He removed to Newark in 1871, and accompanied an exploring expedition to the Yellowstone river. On his return he painted (1871–2) "The Grand Cañon of the Yellowstone," on a canvas 7 by 12 ft. in size. He afterward visited many parts of the west, including the Yosemite valley and the cañons of the Colorado river, and from studies made in the latter region painted (1873–4) "The Chasm of the Colorado," a picture of the same size. For these two paintings, which were bought by congress, and were the first landscapes ever purchased by the govern- ment, the artist received $20,000. Among his other works are: "Balboa discovering the Pacific" (1860); "Salvator Rosa sketching Banditti" (1860); "Childe Roland" (1861); "Autumn on the Wissahickon" (1863); "The Willds of Lake Superior" (1864); "The Track of the Storm" (1865–6); "The Woods were God's first Temples" (1867); "Hiawatha and the Serpents" (1868); "Dream Land" (1869); and "The Castle of Indolence" (1871). He is also a successful illustrator of books. II. Peter, an American artist, brother of the preceding, born in Bolton, March 4, 1842. When 16 years old he was apprenticed to a lithographic printer, but soon began the study of landscape painting with his brother Thomas. Having become convinced that his best efforts were in animal painting, he went to London in 1864 and spent many months in the study of Landseer's works. Among his principal works are: "A Quarel- some Family," "Domestic Felicity," "Return from the Fair," "Troublesome Models," "The Dawn of Day," "Morning after the Storm," "The Critic," "An Outcast," and "A Rainy Day."—Edward, another brother, is also an artist, devoting himself to marine subjects.

MORAT (Ger. Murten), a town of Switzerland, in the canton and 8 m. N. by W. of the city of Fribourg, on the S. E. shore of the lake of Morat, and on the high road from Bern to Lausanne; pop. in 1870, 2,328. It has a castle and a commercial school, and is memorable for the victory achieved there by the Swiss over Charles the Bold of Burgundy, June 22, 1476. An obelisk was erected on the battle field in 1822. (See Charles the Bold.)—The lake is about 6 m. long, 23 m. broad, and 350 ft. deep. A narrow and flat strip of land separates it from the lake of Neuchâtel, into which it empties through the river Broye.

MORATA, Olympia Fulvia, a learned Italian woman, daughter of the poet Fulvius Peregri- nus Moratus, born in Ferrara in 1526, died in Heidelberg, Oct. 26, 1555. She received a careful and extended classical education, and early in life (according to some authorities in her 16th year) lectured in Ferrara on subjects of classical learning. She married a German phys-ician, Andreas Grunthler, and lived at Schwein- furt, where she became an early convert to Protestantism. In 1553, when the city was captured by Margrave Albrecht of Branden- burg, her library was plundered, and she was compelled to flee to Hamelnburg. Soon after- ward her husband was appointed professor at Heidelberg, and she removed with him to that city. Her works consist of Greek and Latin poems, published in Basel in 1538, and in frequent subsequent editions. Biographies of her were written by Nolten (Frankfort, 1731 and 1775), Kartzschke (Zittau, 1808), and Bonnet (Paris, 1850). The last has been translated into German by Merschmann (Hamburg, 1860).

MORATIN. I. Nicolas Fernandez, a Spanish poet, born in Madrid, July 29, 1737, died there, May 11, 1780. He was a lawyer by profession, but became a professor of law and for some time chancellor of the Spanish theat- re, and, with the aid of a royal injunction, drove the autos sacramentales from the stage. He wrote a comedy called Petimetra (1702), D.iva, a didactic poem (1765), and a narrative poem, Las naves de Hernan Cortés. His best tragedies are Lucrecia, Ormesonda, and Gus- man el Bueno. He also wrote in prose on his- torical subjects. In 1821 his son published a volume of posthumous poems, together with a life and some of his more celebrated lyrics.

II. Leoncio Fernandez de, a Spanish dramatist,
son of the preceding, born in Madrid, March 10, 1760, died in Paris, June 21, 1828. He worked as a jeweller till he was 23 years old. At 18 he obtained the second prize of the academy for his poem La toma de Granada.

In 1780 he published a satirical entitled Leccion poética, and in 1787 he was made secretary to the Spanish embassy at Paris; and he was afterward sent at the public charge to study the drama of Germany, England, Italy, and France. On his return an office in the department of foreign affairs was assigned him. About this time he published a translation of Hamlet, and brought out in the theatre El baron (1803), La mogijata (1804), and El ás de las niñas (1806), the most popular of his plays, performed for 26 nights consecutively, reprinted four times in the same year, and translated into many languages. After many misfortunes he went to Paris in 1827, and died in poverty. Other celebrated works of Moratin are the comedies El viejo y la niña and La comedia de los hermanos y Orígenes del teatro español. He has been called the Spanish Molière. A complete edition of his works has been published.

MORAVIA (Slav. Morava; Ger. Mähren), a margravate and crown land of Austria, situated between lat. 48° 40' and 50° 15' N., and lon. 15° 10' and 18° 28' E., bounded N. and N. E. by Prussian and Austrian Silesia, E. and S. E. by Hungary, S. by Lower Austria, and W. and N. W. by Bohemia; area, 8,985 sq. m.; pop. in 1872, 2,090,975. The country is mostly mountainous, the principal ranges being the Moravian mountains, the Sudetic range with its eastern continuation the Gesenke, and the Carpathians, which respectively separate it from Bohemia, Silesia, and Hungary. The valleys and the southern districts, which are mostly level, are fertile. The principal rivers are the March or Morawa, which rises in the northern corner of the country, flows S. S. E. and S. S. W. through its entire breadth, receiving almost all other waterscourses, and after forming a part of the Hungarian boundary falls into the Danube; the Bečzawa, E. of the March, and the Hanna, Zwittawa, Schwarzwa, Iglawa, and Thaya, W. of it. The Oder, which flows N. E. into Silesia, has its head waters S. of the Gesenke range. The climate is comparatively mild. Moravia yields excellent grains and fruits, hemp, flax, and wine, and vast quantities of timber, iron, coal, marble, alum, vitriol, sulphur, lead, and pipe clay, and some silver. Some of the mines have been known since the 6th century. Gold and silver were formerly extracted, but little attention has been paid to these ores since the 16th century, and the iron and coal mines are not worked to their full extent. Pasturage covers a considerable extent of the country, and large numbers of cattle, sheep, and horses are reared. Woolen, linen, cotton, thread, leather, arms, needles, domestic utensils, porcelain, pottery, glass, paper, beet sugar, and chemical products are manufactured. Railways intersect the country, connecting it with Austria proper, Bohemia, Silesia, and Galicia. The inhabitants are mainly of Slavic origin (about 72 per cent), including Slovaks on the confines of Hungary, Hannaks in the fertile central region watered by the Hanna, and the Czecho-Moravians in the districts adjoining Bohemia. The Germans (26 per cent.) and Jews (2 per cent.) mostly inhabit the towns, the former being most numerous in the regions adjacent to Silesia and Austria. The bulk of the inhabitants are Roman Catholics, the number of the Protestants amounting to 37,000, and that of the Jews to 42,000. Previous to 1848 the latter were subject to the most oppressive obligations and restrictions. The Roman Catholics are under the archbishop of Olmütz and the bishop of Brunn; the Lutherans and Reformed have each one superintendent. Educational institutions of a high grade are numerous, and about 99 per cent. of the children of proper age attend school. The university of Olmütz has been abolished. The provincial diet is composed of the Landeshauptmann, the archbishop of Olmütz, the bishop of Brunn, and 97 deputies. Next to Bohemia and Lower Austria, Moravia has the largest number of manufactories of any Austrian province, the aggregate annual value of the manufactures being estimated at about $74,000,000. In politics and literature the Moravians, mainly according to national lines of division, partake in the movements of the Czechs in Bohemia or of the Germans in Austria. Before the close of the 6th century the country was successively occupied by the Quadi, Rugii, Heruli, and Longobardi, and in the following period by Slavic tribes, who, after the decline of the kingdom of the Avars, founded the empire of Great Moravia, the name being derived from the river Morawa (March). Charlemagne conquered it, and he and his successors exacted tribute and the adoption of Christianity, of which St. Cyril became the great apostle among the Moravians. Swatopluk, who rebelled against the German emperor toward the close of the 9th century, made Moravia a powerful state; but it soon after succumbed to the combined attacks of the Hungarians and Germans. Moravia was now often invaded by Poles, Hungarians, Czechs, and Germans. In the 11th century it was attached to Bohemia, and about the end of the following century constituted a margravate of the empire, though dependent as a fief upon the Bohemian crown. After numerous divisions, it came with Bohemia into the possession of the house of Hapsburg by the death of King Louis II. of Hungary and Bohemia in the battle of Mohács (1526), his crown being inherited by Ferdinand I. of Austria. The Austrian constitution of 1849 made it a separate crown land, as well as Austrian Silesia, which was formerly united with it. (See ARSNA, and BOHEMIA.) In 1866 Moravia was invaded by the Prussians.—See Dudlik, Mährer's allgemeine Geschichte (4 vols., Brunn, 1860-65).
MORAVIANS, United Brethren, or the Unitas Fratrum, a church of evangelical Christians, historically and ecclesiastically distinct from the society of the "United Brethren in Christ," with whom they are often confounded. Their history proper begins with the year 1457; but their preparatory history extends back as far as the 9th century, when Christianity was introduced into Bohemia and Moravia by Cyril and Methodius, who gave the people a Slavonic version of the Bible, and built up a national church. (See Cyril and Methodius.) Hence for several centuries the people of Bohemia and Moravia manifested the spirit of what was afterward Protestantism, holding fast to ecclesiastical principles opposed to the injunctions of the Roman Catholic church, and submitting to the Bible as the only rule of faith and practice. Eventually, however, they were brought under the sway of the papal see. The most celebrated of their reformers was John Huss, who was burned at the stake in 1415. As soon as the news of his death reached his native country, a remnant of his partizans, without any form or power, was formed, and after a time a powerful party arose, called the Hussites, who waged war for several years with great fury against the imperialists. After a time the Hussites separated into two factions: the Calixtines, who insisted principally on the restoration of the cup to the laity in the Lord's supper; and the Taborites, whose aim was a general reformation of the whole church. In 1433 the council of Basel granted the celebrated "compacts" to the Bohemians, by which the most essential of their demands were nominally conceded. The Taborites refused to receive these compacts; whereupon the Calixtines turned their arms against them, and totally defeated them in 1434. The Calixtines now became the national church of Bohemia, and hostilities ceased. But a party among the remnant of the Taborites, dissatisfied with what they regarded as corrupt practices in this church also, withdrew more and more from the communion of the Calixtines, and through the instrumentality of Rokitza or Rokyan, the Calixtine candidate for the archbishopric, who at first favored the movement, received permission from George Poliebrad, then regent and subsequently king of Bohemia, to settle on one of his estates, known as the barony of Litz or Litié. This was in 1456. A considerable number of persons under the leadership of Gregory, a nephew of Rokitza, took up their abode on this estate. In 1457 they organized a religious society, elected 28 elders, and took the name of "Brethren and Sisters of the Law of Christ," which was afterward changed to the simpler one of "Brethren." At a later period the title Unitas Fratrum or "Unity of the Brethren" was adopted. Their pastors were Calixtine priests who entertained evangelical views, and who had joined the society. Such was the beginning of the Moravian church. In 1461, at the instigation of Rokitza, who had become their invertebrate enemy, a fierce persecution burst upon the Brethren, many of whom suffered martyrdom. This persecution only served to increase their number, and in 1467 a synod was held at Lhota, on the estate of Litiz, to effect a more complete organization. After protracted deliberations the Brethren resolved to separate entirely from the national establishment, and to change their society into an independent church. Being anxious to secure the ministry whose validity the Calixtines and Roman Catholics would be compelled to acknowledge, they sought the episcopal succession from a colony of Waldenses, settled on the confines of Bohemia and Austria, who had obtained this succession. The Waldensian bishop Stephen, and his assistants, consecrated three men sent to him by the synod of Lhota to the office of bishop. As soon as these events became known, new persecutions broke out, but the Brethren continued to increase. Toward the close of the 16th century they had more than 400 churches in Moravia and Bohemia, had published several confessions of faith, composed catechisms, and were preparing a catechism and hymn book for publication. In the 16th century they sent several deputations to Luther, but there were differences of opinion between them and him in respect to discipline, on which the Brethren insisted very strongly. They established churches in Poland, and at length the Unitas Fratrum was composed of three provinces, the Bohemian, Moravian, and Polish, each governed by its own bishops, but all confederated as one church, holding general synods in common. In the beginning of the 17th century the Unitas Fratrum became one of the legally acknowledged churches of the land. A remarkable work, completed some time before, was the celebrated Bohemian Bible of Kralitz, translated from the original by a committee of bishops, after a labor of 15 years. In 1621 Ferdinand II. began a series of persecutions directed against all the Protestant denominations in Bohemia and Moravia, and known as the anti-reformation. His plans were successful. Protestantism was totally overthrown in these countries, more than 50,000 of whose inhabitants emigrated. The Brethren's church ceased to exist in Bohemia and Moravia, but continued in Poland about 30 years longer, as a church in exile. This church, too, was destroyed in the war with Sweden (1656), the remnant uniting with the Reformed denomination. In this way the Unitas Fratrum, as a distinct organization, disappeared for 66 years. But John Amos Comenius, the last bishop of the Moravian line, not only published several works by which the history, doctrines, and discipline of the Brethren were preserved, but also provided for the continuance of the episcopate. (See Bohemian Brethren.) Many families of Moravian stock settled in America, many of their fathers. Among these an awakening took place in the first quarter of the 18th cen-
tury, through the instrumentality of a Moravian exile named Christian David. In consequence of this awakening, the desire to live in a Protestant country was felt more and more. Fifty years after the death of Comenius, in the night of May 27, 1722, two families of Moravians escaped from their native country, and reached Berthelsdorf, an estate in Saxony belonging to Count Zinzendorf, who had offered them a refuge. Other Moravians soon joined them, and in five years a colony of 300 persons lived on Count Zinzendorf's estate. They built a town, and called it Herrnhut; introduced the discipline of their fathers, preserved by the publications of Comenius; and in 1735 obtained the episcopal succession of the Unitas Fratrum. Zinzendorf soon became a bishop of the Brethren, and devoted himself entirely to their service. Churches were established in various parts of the continent, in North America, and in Great Britain. In 1748 the British parliament acknowledged the Moravian Brethren as an episcopal church, and passed an act encouraging them to settle in the North American colonies. They devoted themselves to missions among the Indians with great success, one of their most celebrated stations being at Gnadenhütten ("tents of grace") in what is now Tuscarawas co., Ohio, where 100 Moravian Indians were treacherously massacred by whites, March 8, 1782, on a groundless suspicion of having been concerned in certain outrages in Pennsylvania. The numbers of the Brethren, both in America and in Europe, never increased as did those of many other denominations of Christians. This was owing to two causes. First, almost the entire strength of the renewed Moravian church was concentrated on the foreign mission field. Secondly, the fundamental principle underlyi
g the efforts of Zinzendorf and his coadjutors, on behalf of the church at home, was Spener's idea of ecclesiola in ecclesia, little churches within the church, households of faith whose members should be separated as much as possible from the world, and which should constitute retreats where men could hold undisturbed communion with God. This idea, carried out consistently, resulted in the establishment of Moravian settlements, that is, towns founded by the church, where no one who was not a member was permitted to own real estate, although strangers, complying with the rules of the community, were allowed to lease houses. A system so exclusively necessary kept the church numerically small, although it undoubtedly was of great advantage in other respects, and served to foster the missionary zeal which has distinguished the Moravians. During the last 40 years great changes have taken place in the United States in respect to this system, and also in regard to the constitution of the church generally. The last general synod, held at Herrnhut in 1857, remodelled the constitution, and opened the way for a more general development of the resources of the church in the home field.—The Unitas Fratrum now consists of three provinces, the American, continental, and British, which govern themselves in all provincial matters, but are confederated as one church in respect to general principles of doctrine and practice, and the prosecution of the foreign mission work. Each province has a provincial synod, whose executive is an elective board of bishops and elders, styled the "Provincial Elders' Conference," to which the entire management of the church in provincial things, including the appointment of pastors, is intrusted in the interval between two synods. For the general government of the three provinces and the foreign missions, there is a general synod, which meets every 10 or 12 years, and to which each province sends the same number of delegates. The executive board of the general synod is called the "Unity's Elders' Conference," and is the highest judicatory for the whole Unitas Fratrum, when that synod is not in session. In the American province there are two districts, the northern and the southern, each having a synod and a provincial elders' conference. The seat of government for the northern district is at Bethlehem, Northampton co., Pa.; and for the southern, at Salem, Forsyth co., N. C. The Moravian churches in these two districts, without exception, are now like those of other Christian denominations, the exclusive system having been given up entirely. The establishments formerly found in the settlements, and known as brethren's, sisters', and widows' houses, have likewise passed away. In a British province, the seat of government is at Ockbrook, Derbyshire. Only four of the churches of this province are settlements, and even these are gradually undergoing modification. In the continental province, the old system was strictly kept up till quite recently, when several important changes were introduced, which before long will practically do away with the exclusive polity altogether. The governing board, which is the general board for the whole "Unity" (the name by which the Unitas Fratrum is generally known in Moravian phraseology), has its seat at Berthelsdorf, a village on the estate of the same name, in Saxony, about a mile from Herrnhut; it assembles for business in the castle formerly inhabited by Count Zinzendorf, who devoted his entire property to the good of the church. On the continent of Europe a Moravian settlement still has brethren's, sisters', and widows' houses. In a brethren's house unmarried men live together, and engage in various trades and professions, the profits of which go to the church; in a sisters' house unmarried women reside, and have an opportunity of earning a livelihood by different kinds of work; a widows' house is a home for indigent or other widows, where they live comfortably at a very cheap rate. Each house has a spiritual and temporal superintendent, a common refectory and dormitory (except in the case of widows' houses),
and a prayer hall, where religious services are daily held. There is nothing monastic in the regulations by which these establishments are governed. The inmates remain in them entirely at their own option, and are almost invariably such as have no other home. A community of goods never existed at any time in a Moravian church or Moravian institution. During the Indian wars the system was "common housekeeping," as it was called, was introduced; but each person retained his own private property, and when the wars were over and the settlements secure, the system was given up. It continued only for about 20 years.—The Moravians are an evangelical church, in the fullest sense of the term, as it is commonly used in the United States. They have no confession of faith, as such; but the doctrines which they uphold are embodied in a catechism and a special litany, called the Easter morning litany, and used on Easter Sunday only. Such an embodiment of the church, in a doctrinal point of view. Its motto may be said to be that of Augustine: "In essentials unity, in non-essentials liberty, in all things charity." The distinguishing feature of Moravian theology is the prominence given to the person and atonement of Christ. He is regarded as the centre of Christian doctrine, "in whom all the promises of God are yea and amen, and in whom we have the grace of the Son, the love of the Father, and the communion of the Holy Ghost." The Moravian ministry embraces bishops, presbyters, and deacons. Bishops only have the right to ordain. They are usually appointed by lot, in imitation of the mode of appointing the apostle Matthias. The Moravian episcopacy is not diocesan; the bishops are bishops of the whole Unitas Fratrum, have an official seat in the general synod, and can be appointed only by this body, or by its executive board. They do not govern the church in virtue of their office, but only when elected to the governing boards. However, they are almost invariably members of these boards by election. In other respects, their duties relate to the spiritual concerns of the church. The Moravian episcopal succession from 1467 to 1874 embraces 174 bishops. There are 17 bishops in office at present. Of these, 6 reside in Germany, 4 in England, 6 in the United States, and 1 in the West Indies. The ritual of the church is similar to that of the Protestant Episcopal. A litany is used, in several languages, in all the different parts of the Unity; and there are regular forms for infant and adult baptism, the sacrament of the Lord's supper, the rites of confirmation and ordination, burial, and marriage. Love feasts, in imitation of the apostolic agape, are celebrated; and liturgical services, particularly on occasion of church festivals, are held in many churches. The Moravians are distinguished for their church music.—The present numerical strength of the home church is as follows (1875): in the American province there are 75 churches, 8,315 communicants, and 14,737 souls; in the continental, 28 churches, 5,873 communicants, and 7,345 souls; in the British province, 40 churches, 3,249 communicants, and 5,548 souls. The whole number of communicants in the three provinces is 17,436, and of souls 27,630. Although the church is so small, it is engaged in very extensive operations. There are 250 schools and boarding schools in the American province (at Nazareth, Bethlehem, and Lititz, Pa., Hope, Ind., and Salem, N. C.), at which more than 600 pupils are annually educated; 15 in the British province, educating about 400 pupils every year; and 25 in the continental province, with about 1,000 pupils. Nearly all the scholars come from beyond the pale of the church. At Bethlehem, Pa., there is a college, and in connection with it a theological seminary. Similar institutions belong to the continental province. The next enterprise is that of domestic missions. This church, which commenced very recently among the German immigrants. On the continent of Europe the enterprise is extensive, and peculiarly interesting. It is called the work of the Diaspora, from the original Greek of 1 Peter i. 1, and has for its object the evangelization of the state churches, without proselyting their members. Hence societies within these churches are formed and regulated by the missionaries, who hold meetings for prayer and exhortation, and visit from house to house, but never administer the sacraments. There are 120 missionaries, male and female, engaged in this enterprise. It extends over Saxony, Prussia, and other German countries, Switzerland, parts of France, Denmark, Norway, Sweden, and the Russian empire. In the Russian provinces of Livonia and Esthonia the cause prosper very much, there being more than 250 chapels, and more than 60,000 members. The whole number of Diaspora members, as they are called, on the continent, is about 80,000. But the great work which chiefly enganches the energies of the church, and in which all the provinces unite, is that of foreign missions. It was commenced in 1732, when Herrnhiut constituted the only Moravian church, numbering about 400 souls. Since then about 2,300 missionaries, male and female, not counting the native assistants, have labored in this field. Unsuccessful missions were commenced in Lapland, among the Samoyeds, in Algeria, Ceylon, China, Persia, the East Indies, the Caucasus, Guiana, Guinea, among the Calmucks, in Abyssinia, and in Tranquebar. At present the church has missions in Greenland, Labrador, North America (among the Indians), on the Mosquito coast, in the islands of St. Thomas, St. Croix, St. John, Jamaica, Antigua, St. Christopher, Barbados, and Tobago, in Surinam, S. Africa, Thibet, and Australia. There are 383 missionaries in the field, not counting the native assistants; 92 regular stations, not counting the out stations; and 69,322 converts under
MORAWA

religious instruction, of whom 59,843 are in church fellowship, including baptized children, and the rest candidates for admission. The total number of souls connected with the United Fratrum, not counting the Diaspora members, is 99,952. See "The Moravian Manual" (Bethlehem, Pa., 1869).

MORY, Earl of. See Murray.

MORAYSHIRE. See Elginshire.

MORAZAN, Francisco, the last president of the republic of Central America, born in Honduras in 1799, shot in Costa Rica, Sept. 13, 1842. He was secretary general of Honduras in 1824, was soon after elected chief or governor of the state, and distinguished himself both as a statesman and as a military commander. In several contests he led the liberal forces of his own and the adjacent states, with unrivaled success, against the reactionary party, and finally in 1829 drove them from the city of Guatemala, for which the national congress decreed him the title of saviour of the republic. He declined the post of president, but remained commander-in-chief of the forces, and in virtue of special powers delegated to him by the congress, he expelled the archbishop of Guatemala and the monks, suppressed the convents, abolished tithes, and devoted the other property and revenues of the church to education and charity. He inaugurated various schemes of public improvement, in which he was arrested in 1832 by the invasion of the republic from Mexico by a large force under Aree, the expelled president, who was seconded by various local outbreaks of his partisans. These disturbances were promptly suppressed by Morazan, who soon after accepted the presidency. In 1836 the cholera made its appearance with extraordinary fury, and an ignorant population, more particularly the Indians, became much excited, and the clerical party proclaimed that the pestilence was due to the poisoning of the waters by the whites, liberals, and foreigners. The consequence was a general outbreak of the lower orders of the people and the Indians, under the lead of Rafael Carrera. In 1840 Morazan sought refuge in Chili, whence in 1842 he went with some followers to Costa Rica, where he was made governor of the state by acclamation. He at once began to organize an army with a view to the re-establishment of the old federation; but the plan was not popular in Costa Rica, and a revulsion ensued. Morazan and his handful of adherents were surprised, and, after a brilliant struggle, compelled to surrender. Morazan was tried by a drum-head court martial and shot.

MORIBIAN, a maritime department of France, in Brittany, bordering on Côtes-du-Nord, Ille-et-Vilaine, Loire-Inférieure, Finistère, and the bay of Biscay; area, 2,025 sq. m.; pop. in 1872, 400,902. Its name is derived from a gulf on its shore, called Morbihan, or small sea. The coast is indented by numerous bays and harbors. Belle-Isle and several smaller islands off the coast belong to this department. The northern districts are hilly, but the southern are mainly composed of extensive and fertile plains. The principal river is the Vilaine, and the department is traversed by the Blavet and the Brest and Nantes canals. The sardine fishery gives employment to more than 3,000 men. The principal minerals are iron, tin, lead, slate, and salt. There are manufactures of linen, woollens, &c. Ship building is extensively carried on. The common cereals and flax and hemp are raised, and the department is celebrated for its cider. Much attention is paid to rearing bees, and wax and honey are among the principal exports. The inhabitants of Morbihan are Bretons, and speak a dialect somewhat similar to that of the Cornish peasants in England. It is divided into the arrondissements of Lorient, Vannes, Pontivy or Napoléonville, and Ploermel. Capital, Vannes.

MORDANTS (Fr., from Lat. mordere, to bite), materials used in dyeing and calico printing for the purpose of fixing the colors. Their action is in accordance with a twofold attraction for the coloring matter and the material of the fabric, serving as a bond of union. Substances which produce precipitates by acting upon the dyestuff, so that they may be produced within the fibres of the fabric, are also called mordants. In the strictest sense, however, they are not true mordants, but more properly speaking are components of the dyeing material, the mordant being a material that has the property of fixing the dye which has already been produced. It acts by altering the texture of the fibre in such a way as to cause it to retain the particles of the color. The principal mordants are the alumminic, stannic, and ferrie salts, in which the affinity of the base and acid is comparatively weak, so that the precipitated coloring matter may be formed without much difficulty. The action of a mordant generally depends much upon the temperature at which the operation is conducted, as must be apparent from a consideration of the effects of heat upon chemical affinity, the affinity between some substances being much more affected by alterations of temperature than that between others. These reactions are also greatly modified by the nature of the fabric operated upon, and in general can only be well ascertained by experiment. Dyeing, therefore, like nearly all industrial processes, requires for its perfection the combination of theory with practice. (See Calico Printing, and Dyeing.)

MORDAUNT, Charles. See Peterborough, Earl of.

MORDVINS, a people inhabiting eastern Russia. They form a subdivision of the Bulgarie or Volgaic family of the Finnic branch of the Turanian, Urno-Altaic, or Mongolian races, and are related to the Tcheremisses and Tchouvashs. (See Finns.) Their number has been estimated at 400,000, and their territory lies principally between the rivers Oka and Volga in the Rus-
sian governments of Nizhni Novgorod, Tambov, Pensa, Simbirsk, and Saratov, extending also into Samara and Astrakhan. Dialectically they may be subdivided into Mokhla, chiefly dwelling on the banks of the Sura and Mokhla, and Ersas, occupying the shores of the Oka.—See Ahlquist, Moksha-nordische Grammatik (St. Peters burg, 1871).

MORE, Hannah, an English authoress, born in Stapleton, Gloucestershire, Feb. 2, 1745, died in Clifton, Sept. 7, 1833. She was educated at a seminary kept by her sisters in Bristol, in the direction of which she afterward became associated. At the age of 16 she composed a pastoral drama, "The Search after Happiness" (1777). In 1774 appeared her tragedy of "The Inflexible Captive," and in 1775 two legendary poems, "Sir Edred of the Bower" and "The Bleeding Rock." Garrick brought out her tragedy of "Percy" in 1777. "The Fatal Falsehood" was produced in 1779. About this time religious influences induced Miss More to cease writing for the stage. A volume of "Sacred Dramas" (1782), "Florio," a satirical tale (1786), a "Poem on the Slave Trade" and "Thoughts on the Manners of the Great" (1788), and "Religion of the Fashionable World" (1791) were among her next productions. She began at Bath in 1795 a monthly periodical called the "Cheap Repository," consisting of short moral tales written by herself, among which was "The Shepherd of Salisbury Plain." The work attained an enormous circulation. Miss More removed to Cheddard, founded there several schools, and soon extended her charitable efforts for the education of the poor into all the surrounding country. After the appearance of her "Strictures on the Modern System of Female Education" (1799), she was invited to draw up a plan of instruction for the princess Charlotte of Wales, and produced "Hints toward forming the Character of a Young Princess" (1800). "Celebs in Search of a Wife," her most popular work (1801), was composed in 10 years. It was followed by "Practical Piety" (1811), "Christian Morals" (1812), an "Essay on the Character and Writings of St. Paul" (1815), and "Modern Sketches" (1819). In 1825 she removed from Barleywood in Gloucestershire, where she had lived for several years with her sisters, to Clifton. She accumulated by her writings about £30,000, one third of which she bequeathed for charitable purposes. The best edition of her works is in 11 vols. 16mo (London, 1833).—See Memoirs of the Life and Correspondence of Mrs. Hannah More, by William Roberts (4 vols. 8vo, London, 1824; 2 vols. 12mo, New York, 1831). Correspondence of Hannah More with Zachary Macaulay (London, 1860).

MORE, Henry, an English philosopher, born in Grantham, Lincolnshire, Oct. 12, 1614, died in Cambridge, Sept. 1, 1687. He studied at Eton, and in 1631 removed to Christ's college, Cambridge, where he took the degree of bachelor in 1635 and of master in 1639, became a fellow of his college, and passed the remainder of his life in retirement and meditation. The rectory of Ingoldsby was resigned by him in 1642, and he became a prebendary of Clitheroe 1675, but soon resigned. In 1640 he published a philosophical poem, entitled "Psychozoria, or the Life of the Soul." At the request of Lady Conway, a Quakeress, he wrote the Conjectura Cabalistica, the Philosophia Tenonica Censura, and other works. The first of these treatises was an attempt to interpret the book of Genesis into three distinct meanings, the literal, philosophical, and mystical or divinely moral. In 1656 appeared his Enthusiasmus Triumphantus, a discourse on the nature, causes, kinds, and cure of enthusiasm. Among his other publications are: Enchiridium Metaphysicum; "The Mystery of Godliness;" "The Mystery of Iniquity;" a "Discourse on the Immortality of the Soul;" and a treatise entitled "Medela Mundi, or Cure of the World," left unfinished. His principal writings appeared in English (2d ed., 1662; 4th ed., 1712), and a complete edition of his works was published in Latin (1679). His life was written by the Rev. Richard Ward (London, 1710).

MORE, Sir Thomas, an English statesman, born in London in 1490, executed there, July 6, 1535. He was the son of Sir John More, one of the justices of the court of king's bench, was educated in Latin under Nicholas Hart, and in his 15th year was placed in the family of Cardinal Morton, archbishop of Canterbury. The aged cardinal often predicted that "whosoever shall live to see it, this child will prove a marvellous rare man." In 1497 he went to Oxford, where he studied Greek under Grocyn, and formed a lifelong friendship with Erasmus. At the university, or soon after leaving it, More composed the greater part of his English verses, and also wrote Latin epigrams (Basel, 1520), which contain proofs that he always regarded government as dependent on the consent of the people. From Oxford he passed to Nicholas Hart, and in his 15th year was placed in the family of Cardinal Morton, archbishop of Canterbury. The aged cardinal often predicted that "whosoever shall live to see it, this child will prove a marvellous rare man." In 1497 he went to Oxford, where he studied Greek under Grocyn, and formed a lifelong friendship with Erasmus. At the university, or soon after leaving it, More composed the greater part of his English verses, and also wrote Latin epigrams (Basel, 1520), which contain proofs that he always regarded government as dependent on the consent of the people. From Oxford he passed to Nicholas Hart, and in his 15th year was placed in the family of Cardinal Morton, archbishop of Canterbury. The aged cardinal often predicted that "whosoever shall live to see it, this child will prove a marvellous rare man."
at the bar and in parliament was frequently successful against the claims of the crown. His effective opposition to a royal grant, causing Henry VII. to declare that "a beardless boy had disappointed all his purpose," drew a fine and imprisonment upon his father, and he himself had resolved to leave the country at the time of that monarch's death. After the accession of Henry VIII. he was still more prominently employed in public affairs. In 1514 and 1515 he was sent on embassies to the Netherlands with reference to commercial intercourse; after his return he became a privy councillor; in 1521 he was knighted and made treasurer of the exchequer; and at various times he was employed in France to manage the intrigues of Wolsey with Francis I. When parliament assembled in 1523, he was chosen speaker of the house of commons, and displayed his tact and quiet firmness when the house by its silence refused a heavy grant which Cardinal Wolsey had appeared in state to demand. In 1525 he was appointed chancellor of the duchy of Lancaster; in 1527 he accompanied Wolsey on his magnificent embassy to France; and about this time he published several learned, witty, and bitter pamphlets against the reformers. He succeeded to the lord chancellorship in 1529, after the fall of Wolsey, and in this position evaded the demand of the king for an opinion concerning his divorce from Queen Catharine. The charges that he was over-zealous in his official efforts for the suppression of heresy were partially denied in his "Apology," written in 1533. He constantly refused to lend his authority to the king's project of divorce and second marriage; and after holding the great seal for two and a half years, he determined no longer to countenance by his official positions measures which he disapproved, and obtained permission to resign. In his house at Chelsea he lived in retirement, making ready for evil times. Implicated in the alleged imposture of Elizabeth Barton, the nun of Kent, whom he believed to be inspired, he was yet in the investigation treated leniently. When at length in 1534 he was required to swear allegiance to the act of succession for securing the throne to the offspring of Anne Boleyn, he refused, and was committed to the tower for misprision of treason, where he remained more than a year, with permission to receive his relatives and correspond with his friends. A deputation then waited on him to urge his acknowledgment of the royal supremacy, but he declined to answer. The council interrogated him again and again in subsequent interviews; but finally (July 1, 1535) he was brought to the bar of the high commission charged with traitorously imagining and attempting to deprive the king of his title as supreme head of the church. He was condemned, and returned to the tower. On the morning of his execution he dressed in his most elaborate costume, preserved his composure to the last, and, as the fatal stroke was about to fall, signed for a moment's delay while he moved aside his beard, murmuring: "Pity that should be cut; that has not committed treason." There is little information concerning the style of More's oratory. In his prose writings, but a very small part of his vocabulary has become superannuated. His fragmentary "History of Richard III." (1641) is the first example of classical English prose. The work by which he is chiefly known is his Utopia, published in Latin (Louvain, 1516; Basel, 1518), and soon translated into English, French, Dutch, and Italian. It is an account of an imaginary commonwealth in the island of Utopia, feigned to have been discovered by a companion of Amerigo Vespucci, from whom More learns the tale. Society there is represented as free from indolence and avarice, luxury and want, oppression and intolerance; and the ideas that pervade the account are in advance of the age of the author. The best English translation is by Bishop Burnet. A collection of More's Latin works was published at Louvain in 1556, and of his English works at London in 1557. There are biographies by his son-in-law Roper (1626), Hoddesdon (1862), his great-grandson Thomas More (1726), and Sir James Mackintosh ("Cabinet Cyclopaedia," 1881). MORE. See Peloponnese.

MOREAU, Jean Victor, a French general, born at Morlaix, Aug. 11, 1763, died at Laun, Bohemia, Sept. 2, 1813. He studied law at Rennes, and in 1787 was made provost of the school. He supported the parliament of Brittany in its opposition to the crown, but afterward exerted his influence against it, and became the leader of the revolutionary party at Rennes. In 1792, at the head of a battalion of volunteers, he joined the army of the north, was made a brigadier general in 1793, and general of division in 1794. Commanding the right wing of the army under Pichegru, he had an important share in the conquest of Holland. In the campaign of 1796 he was commander-in-chief of the army of the Rhine and Moselle, defeated the Austrians under the archduke Charles at Neresheim, Aug. 11, and penetrated to the centre of Bavaria; but hearing of Jourdan's defeat at Würzburg, and being aware that the archduke with all the Austrian forces in Germany was falling upon him, he made a masterly retreat in the face of two powerful armies, so that on arriving in Alsace after an orderly march of 26 days, his own force was unimpaired, and he had 18 guns and 2 standards taken from the enemy, and nearly 7,000 prisoners. In the following year he recrossed the Rhine and took the fortress of Kehl, but was stopped by the news of the preliminaries of Leoben. He was suspected on account of his friendship for Pichegru, and for 18 months remained out of service. The directorial government recalled him in the day of danger. Sent to northern Italy under Schérer, who left him in command of the French troops when
everything seemed to be lost, he was defeated by Suvaroff at Cassano, April 27, 1799, and executed a retreat from the banks of the Adda first to Turin, and then to Genoa, which, though less famous, is perhaps more admirable than that of 1796. He and Macdonald were superseded by Joubert, under whom Moreau consented to serve. Joubert having been killed at Lodi, Moreau again became chief of the French army. He had in the mean while been appointed commander of the army on the Rhine. Passing through Paris, he became acquainted with Bonaparte, and assisted him on the 19th Brumaire by watching over the two reluctant directors who were kept prisoners in the Luxembourg palace. While Bonaparte was executing the campaign which ended with the victory of Marengo, Moreau, who had crossed the Rhine, April 25, 1800, had several successful contests with the Austrians, drove Gen. Kray across the Danube, won the decisive battle of Hochstädt, advanced as far as Munich, and on July 13 signed the armistice of Parsdorf. Austria showing a disinclination to a definite arrangement, a winter campaign was required. Moreau, with 100,000 men, received orders to cross the Inn and march on Vienna. On Dec. 3 he met the Austrians under the archduke John at Hohenlinden, where he won a brilliant victory. He then rapidly crossed the Inn, the Salza, and the Traun, defeated the archduke Charles at Lamberch, occupied Linz on the Danube and Steyer on the Enns, and was within two days' march of Vienna when the emperor consented to the terms proposed by the first consul, and signed the treaty of Lunéville, Feb. 9, 1801. After his return to Paris, Moreau married; and yielding to the influence of his wife and mother-in-law, who persuaded him that he was not treated as he desired to be, he gave free expression to his discontent, and was privy to, if not deeply concerned in, the conspiracy of Georges Cadoudal and Pichegru in 1804. For this he was sentenced by a court martial to two years' imprisonment, which Bonaparte commuted to exile. Moreau came to the United States, bought an estate at Morrisville, Pa., on the Delaware river, opposite Trenton, N. J., and engaged in agricultural pursuits. At the end of nine years Alexander I. of Russia invited him to return to Europe, and gave him a flattering welcome. He was induced by the czar to devise a plan for the invasion of France. He became a bosom companion of Alexander, was near him at the battle of Dresden, Aug. 27, 1813, and was advising upon a certain manoeuvre on a hill near Bäcknitz, when a cannon ball from Napoleon's guard broke both his legs. He was carried on the retreat to Bohemia, and died five days later. His remains were interred in St. Petersburg. A monument was dedicated to Moreau in Paris in 1819.—See Vie politique, militaire et privée du général Moreau, by A. de Beauchamp (8vo, Paris, 1814). The best account of his career is found in Thiers's Histoire de la révolution française and Histoire du consulat et de l'empire.
Morelia

charred soil, it was the custom of the peasants to encourage their growth by setting fire to the woods, a practice now prohibited by law. There are several other species of morechella in this country and Europe, all of which, according to some authors, are edible, while Berkeley says that M. semiilbera is of doubtful reputation. There is no record in the principal European horticultural works of any attempts to cultivate this fungus, but it would not be difficult to imitate the conditions under which it grows naturally.

Morelia, an inland city of Mexico, capital of the state of Michoacan and of a district of its own name, 125 m. W. by N. of Mexico; pop. officially estimated in 1869 at 30,000. The city stands upon a rocky hill 6,438 ft. above the sea; its streets are wide and cross each other at right angles, but are mostly disfigured by open sewers. On one side of the Plaza de los Mártires, the largest square, stands the cathedral, and the other side is flanked by extensive arcades, the principal business centre. The construction of the houses is remarkably substantial, but few of them are of more than two stories. The cathedral has two towers about 200 ft. high. The government palace has a handsome exterior. The San Nicolas college, first built in the 16th century, and reconstructed in 1868, in the renaissance style, is one of the finest edifices in the republic. The numerous convents and nunnery were suppressed in 1859, and the buildings are for the most part in ruins. Water is supplied by an aqueduct, constructed in 1788, 3 m. long, with vast and lofty arches, and of imposing aspect. The bull ring is one of the best and most spacious in Mexico. There are two churches or houses of refuge, one for each sex, a hospital, a fine prison, two or three barracks, and two cemeteries. Besides the college above mentioned, including departments of law, medicine, pharmacy, and agriculture, there is a considerable number of schools of various grades. The manufacturing industry is limited to cotton and woollen factories, of which there are two factories, one having 68 looms and employing 200 hands; and guayabate, a delicate fruit preserve, extensively exported to Mexico.

The city was founded in 1541, and received the name of Valladolid, which in 1828 was changed to that of Morelia, in honor of the patriot José María Morelos, who as well as Iturbide was a native of the place. In spite of a somewhat insalubrious climate, periodical inundations, and occasional earthquakes, Morelia has rapidly increased in extent and importance; in 1856 it had only 36 streets, and now has 99. It was made a bishopric in 1803.

Morella, Count de. See Carrera, Ramon.

Morelos, an inland state of Mexico, bounded by the state and the federal district of Mexico, Puebla, and Guerrero; area, 1,887 sq. m.; pop. in 1868, 121,098; in 1878, according to the annual report of the ministry of public works, 147,089. This state, which was formerly included in that of Mexico, forms a part of the S. E. slope of the central table land, and has a mean elevation of about 4,500 ft. above the sea. It is a mountainous, and the volcano of Popocatepetl, one of the highest points, if not the culminating point, of North America, is on the N. E. boundary; but the highest peaks are separated by plains of remarkable fertility. Almost the whole country is of volcanic formation. The cave of Cacahuamilpa, near the village of the same name, is reported one of the most curious in the world; the entrance is formed by an arch 75 ft. high and 150 wide; in the interior are vast natural divisions or compartments called alone, where snow-white stalactites and stalagnites abound, resembling obelisks, palms, &c. Numerous streams water the plains, but the Cuernavaca and Cuantla, tributaries of the Amacuasque, are the only considerable rivers. The climate, mild in the north, is extremely hot and insalubrious in the south; malignant fevers and endemic dysentery are the prevailing maladies. The staple products are the sugar cane and several varieties of exotic fruits, immense gardens being laid out in various parts of the state for their cultivation. There were 22 silver mines in operation in 1873, and gold, quicksilver, cinabrar, lead, chalk, and kaolin are produced. The principal industries are the manufacture of sugar, molasses, and rum of superior quality. The sugar manufactured in 1873 amounted to 20,475,200 lbs., and the molasses to 3,623,211 gallons. There were in the state 186 public schools, 32 of which were for females, with an aggregate attendance of 7,271, exclusive of 36 enrolled in the state literary institute at Cuernavaca. Morelos is divided into five districts, and the chief towns are Cuernavaca, the capital, Cuautla de Morelos, Yaucatepec, Jojacatepe, and Tete-Cola.

Morelos, or Montemorelos, a city of Mexico, capital of a district of the same name, in the state of Nuevo Leon, 70 m. S. E. of Monterey; pop. about 9,000. The town is 2,000 ft. above the sea. The old portion is ruinous, but the modern part has wide and regular streets, substantial buildings, and courtyards filled with trees and flowers. Streams of pure water flow through the streets. There are several churches, three public schools, and manufactories of sugar, rum, agricultural implements, hardware, silver, and hats. The original name of the city was San Mateo del Pilon.

Morelos, José Maria, a Mexican revolutionist, born in 1780, shot in the city of Mexico, Dec. 22, 1815. He was curate of Nuecuptaro in Valladolid, and in October, 1810, joined the insurgent chief Hidalgo against the Spaniards, receiving a commission to act as captain general of the provinces on the S. W. coast. He set out with five negroes to conquer Acaupulo, which was strongly garrisoned. On his march he was joined by about 1,000 men, chiefly negro slaves, with whom under cover
MORETO of night he surprised and signally defeated the Spaniards, Jan. 25, 1811. His army at length acquired discipline, and he encountered the Spanish army at Cuautla Amilpas, Feb. 19, 1812, and defeated it after a hard-fought battle, in which the royalists lost 500 men. A second army was sent against him, and for several weeks he was besieged in Cuautla, from which he skilfully withdrew his troops May 2, in the face of a greatly superior force. Subsequently he won several victories, captured Orizaba, Tehuantepec, and Oaxaca, and at length compelled Acapulco to surrender, Aug. 30, 1813. In December of the same year he marched against Valladolid, but was defeated there by Iturbide with great loss. From this time he suffered a succession of defeats, till on Nov. 16, 1815, he was taken prisoner after a gallant resistance against an overwhelming force, and was carried to Mexico, tried, and executed. He died with the utmost composure.

MORETO, Agustin, a Spanish dramatist, born about 1600, died in Toledo, Oct. 23, 1669. He was prominent as a writer for the stage until the last 12 years of his life, which he passed as rector of the hospital of el refugio of Toledo. He was a friend and imitator of Lope de Vega and Calderon. His works comprise a few religious and heroic plays, and some serious dramas. His most popular comedy, Desden con el desden ("Disdain met with Disdain"), is reckoned among the four classic productions of the Spanish drama, and was adapted for the French stage by Molière (La princesse d'Elide), for the Italian by Carlo Gozzi (La principessa filosofa, o il Contraveleno), and for the German by Joseph Schrevgogel (West), under the title of Donna Diana. The most nearly complete edition of his comedies was issued between 1676 and 1703.

MORETO, II. See BONVICINO.

MORFIT, Campbell, an American chemist, born in Herculaneum, Mo., in 1820. He studied at Columbia college, Washington, D. C., and subsequently devoted himself to the study of chemistry in the laboratory of Prof. James C. Booth of Philadelphia. He then engaged in the manufacture of commercial chemicals. In 1848 he became co-editor with Prof. Booth of the "Encyclopaedia of Chemistry." He published numerous scientific papers, and also wrote a report to the United States ordnance department on gun metal. For the investigations to which this latter refers he established a laboratory at the Pikesville arsenal, Md., and he originated the chemical department of the Maryland institute. From 1854 to 1858 he was professor of analytical and applied chemistry in the university of Maryland, which post he resigned to remove to New York; and since 1864 he has resided in London, England. His principal works are: "Applied Chemistry in the Manufacture of Soaps and Candles" (Philadelphia, 1847); "Chemical and Pharmacautical Manipulations" (1848); "A Report of the Progress of the Chemical Arts," prepared with Prof. Booth for the Smithsonian institution (1851); "Perfumery, its Manufacture and Use" (1852-5); "Oleic Soaps" (London and New York, 1871); and "Mineral Phosphates" (1873). The last two are elaborately illustrated.

MORGAGNI, Giovanni Battista, an Italian anatomist, born in Forli, Feb. 25, 1682, died in Padua, Dec. 6, 1771. He took his degree of M. D. at Bologna, in 1711 became professor of the theory of physic at Padua, and in 1715 professor of anatomy. He is regarded as the founder of pathological anatomy. His works include Adversaria Anatomica (3 vols. 4to, Bologna and Padua, 1706-19), enlarged and published under the title of Adversaria Omnia (6 vols., Padua, 1741); and De Sedibus et Causis Morborum per Anatomiam Indagatis (3 vols., fol., 1761; 6 vols., Leipsic, 1827), translated into various languages.

MORGAN, the name of counties in 10 of the United States. I. A. N. E. county of West Virginia, bordering S. W. on Virginia, separated from Maryland by the Potomac, and drained by the Cacapon river; area, 350 sq. m.; pop. in 1870, 4,315, of whom 1,144 are Spaniards, and 1,122 are mules. The surface is mountainous, and the soil light and unproductive except in the valleys. There are large deposits of iron and coal. Berkeley Springs in this county is one of the oldest watering places in the United States. The Baltimore and Ohio railroad passes through the county. The chief productions in 1870 were 27,697 bushels of wheat, 58,142 of Indian corn, 19,885 of oats, 10,915 of potatoes, 7,564 lbs. of wool, 41,183 of butter, and 1,996 tons of hay. There were 882 horses, 1,112 milch cows, 1,456 other cattle, 2,683 sheep, and 2,523 swine. Capital, Bath. II. A central county of Georgia, bounded E. by Appalachchee and Oconee rivers, and drained by their branches; area, 272 sq. m.; pop. in 1870, 10,696, of whom 7,058 were colored. The surface is undulating, and the soil, based on limestone, is fertile. Small quantities of gold have been found, and there are large granite quarries. The county is intersected by the Georgia railroad. The chief productions in 1870 were 19,820 bushels of wheat, 129,948 of Indian corn, 14,325 of oats, 8,019 of sweet potatoes, 38,968 lbs. of butter, and 4,868 bales of cotton. There were 636 horses, 712 mules and asses, 1,144 milch cows, 1,979 other cattle, 1,969 sheep, and 3,762 swine. Capital, Madison. III. A N. county of Alabama, bounded N. by the Tennessee river; area, 729 sq. m.; pop. in 1870, 12,187, of whom 3,358 were colored. The surface is mountainous and the soil generally fertile. The Memphis and Charleston railroad passes through the N. W. part. The chief productions in 1870 were 23,336 bushels of wheat, 333,332 of Indian corn, 17,701 of oats, 19,902 of sweet potatoes, 4,389 bales of cotton, 6,747 lbs. of wool, 70,886 of butter, and 11,877 gallons of sorghum molasses. There were 2,462 horses, 660 mules and asses, 2,944 milch cows, 924 working oxen, 3,977 other cattle, 4,902 sheep, and 14,044
Pekin, and Jacksonville, the Great Western, and several other railroads. The chief productions in 1870 were 375,719 bushels of wheat, 3,198,855 of Indian corn, 198,724 of oats, 68,105 of potatoes, 77,156 of wool, 295,789 of butter, and 29,671 tons of hay. There were 10,530 horses, 5,648 milch cows, 28,809 other cattle, 15,040 sheep, and 44,583 swine; 12 manufactories of agricultural implements, 3 of boots and shoes, 5 of brick, 28 of carriages, 7 of furniture, 8 of saddlery and harness, 2 of cigars, 2 of woolen goods, and 11 flour mills. Capital, Jacksonville. IX. A central county of Missouri, bounded S. in part by Osage river and drained by some of its tributaries; area, 648 sq. m.; pop. in 1870, 8,434, of whom 307 were colored. The surface is diversified and in some places well wooded. The soil is generally fertile. Lead, coal, and limestone are found. The Missouri Pacific railroad skirts the N. border. The chief productions in 1870 were 83,123 bushels of wheat, 288,175 of Indian corn, 138,259 of oats, 16,424 of potatoes, 23,468 of wool, 41,353 of butter, and 2,909 tons of hay. There were 3,409 horses, 1,663 mules and asses, 2,771 milch cows, 5,630 other cattle, 10,366 sheep, and 11,493 swine. Capital, Versailles. X. A N.E. county of Utah, bounded S. by Weber river and its tributaries; area, 600 sq. m.; pop. in 1870, 1,972. It is crossed by the Union Pacific railroad. The chief resources are agricultural, but coal and iron are believed to exist. Gold mines have been recently opened. The chief productions in 1870 were 12,960 bushels of wheat and 3,900 of potatoes. The value of live stock was $40,490. There were 7 saw mills. Capital, Morgan.
for which he received a gold medal from congress, and followed it up by a series of well conceived manoeuvres which seriously embarrassed Cornwallis. Before the close of the campaign he was compelled by ill health to retire to his home in Virginia. He aided in quelling the whiskey insurrection in Pennsylvania in 1794, and was a member of congress from 1795 to 1799.

MORGAN, Sir Henry, a British buccaneer, born about 1837, died in Jamaica in 1890. He was the son of a farmer in Wales, became a sailor, and for many years maintained his position among the West India islands as chief of a host of pirates, composed of adventurers from all the nations of Europe. From his strongholds, one of which was the island of St. Catharine, he made many successful descents upon the Spanish settlements in his vicinity, and at sea captured many rich prizes. The most daring of these expeditions was that in which he captured and sacked Portobello and Panama, amassing a large fortune. (See Buc- caneers.) He afterward settled in Jamaica, where he was made a marine commissary and knighted by Charles II.

MORGAN, Lewis Henry, an American author, born in Ledyard, Cayuga co., N. Y., Nov. 21, 1818. He graduated at Union college in 1840, and studied law at Rochester, where he began to practise in 1844, and where he still resides. In 1864 he retired from practice. In 1851 he published "The League of the Iroquois," a full and accurate account of the Six Nations and their institutions. His researches among the Iroquois led him to observe their peculiar system of family relationship, which he found prevailed also among the tribes of the west, and of which in his ethnological studies he discovered unmistakable traces among the barbarous nations of the old world. This led him to institute investigations in all parts of the globe by means of letters and circulars addressed to missionaries and to United States ministers and consuls. The results of this correspondence were embodied in "Systems of Consanguinity and Affinity of the Human Family," published by the Smithsonian institution in 1870, which Sir John Lubbock pronounced "one of the most valuable contributions to ethnological science which have appeared for many years." In 1866 Mr. Mor- gan published "The American Beaver and his Works," the result of much observation of the beaver in the neighborhood of Lake Superior. In 1861 he was a member of the New York assembly, and in 1866-9 a state senator.

MORGAN. J. Sydney (Owensos), lady, an Irish authoress, born about 1738, died in London, April 13, 1859. Her father was an actor, and a man of considerable literary acquirements. In 1757 she published a volume of poems, followed by two tales, "St. Clair" (1804) and "The Notice of St. Dominick" (1805), and a novel, "The Wild Irish Girl" (1806), of which seven editions were printed in two years. In 1807 appeared her "Patriotic Sketches of Ireland" and "The Lay of an Irish Harp, or Metrical Fragments." In March of the same year her comic opera, "The First Attempt, or the Whim of a Moment," was brought out, with great success in the Theatre Royal, Dublin. In 1809 she published "Woman, or Ida of Athens;" and in 1811 "The Missionary." In 1812 she was married to Sir Thomas Charles Morgan, with whom she subsequently travelled over various parts of Europe, residing for considerable periods in France and Italy. Among the results of her travels were a review of the social state of France (4to, London, 1817), and a similar work on Italy (2 vols. 8vo, 1821), both of which caused much controversy. The popularity of these works introduced the authoress to the fashionable and literary circles of England. Among her remaining works were her novels, "O'Donnell" (1814), "Flor- ence Macarthy" (1816), "The Life and Times of Salvator Rosa" (1824), "Absenteism" (1825), and "The O'Byrnes and the O'Flaherty" (1827). "The Book of the Boudoir," containing several autobiographical and "Dramatic Scenes from Real Life" (1833); "The Princess, or the Béguine," written during a visit to Belgium (1835); "Woman and her Master" (1840); and "Passages from my Autobiography" (1858). Lady Morgan was one of the most brilliant conversationists of her time. She passed her last years at her residence in London, in the enjoyment of a pension of £200.—See W. J. Fitzpatrick's "Friends, Foes, and Adventures of Lady Morgan" (Dub- lin, 1859).

II. Sir Thomas Charles, an English author, husband of the preceding, born in London about 1728, died there, Aug. 28, 1848. He was educated at Eton and Cambridge, and in 1809 took the degree of M. D. He removed to Ireland, having a place under government as a commissioner of the Irish fisheries, was knighted in 1811, and in 1812 married Miss Owenson. Soon afterward he relinquished his profession for the pursuit of literature, and was an industrious contributor to periodicals. He is the author of "Sketches of the Philosophy of Life" (1818), and "Sketches of the Philosophy of Morals" (1822), and published in conjunction with his wife a collection of essays and miscellanies entitled "The Book without a Name" (1841). He farmed in Sicily, and appendices to Lady Morgan's first work on France.

MORGAN, William. See Anti-Masonry.

MORGANA. See Fata Morgana.

MORGANATIC MARRIAGE (Ang.-Sax. morgan gifu, Ger. Morgengabe, morning gift or dowry), the term for a marriage concluded between a man of superior and a woman of inferior rank, in which it is stipulated that the latter and her children shall be entitled neither to the rank nor to the possessions of the husband, the dowry (morning gift) being in lieu of all other privileges. Marriages of this kind are not infrequent in the princely houses of Germany, and one of the most noted was that of King
MORGARTEN

Frederick William III. of Prussia with the countess Auguste von Harrach, who thereupon received the title of princess of Liegnitz.

MORGARTEN, a hill in Switzerland, about 2 m. W. of Rothenthurm, on the margin of the lake of Egeri, and on the E. border of the canton of Zug, memorable as the scene of the battle of Nov. 16, 1315, in which a body of 1,400 Swiss mountainers from Schwytz, Uri, and Unterwalden, ill armed and undisciplined, totally vanquished an Austrian army of 20,000 under the duke Leopold. The hill overlooks a narrow pass between it and the lake. When the Austrians had entered this pass, a portion of the Swiss hurried down upon them immense masses of rock, which killed many and threw the cavalry into confusion; the remainder of the Swiss, stationed at the end of the pass, then charged them, and but few escaped. This was the first victory achieved by the Swiss in their struggle for freedom. A chapel stands at the foot of the hill, in which service is performed annually on the anniversary of the battle.

MORGENSTERN, Christian, a German painter, born in Hamburg in 1806, died Feb. 26, 1867. His parents were poor, and he began life as assistant of an engraver of panoramas. In 1823 he was admitted to the school of painting of Bendixen, and in 1827 he exhibited his first work, "Oaks near a Swamp," which procured for him a small stipend from the government. He spent some time in Holstein, explored Norway, attended the academy of fine arts at Copenhagen, and settled in Munich in 1830, choosing the "Heath of Lüneburg" as the theme of his first work in that city. He produced exquisite landscapes of the mountains of Berchtesgaden and Salzburg, of the romantic castles of Alsace and the Voges mountains, of Lakes Starnberg and Chiem, and of Heligoland. His pictures of moonlight and stormy nights on Heligoland are regarded as his masterpieces. Shortly before his death he exhibited in Paris a new painting of the heath of Lüneburg. He also excelled in etching.

MORGEN, Rafaele Sanzi, an Italian engraver, born in Florence, June 19, 1788, died there, April 8, 1833. He was instructed by his father, an engraver, and at 20 years of age executed a series of seven plates representing masks from the carnival of Naples of 1778. He was then placed in the school of Volpato in Rome, and in 1781 married the only daughter of his master. In 1787 he produced his engraving of Guido's "Aurora." He visited Naples in 1790, and removed in 1793 to Florence, where he opened a public school of engraving. His first important work in Florence was the print of Raphael's Madonna della seggiola, and in 1795 he commenced the Madonna del sacco of Andrea del Sarto, and the "Transfiguration" of Raphael, the latter his most elaborate work, completed in 1812. But this is considered less meritorious than his print of the "Last Supper" after Leonardo da Vinci, the early impres-

sions of which (1800) are among the most precious productions of his graver. According to his pupil Nicolò Palmerini, to whom he gave impressions of every plate from the first outline to the finished proof, Morgren executed 73 portraits, many of which were of living personages besides the great poets and painters of Italy, 47 Biblical and religious pieces, 44 historical and mythological pieces, 24 views and landscapes, and 13 vignettes and crests. The Palmerini collection of his prints was purchased by the duke of Buckingham for £1,200.

MORGUE (from the Languedocian morpa, a repulsive face), a place for the exhibition of dead bodies of unknown persons, with a view to their identification. Such establishments existed in Paris as early as the 17th century, in connection with prisons. The one in the Châtelet was succeeded in 1804 by a separate establishment, which was enlarged in 1830; but this proving inadequate, another was opened in 1866 close by the Seine, behind the cathedral of Notre-Dame. It consists of a central pavilion and two wings. The dead are placed inside a glazed partition, on slabs of marble, and streams of water and other means are employed to delay decomposition. The average period of exhibition is 24 hours, and the greater number of the bodies are recognized. When there is evidence of death by violence, the bodies are examined in the dissecting room. The burial of the unrecognized and poor is at the public expense in special lots in the cemeteries. The effects not claimed by relatives are retained for six months. The following table shows the number exposed in ten years:

Besides these, there were 94 fragments, 296 fetuses, and 197 new-born infants; the number of the last has greatly increased of late years, in consequence of the suppression of deposit boxes in foundling hospitals. In the whole number there were 1,766 suicides, most of them recovered from the Seine. A majority of these were natives of Paris, of the poorest classes. The annual average is about 250 adult males and 50 females, but is much larger in time of epidemics and disturbances. It has been exceptionally large since the Franco-German war, the suicides increasing from 567 in 1872 to 660 in 1873, and to nearly 1,000 in 1874. The morgue in New York was established in June, 1866. It is on the grounds of Bellevue hospital, and is under the charge of the warden of the hospital, a keeper, and an assistant. As soon as a corpse is brought in, a full account of its recovery, when and where found, a description, and other particulars are
recorded. Notice is sent to the coroner, and if there are indications of a violent death the case is reported to the superintendent of police. Recognized bodies, by permission of the coroner, are removed by friends; those unrecognized are exposed on marble slabs, under streams of water, for 72 hours, or less at the discretion of the warden. Photographs are taken for the inspection of persons in search of missing friends. The clothing is exhibited 30 days, and kept another year. Unrecognized bodies are buried in the city cemetery on Hart's island, and numbers and records permit their identification and removal. In no case is a corpse devoted to dissection. On the first day of each month the warden makes a detailed report of all bodies, identified or not, to the commissioners of public charities and correction. From June, 1866, to Oct. 19, 1874, 1,283 bodies were received, of which more than one half were recognized and removed by friends. Nearly three fourths were bodies of persons drowned, a large proportion of them while bathing. From January to October, 1874, there were brought from the rivers to the morgue 127 males and 17 females, of whom 101 males and 11 females were found in May, June, July, and August, leaving but 26 males and 6 females for the five colder months. But in New York, as in Paris and elsewhere, the warm months are selected by suicides who drown themselves. A considerable number of those who are drowned purposely or by accident or are murdered and thrown into the East or North river, are not recovered, but are carried away by the tide. Of infants dead from neglect or other causes at time of birth, and of fetuses, only a few are taken to the morgue. The morgue in Brooklyn, N. Y., was erected in 1870 at a cost of $25,000, and is the most complete building of the kind in the country. It is in Willoughby street, in the rear of the jail, and, with every convenience for the exhibition and preservation of bodies, contains rooms for post-mortem examinations, a large jurors' court room, which can be used as a chapel for funerals, and residence rooms for the keeper and his family. It is under the supervision of the coroners. The rules and regulations are substantially those of the New York morgue. Minute descriptions of the unrecognized are published in two of the city newspapers. In no case is a corpse given up for dissection till every means of identification has been exhausted. The number of bodies averages 150 a year, more than half of them drowned, and there is in addition an annual average of about 50 dead infants and fetuses. The number of bodies recognized and removed by friends in four years is as follows: 62 in 1871, 91 in 1872, 142 in 1873, and 45 to Sept. 1, 1874. In 1874, to the same date, 101 bodies, some of them recognized, were buried from the morgue at public expense. The morgue in Chicago, Ill., is on the grounds of the Cook county hospital, and was opened June 1, 1872. It is in charge of the warden of the hospital, under the supervision of the superintendent and medical director of public charities. The rules and regulations are nearly identical with those of the New York morgue. A law which went into effect July 1, 1874, permits the devotion of unrecognized bodies to dissection. The receipt of bodies has been as follows: 70 males and 7 females in 1872, 94 males and 9 females in 1873, and 102 males and 2 females in 1874. Of these, 22 were infants dead from neglect or other causes at time of birth, and there were in addition 6 fetuses. Of 261 deaths in three years, 105 were caused by drowning, 52 by railway accidents, 23 by suicide, and 81 resulted from other causes; and 212 bodies were recognized. The morgue in Boston, Mass., was opened in 1861, near the Massachusetts general hospital, and is in charge of an undertaker. A coroner is called to determine whether deaths are by violence, suicide, or accident. Bodies are exposed 48 hours or longer, and descriptions are recorded, garments exhibited and preserved, and notices inserted in the newspapers. Photographs are taken. Unclaimed bodies are buried at public expense. Statute law forbids devoting unknown bodies to dissection. Reports are made to the city registrar. About 100 bodies are annually received, and about two thirds of them are recognized. No infants are sent to the morgue, unless inquests are necessary; they are delivered to the city undertaker for burial. —An ordinance adopted in St. Louis, Mo., in September, 1874, provides for the establishment of a morgue in that city.

MORIEH, Daniel Georg, a German scholar, born in Wismar, Feb. 6, 1839, died in Lubeck, June 30, 1891. He became a merchant at Rostock in 1860, and at Kiel in 1865, professor of history in 1873, and librarian in 1880. He was a voluminous author, and his principal work, Polyhistor, part of which appeared in his lifetime (Lubeck, 1868), was published complete in 1704, and was for a long time a standard work on universal literature.

MORIAH, Mount. See JERUSALEM.

MORIER, James, an English author, born about 1780, died in Brighton, March 30, 1849. He studied the oriental languages, spent about six years (1810-16) in Persia as secretary of legation and minister plenipotentiary, and published "Travels in Persia, Armenia, and Asia Minor to Constantinople" (London 1812); "A Second Journey through Persia, Armenia, and Asia Minor" (1818); and a series of novels, the most interesting of which is "The Adventures of Hajji Baba" (5 vols., 1824-8). Among his other works are "Zohrab, or the Hostage" (1832), "Ayesha, the Maid of Kars" (1834), and "The Mirza" (1841), all illustrations of Persian life.

MORIKE, Eduard, a German poet, born at Ludwigslust, Wurttemberg, Sept. 8, 1804. He attended the gymnasion of Stuttgart, prepared himself at Urach and Tübingen for the minis-
try, and was for a while a pastor. But ill health impelled his retirement, and he was a teacher at Stuttgart till 1866. He is one of the best of the Swabian poets, and has made excellent translations of Anacreon and Theocritus. His works include *Gedichte* (Stuttgart, 1882); *Gedichte* (1833; 4th ed., 1867); *Idylle vom Bodensee* (1846; 2d ed., 1856); *Das Stuttgarter Hutzwintmlein, a fairy tale* (1853); *Vier Erzählungen; and Mozart auf der Reise nach Porg*, a novel (1856). Lachner set to music his opera *Die Regenbrüder*, and Hetsch and F. Kauffmann many of his songs and ballads.

**MORLAKS**, the name of a portion of the Slavic population of Dalmatia and the adjoining maritime districts of Austro-Hungary. They are skilful mariners, and form a large portion of the sailors in the Austrian navy. The coast of the Adriatic between Carlcopag and Zengg is from them called Morlacka, and the strait between it and the islands of Veglia, Arbe, and Pago the strait of Morlacka.

**MORLAND, George**, an English painter, born in London about 1764, died there, Oct. 29, 1804. His father was an artist, under whose direction he made pictures and drawings for sale. When 21 he left his father's house and pursued his art alone, reaching the full maturity of his powers about 1790, after which period he gave himself up to intemperance and profligacy. During the last few years of his life he was seldom sober, and painted only to supply his actual necessities. Many of his later works were executed in sponging houses, in one of which he died. His subjects were generally selected from low life, and he acquired an astonishing skill in painting domestic animals, especially pigs. He was also very successful in delineating the more common species of English landscape. His execution deteriorated greatly toward the close of his life, but his pictures were nevertheless in such demand that a regular manufactory of imitations of them was established by his brother Henry.

**MORLEY, Henry**, an English author, born in London, Sept. 15, 1822. He was sent to a Moravian school at Newield on the Rhine, and graduated at King's college, London, where he established and edited the "King's College Magazine." He practised medicine in Shropshire from 1843 to 1848. Beginning in 1847, he has published numerous papers on public health. From 1851 to 1857 he was Dickens's assistant in editing "Household Words," and from 1856 to 1859 joint editor of the London "Examiner," of which he was sole editor from 1859 to 1864. In 1859 he became professor of English literature in King's college, and in 1865 in University college. He was the most active promoter of the association formed in 1869 for the education of women in connection with the latter institution. His principal publications in book form are: "The Dream of the Lily Bell," tales and poems (1845); "Sunset in Italy," poems, and "Tracts upon Health, for Cottage Circulation" (1847); "A Defence of Ignorance" (1851); "Life of Bernard Palissy of Saintes" (2 vols., 1832); "Life of Jerome Cardan" (1854); "Life of Henry Cornelius Agrippa" (1856); "Gossip and Memoirs of Bartholomew Fair" (1857); "A History of English Literature" (2 parts published, 1864 and 1867, the first devoted to writers before Chaucer, the second reaching from Chaucer to Dunbar); "Steele and Addison's Spectators, original and corrected texts" (1868); "Table of English Literature" (1870); "Clément Marot, and other balladiers" (1871); and "A First Sketch of English Literature" (3 vols., 1873).

**MORLEY, John**, an English author, born in Blackburn, Lancashire, Dec. 24, 1838. He graduated at Lincoln college, Oxford, in 1859, early became a contributor to the "Saturday Review," and in 1867 succeeded George Henry Lewes as editor of the "Fortnightly Review." He published "Edmund Burke, a Historical Study," in 1857, "Critical Miscellanies," including essays on De Maistre, Condorcet, Carlyle, and Byron, in 1871, and in the latter year also a volume on Voltaire. In April, 1872, he delivered at the London royal institution a lecture on Rousseau, which was afterward elaborated into two volumes (1873). In 1873 he delivered a series of lectures on "The Limits of the Historic Method." In that year also he was active in resisting the educational system introduced by the Gladstone government, because of its denominational character, and published "The Struggle for National Education." His latest work is "On Compromise" (1874).

**MORLEY, Thomas**, an English composer, died in London at an advanced age about 1604. He graduated as a bachelor of music at Oxford in 1588, and was made gentleman of Queen Elizabeth's chapel in 1592. He was a pupil of William Birde and a student of the forms of the Italian madrigal writers. His works consist of canzonets, madrigals, anthems, and church services. In imitation of Giovannelli, who had employed 37 of the most celebrated Italian composers to write madrigals in honor of the Virgin Mary, Morley obtained from English composers 24 madrigals in praise of Queen Elizabeth under the name of Oriana, entitling the collection "The Triumphs of Oriana, to five and six voices, composed by divers several authors, newly published by Thomas Morley, Bach, of Musicae and Gentilins of her Majesty's honorable Chapel" (1601). Among the composers represented in this collection were John Milton, father of the poet, Wilbye, and Benet. Morley wrote also a treatise of much value entitled "A Plaine and Easy Introduction to Practical Musicke."

**MORMONS, or Latter Day Saints**, a sect founded by Joseph Smith, who was born at Sharon, Vt., in 1805, and was killed at Carthage, Ill., in 1844. (See Smith, Joseph.) According to his own account, Smith at about the age of 16, while living with his father, who was a
farmer in Ontario (now Wayne) co., N. Y., began to have visions. On the night of Sept. 21, 1823, the angel Moroni appeared to him three times, informing him that God had a work for him to do, and that a record written upon gold plates, and giving an account of the ancient inhabitants of America and the dealings of God with them, was deposited in a particular place in the earth (a hill in Manchester, Ontario co., N. Y.), and, with the record, two transparent stones in silver bows like spectacles, which were anciently called the Urim and Thummim, on looking through which the golden plates would become intelligible. On Sept. 22, 1827, the angel of the Lord placed in Smith's hands the plates and the Urim and Thummim. The plates were nearly 8 in. long by 7 in. wide, and a little thinner than ordinary tin, and were bound together by three rings running through the whole. Altogether they were about 6 in. thick, and were neatly engraved on each side with hieroglyphics in a language called the reformed Egyptian, not then known on the earth. From these plates Smith, sitting behind a blanket hung across the room to keep the sacred records from profane eyes, read off, with the aid of the stone spectacles, the "Book of Mormon," or Golden Bible as he sometimes called it, to Oliver Cowdery, who wrote it down as Smith read it. It was printed in 1830, in a volume of several hundred pages. appended to it was a statement signed by Oliver Cowdery, David Whitmer, and Martin Harris, who had become prosessed believers in Smith's supernatural pretensions, and are called by the Mormons "the three witnesses." They said: "We declare with words of soberness that an angel of God came down from heaven, and he brought and laid before our eyes that we beheld and saw the plates and the engravings thereon." Several years afterward all three of these witnesses quarreled with Smith, renounced Mormonism, and avowed the falsity of their testimony. Immediately on the appearance of the "Book of Mormon" many of Smith's neighbors testified that he had repeatedly made contradictory statements about the plates and the Golden Bible. The "Book of Mormon" is a collection of 16 distinct books professing to be written at different periods by successive prophets. Its style is a verbose imitation of that of the common English translation of the Bible, portions of which, to the number in all of 300 passages, are incorporated without acknowledgment, and are frequently cited by Mormons as specimens of the book. A multitude of names are introduced, some Hebrew and Biblical, others Greek and Latin, and the rest imitations of the former. The first book professes to be the work of Nephi, a Jew, the son of Lehi, who dwelt at Jerusalem in the days of King Zedekiah, about 600 B. C. In obedience to the command of the Lord, who appeared to him in a dream, he went into the wilderness of Arabia and dwelt there a long time with his family. At length, still under divine instruction, Lehi and his family set out in search of a promised land, and after travelling "nearly eastward" for eight years, "through a wilderness," they reached the ocean. Here they built a ship, and, guided by a compass, sailed to America. The Book of Mormon itself gives no indication of the part of the continent on which they landed, but later Mormon interpretations or revelations declare it to have been the coast of Chili. Those who arrived in America were Lehi and his wife, his four sons, Laman, Lemuel, Sam, and Nephi, and their four wives, two "sons of Ishmael" and their two wives, and Zoram, a servant, and his wife; in all, eight adult men with as many wives. Besides these, there were two infant sons of Lehi born during the journey through the wilderness, Jacob and Joseph. In America they found "beasts in the forest of every kind, both the cow, and the ox, and the ass, and the horse, and the goat." Soon after his arrival in America Lehi died, and dissensions speedily ensued between Nephi and his elder brothers Laman and Lemuel; and, separating from them, Nephi moved into the wilderness accompanied by Sam and Zoram and their families, the boys Jacob and Joseph, and such of the women and children as took his side. Laman and Lemuel and the "sons of Ishmael" and their families, as a punishment for rebelling against Nephi, whom the Lord had appointed to be their ruler, were cursed by the Lord, and they and all their posterity condemned to have dark skins and to "become an idle people, full of mischief and subtility, which did seek in the wilderness for beasts of prey." This was the origin of the American Indians, who are consequently believed by the Mormons to be of Jewish race. Nephi died about 50 years after his arrival in America, and his people continued to be called Nephites and to be governed by kings bearing the name of Nephi for many generations. The record of their history was continued on golden plates by Jacob the brother of Nephi, Enos the son of Jacob, Jarom the son of Enos, Omni the son of Jarom, and finally by Mormon, whose name is given to a single book, as well as to the whole volume, and who, "many hundred years after the coming of Christ," transmitted to his son Moroni the plates containing the writings of the authors already mentioned, together with those of Mosiah, Zeniff, Alma, Helaman, Nephi the Second, and Nephi the Third. These books consist almost wholly of a narrative of transactions in North and South America, chiefly of wars between the Nephites and the Lamanites or red men, and of revolutions in the land of Zarahemla, which was near the isthmus of Darien, where there was an exceeding great city. At length, in the days of Nephi the Second, a terrible earthquake announced the crucifixion of Christ at Jerusalem, and three days afterward the Lord himself descended out of heaven into the chief

city of the Nephites, in sight of all the people, to whom he exhibited his wounded side and the prints of the nails in his hands and feet. He remained among them 40 days, instructing them in Christianity and instituting Christian churches. The Christians of America, unlike their brethren in the old world, immediately adopted the Christian era for their chronological computations; and according to the record, in the four following centuries the wars between them and the heathen Lamanites continued to rage, with great destruction of the Christians, whose populous and civilized cities, which were very numerous throughout North America, were gradually captured and destroyed. In the year 88 A.D. the Christians made their final stand on the hill Cumorah, in western New York, where in a great battle 230,000 of them were slain. Moroni, one of the survivors, after wandering a fugitive till A. D. 420, sealed up the golden plates on which all these things were written, and hid them in the hill where they were found by Joseph Smith. One of the books in the collection, the book of Ether, gives an account of an earlier settlement of America than that of Lehi, by a colony from the tower of Babel, soon after the deluge, which was led by Jared, and in time became a great nation, which was destroyed for its sins before the arrival of the colony from Jerusalem.—The religious teachings of the "Book of Mormon" relate in great part to doctrinal questions that were rife in the villages of western New York about 1830. Calvinism, Universalism, Methodism, Milennialism, Roman Catholicism, and other modern forms of belief, are discussed. Infant baptism is warmly condemned, and polygamy is repeatedly denounced. According to the opponents of Mormonism, from investigations made soon after the appearance of the "Book of Mormon," the fact is fully established that the real author of the work was Solomon Spalding, who was born in Ashford, Conn., in 1761, graduated at Dartmouth college in 1788, was ordained, and preached for three or four years. Relinquishing the ministry, he engaged in mercantile business at Cherry Valley, N. Y., whence in 1809 he removed to Conneaut, Ohio. In 1812 he removed to Pittsburgh, and thence in 1814 to Amity, Pa., where he died in 1816. He wrote several novels, which he was in the habit of reading to his friends in manuscript, as they were so worthless that he could find no publisher for them, while his poverty prevented him from issuing them at his own expense. During his residence in Ohio in 1810-'12 he wrote a romance to account for the peopling of America by deriving the Indians from the Hebrews, in accordance with a notion then prevalent in some parts of the country that the American Indians were descended from the lost tribes of Israel. As early as 1813 this work was announced in the newspapers as forthcoming, and as containing a translation of the "Book of Mormon." Spalding entitle his book "Manuscript Found," and intended to publish it by way of preface or advertisement a fictitious account of its discovery in a cave in Ohio. His widow published a statement in the "Boston Journal," May 18, 1839, declaring that in 1812 he placed his manuscript in a printing office at Pittsburgh, with which Sidney Rigdon was connected. Rigdon, she says, copied the manuscript; and his possession of a copy was known to all in the printing office, and was often mentioned by himself. Subsequently the original manuscript was returned to the author, who soon after died. His widow preserved it till after the publication of the "Book of Mormon," when she sent it to Conneaut, where a public meeting, composed in part of persons who remembered Spalding's work, had requested her to send the manuscript that it might be publicly compared with the "Book of Mormon." She says in conclusion: "I am sure that nothing would grieve my husband more, were he living, than the use which has been made of his work. The air of antiquity which was thrown about the composition doubtless suggested the idea of converting it to the purposes of delusion. Thus, a historical romance, with the addition of a few pious expressions, and extracts from the sacred Scriptures, has been constructed into a new Bible, and palmed off upon a company of poor deluded fanatics as divine." Sidney Rigdon was born in St. Clair township, Allegheny co., Pa., Feb. 19, 1793. Soon after getting possession of a copy of Spalding's manuscript, he quit the printing office and became a preacher of doctrines peculiar to himself, and very similar to those afterward incorporated into the "Book of Mormon." He had a small body of converts to his notions when about 1829 he became associated with Joseph Smith, who was then endeavoring to gain believers to his tale of the golden plates and stone spectacles. It is asserted that through Rigdon's agency Smith became possessed of a copy of Spalding's manuscript, which he read from behind the blanket to his amanuensis Oliver Cowdery, with such additions as suited the views and purposes of Rigdon and himself. Immediately on its publication, the "Book of Mormon" was recognized not only by Spalding's widow but by many of his friends as his long lost work. The printing of the "Book of Mormon" was done at the expense of Martin Harris, who had some property, and was persuaded that he could make money by the speculation. While the work was in progress this man called upon Prof. Anthon of New York with a transcript on paper which Smith had given him of the characters on one of the golden plates. "This paper," Prof. Anthon says in a letter dated New York, Feb. 17, 1834, "was in fact a singular scroll. It consisted of all kinds of crooked characters, disposed in columns, and had evidently been prepared by some person who had before him at
the time a book containing various alphabets. Greek and Hebrew letters, crosses and flourishes, Roman letters, inverted or placed sideways, were arranged and placed in perpendicular columns; and the whole ended in a rude delineation of a circle, divided into various compartments, decked with various strange marks, and evidently copied after the Mexican calendar given by Humboldt, but copied in such a way as not to betray the source whence it was derived." This letter was written to contradict a report set afloat by Smith that Prof. Anthon had pronounced the characters to be Egyptian hieroglyphics.—Smith and Rigdon seem at first to have had vague and confused ideas as to the nature and design of the church they were about to establish. They were both inclined to teach millenarianism, which at that time was beginning to attract attention in western New York; and they accordingly settled into the doctrine that the millennium was close at hand, that the Indians were to be speedily converted, and that America was to be the final gathering place of the saints, who were to assemble at New Jerusalem, as it was now styled, somewhere in the interior of the continent. With the "Book of Mormon" as their text and authority, they began to preach this new gospel; and Smith's family and a few of his associates, together with some of Rigdon's previous followers, were soon numerous enough to constitute the Mormon church, as it was styled by the people around them, or the church of Latter Day Saints, as they presently began to call themselves. The church was first regularly organized at Manchester, N. Y., April 6, 1830, and the first conference was held at Fayette, N. Y., in June, at which time the number of members had increased to 390. Smith, directed as he said by revelation, in January, 1831, led the whole body of believers to Kirtland, Ohio, which was to be the seat of the New Jerusalem. Here converts were rapidly made, and soon, desiring a wider field for the growth of the church, Smith and Rigdon travelled westward, looking for a suitable location, which was found in Independence, Jackson co., Mo., where in August Smith dedicated a site for the temple to be erected by the saints, and named the place New Jerusalem. On their return to Kirtland, where they proposed to remain for five years "and make money," Smith and Rigdon established a mill and a store, and set up a bank without a charter, of which Smith appointed himself president, and made Rigdon cashier. The neighboring country was flooded with notes of very doubtful value; and in consequence of this and other business transactions in which Smith and Rigdon were accused of fraudulent dealing, a mob on the night of March 22, 1832, dragged the two prophets from their beds, and tarred and feathered them. About a year afterward a government for the church was instituted, consisting of the prophets, Smith, Rigdon, and Frederick G. Williams, who together were styled the first presidency, a revelation from the Lord having declared that the sins of Rigdon and Williams were forgiven, "and that they were henceforth to be accounted as equal with Joseph Smith, jr., in holding the keys of his last kingdom." About this time Brigham Young, a native of Vermont, a painter and glazier about 30 years of age, became a convert to Mormonism. (See Young, Brigham.) He arrived at Kirtland toward the close of 1832, and was soon ordained an elder, and began to preach. His talent and shrewdness speedily made him prominent, and in February, 1835, when a further step was taken in the organization of a hierarchy by the institution of the quorum of the twelve apostles, he was ordained one of the twelve, and sent out with the other apostles to preach the new doctrines. His field of labor was the eastern states, and he was signal success in making converts. In 1836 a large and costly temple, which had been for three years in process of building, was consecrated at Kirtland; and in 1837 Orson Hyde and Heber C. Kimball, the latter of whom had been a Mexican, arrived in New Jersey, and became connected with the congregation there. The conflicts with the Missourians still continued, and many outrages were committed and several persons killed on both sides. In the midst of their external troubles, internal dissensions broke out among the Mormons. Several of their leading men apostatized and accused Smith of gross crimes and frauds. On Oct. 24, 1838, Thomas B. Marsh, president of the 12 apostles, and Orson Hyde, also one of the apostles, made before a justice of the peace in Ray co., Mo., an affidavit in which March said, corroborated by Hyde: "They have among them a company, consisting of all that are considered true Mormons, called the Danites, who have taken an oath to support the heads of the church in all things that they say or do, whether right or wrong. . . . The plan of said Smith, the prophet, is to take this state; and he professes to his people to intend taking the United States, and ultimately the whole world. This is the belief of the church, and my own opinion of the prophet's plan and intentions. The prophet inculcates the notion, and it is believed by every true Mormon, that Smith's prophecies are superior to the law of the land. I have heard the prophet say that he would proceed down to his enemies and walk over their dead
bodies; that if he was not let alone he would be a second Mahomet to this generation, and that he would make it one gore of blood from the Rocky mountains to the Atlantic ocean." The defeat of God and his angels to witness this day, that we warn all men in the name of Jesus Christ to come on us no more for ever. The man, or the set of men, who attempts it, does it at the expense of their lives. And that mob that comes on us to disturb us, it shall be between them and us a war of extermination, for we will follow them till the last drop of their blood is spilt, or else they will have to exterminate us. For we will carry the seat of war to their own houses, and their own families, and one party or the other shall be utterly destroyed." Toward the close of 1838 the conflict between the Mormons and the Missourians assumed the character and proportions of civil war. The Mormons armed themselves, and, assembling in large bodies, fortified their towns and defied the officers of the law. The militia of the state was called out by the governor, and Rigdon and Smith were arrested, charged with treason, murder, and felony. The forces of the state being overwhelming in number, the Mormons capitulated and agreed to quit Missouri, and to the number of several thousands crossed the Mississippi into Illinois. They were soon after joined by Smith, who broke out of the jail where he had been confined awaiting trial. Rigdon had previously been liberated by a writ of habeas corpus. The Mormons were kindly received in Illinois, and Dr. Isaac Galland, who owned a large tract of land in Commerce, in Hancock co., gave Smith a considerable portion of it in order to enhance the value of the rest by the settlement of the Mormons there. Smith accordingly received a revelation commanding the saints to establish themselves at Commerce, and build a city to be called Nauvoo on the land presented to him, which he divided into house lots and sold to his followers at high prices. By this transaction, and by other equally successful speculations, the prophet in a few years amassed a considerable fortune. Nauvoo soon grew to be a city of several thousand inhabitants, the saints being summoned by a new revelation to assemble there from all quarters of the world, and to build a temple for the Lord, and a hotel in which Smith and his family should "have place from generation to generation, for ever and ever." The legislature of Illinois granted a charter for the city of Nauvoo, conferring upon it extraordinary privileges, which enabled Smith, Rigdon, and the other leaders to exercise almost unlimited civil power. They were authorized by charter to form a military body, which was accordingly formed under the name of the Nauvoo legion, and comprised nearly all the Mormons capable of bearing arms. Smith was commander of this force with the rank of lieutenant general. Besides this office, he held those of mayor of the city and first president of the church. By a revelation given April 6, 1830, he had been appointed "seer, translator, prophet, apostle of Jesus Christ, and elder of the church:" and the Lord had said to him: "The church shall give heed to all his words and commandments which he shall give unto you; for his word shall ye receive as if from my own mouth, in all patience and faith." The civil and military offices which he conferred upon himself at Nauvoo and the legion at his command gave him supreme power within the city, whose charter had been purposely so framed that the state authorities were almost excluded from jurisdiction within its limits. On April 6, 1841, the foundation of the temple was laid at Nauvoo, by Lieut. Gen. Smith, who appeared at the head of the legion, surrounded by a numerous military staff; and the saints being commanded by revelation not only to contribute to its erection, but to labor personally upon the work every tenth day, its walls rapidly arose.—In 1838 Smith had persuaded several women to cohabit with him, calling them his spiritual wives, although he had a lawful wife to whom he had been married in 1827. His wife became jealous of these rivals, and to pacify her Smith received, July 12, 1843, a revelation authorizing polygamy. This fact being whispered at Nauvoo, much scandal was created in consequence. The imputation was strenuously denied in public, and in 1845 the heads of the church deemed it prudent to put forth a formal denial in the following words: "Inasmuch as this church of Christ has been reproached with the crimes of fornication and polygamy, we declare that we believe that one man should have but one wife, and one woman but one husband; except in case of death, when either is at liberty to marry again." It was not till 1852 that they admitted the truth, and boldly avowed and defended polygamy on the authority of the revelation of 1845. Meantime Smith in 1843 and 1844 made advances to so many women in Nauvoo, soliciting them to become his spiritual wives, that great uproar was created by the declarations of those whose virtue was proved against his attempts. Among others who repelled and denounced him publicly was Mrs. Foster, wife of Dr. Foster. Her husband, together with William Law and others who had been similarly outraged, denounced Mormonism, and commenced at Nauvoo the publication of a newspaper, the "Expositor," to expose Smith. In the first number they printed the affidavits of 16 women to the effect that Joseph Smith, Sidney Rigdon, and others had endeavored to convert them to the spiritual wife doctrine, and to seduce them under the plea of having had special commission from heaven. This publication created great excitement, and on May 6, 1844, Smith and a party
of his followers attacked the "Expositor" office and razed it to the ground, destroying the presses and other contents of the building. Foster and Law took refuge in Carthage, the county seat, where they obtained warrants against Joseph Smith, his brother Hyrum Smith, and 16 others. The warrant was served upon Smith, but he refused to obey, and the constable who served it was driven from Nauvoo. The county authorities called out the militia to enforce the law; the Mormons armed themselves, and a civil war seemed impending, when the governor of the state persuaded the two Smiths to surrender and take their trial. They were committed to the jail at Carthage, and a guard stationed for their protection. On the evening of June 27 a mob attacked the jail, overpowered the guard, and fired upon the prisoners with rifles through a window and door. Hyrum Smith was instantly shot dead. Joseph returned the fire with a revolver till his charges were exhausted, and then attempted to escape through the window, but was shot as he leaped through it and fell to the ground dead. The death of the prophet caused much temporary confusion among the saints. Sidney Rigdon aspired to succeed him as head of the church; but Brigham Young was not opposed, and Rigdon, being contumacious, was cut off from the communion of the faithful, cursed, and solemnly delivered to the devil "to be butchered in the flesh for a thousand years." In 1845 the charter of Nauvoo was repealed by the legislature of Illinois, and the Mormons made preparations to remove to the Rocky mountains. Early in the following year they gathered in considerable numbers at Council Bluffs, Iowa. Those who remained in Nauvoo became again involved in trouble with the surrounding people, and in September, 1846, the city was cannonaded for three days, and the inhabitants were driven out at the point of the bayonet. In the following year pioneers crossed the plains from Council Bluffs to Salt Lake valley, Utah, where Brigham Young arrived July 24, 1847. In May, 1848, the main body of the saints set out for Utah, and arrived at the Great Salt lake in the autumn. Salt Lake City was founded (see SALT LAKE CITY), and large tracts of land were brought under cultivation. An "emigration fund" was established, and large numbers of converts were brought by a well organized system from Europe, chiefly from the working classes of Great Britain, and especially from Wales. A considerable number came also from Sweden and Norway, and a smaller number from Germany, Switzerland, and France. In March, 1849, a convention was held at Salt Lake City and a state organized under the name of Deseret, understood by the Mormons to signify "the land of the honey bee." A legislature was elected and a constitution framed and sent to Washington; but congress refused to recognize the new state, and in September, 1850, organized the country occupied by the Mormons into the territory of Utah, of which Brigham Young was appointed governor by President Fillmore. In the following year the federal judges were forced by threats of violence from Brigham Young to quit Utah, and the laws of the United States were openly defied and subverted. This led to the removal of Brigham Young, and the appointment of Col. Steptoe of the United States army as governor. Col. Steptoe arrived in Utah in August, 1854, with a battalion of soldiers; but such was the state of affairs in the territory that he did not deem it prudent to assume the office of governor, and after wintering in Salt Lake City he formally resigned his post and removed with his troops to California. In a sermon preached in the tabernacle at Salt Lake City on the Sunday after Col. Steptoe's departure, Brigham Young said: "I am and will be governor, and no power can hinder it, until the Lord Almighty says: 'Brigham, you need not be governor any longer.'" Most of the civil officers who were commissioned about the same time with Col. Steptoe arrived in Utah a few months after he had departed. They were harassed and terrified like their predecessors. In February, 1856, a mob of armed Mormons, instigated by sermons from the pulpit of the church, broke into the court room of the United States district judge, and at the point of the bowie knife compelled Judge Drummond to adjourn his court sine die. Soon afterward all the United States officers, with the exception of the Indian agent, were forced to flee from the territory. These and similar outrages at length determined President Buchanan to supersede Brigham Young in the office of governor, and to send to Utah a military force to protect the federal officers and to compel obedience to the laws. The Mormons attempted to justify their treatment of the United States officials, by alleging that they had been assaulted by "unfittable persons; an accusation which they attempted to sustain by scandalous statements which were probably not entirely destitute of truth. In 1857 the office of governor of Utah was conferred upon Alfred Cumming, a superintendent of Indian affairs on the upper Missouri, and that of chief justice on Judge Eckels of Indiana; and a force of 2,500 men under experienced officers was sent to protect them in the discharge of their functions. The Mormons were greatly excited at the approach of these troops. Young in his capacity of governor issued a proclamation denouncing the army as a mob, and forbidding it to enter the territory, and calling the people of Utah to arms to repel its advance. The army reached Utah in September, and on Oct. 5 and 6 a party of mounted Mormons destroyed several of the supply trains, and a few days later cut off 800 oxen from the rear of the army and drove them to Salt Lake City. The army, of which Col. A. S. Johnston had by this time assumed the command, was overtaken by the snows of winter.
before it could reach Salt Lake valley, and about the middle of November went into win-
ter quarters on Black's Fork near Fort Bridger. On Nov. 27 Gov. Cumming issued a proclaama-
tion declaring the territory to be in a state of
rebellion. In the spring of 1858, by the inter-
vention of Mr. Thomas L. Kane of Pennsyl-
vania, who had gone to Utah by way of Cal-
ifornia, bearing letters from President Buchan-
an, a good understanding was brought about
between Gov. Cumming and the Mormon lead-
ers; and toward the end of May two commis-
sioners, Gov. Powell of Kentucky and Major
McCulloch of Texas, arrived at the camp with
a proclamation from the president, offering
pardon to all Mormons who would submit
themselves to federal authority. This offer
was accepted by the heads of the church, and
shortly afterward the troops entered Salt Lake
valley, and were stationed at Camp Floyd on
the western side of Lake Utah, about 40 m.
from Salt Lake City, where they remained till
May, 1860, when they were withdrawn from
the territory. (See Utah.)—The priesthood
of the Mormon church is organized into the
following quorums: the first presidency, the
twelve apostles, the high council, the seventies,
high priests, elders, priests, teachers, and dea-
cons. The first presidency (in 1875) consists of
Brigham Young, George A. Smith, and
Daniel H. Wells. They preside over and direct
the affairs of the whole church. The twelve
apostles constitute a travelling presiding high
council. The whole hierarchy is divided into
two bodies, the Melchizedek priesthood and
the Aaronic priesthood. To the former, which
is the highest, belong the offices of apostle,
seventy, high priest, and elder. The
Aaronic priesthood includes the offices of bishop,
priest, teacher, and deacon, and can be
held only by "literal descendants of Aaron,"
who are designated as such by revelation.
The Mormon church teaches that there are many
gods, and that eminent saints become gods in
heaven, and rise one above another in power
and glory to infinity. Joseph Smith is now
the god of this generation. His superior god
is Jesus, whose superior god and father is
Adam. Above Adam is Jehovah, and above
Jehovah is Elohim. All of these gods have
many wives, and they all rule over their own
descendants, who are constantly increasing in
number and dominion. The glory of a saint
when he becomes a god depends in some de-
gree on the number of his wives and children,
and therefore polygamy is inculcated and wives
are "sealed" to saints here on earth to aug-
ment their power in the heavens. The gods
are in the form of men, and they are the fathers
of the souls of men in this world. The ten
commandments are considered the rule of life,
together with a revelation given to Joseph
Smith, Feb. 27, 1838, which is called "A Word
of Wisdom." It teaches that it is not good to
drink wine or strong drinks, excepting in the
sacrament of the Lord's supper, and then it
should be home-made grape wine; that it is
not good to drink hot drinks, or chew or smoke
tobacco; that strong drinks are for the wash-
ing of the body, and that tobacco is an herb
for bruises and sick cattle; that herbs and
fruits are for the food of man; that grain is
for the food of man and beasts and fowls;
and that flesh is not to be eaten by man ex-
tcepting in times of winter, cold, and famine.
This "Word of Wisdom," however, is not re-
garded precisely as a commandment, but as a
revelation to show forth the will of God, and
"suited to the condition of all saints, young
and old, male and female, without distinction."9
Infant baptism is condemned, but the children
of the saints are considered old enough at
eight years to be baptized. Baptism for the
dead is practised, a living person being publicly
baptized as the representative of one or more
deceased persons. Washington, Franklin, and
other famous men have thus been vicariously
baptized into the church. There have been
many dispensations of religious truth, begin-
ning with Adam and ending with the greatest
of all, that through Joseph Smith, which is to
culminate in the building of the New Jeru-
salem in Jackson county, Mo., and the gathering
together of all the saints on the continent of
America. A portion of the Mormons reject
polygamy, and do not approve of the political
schemes of Brigham Young and the leaders of
the church in Utah. Joseph Smith, the son
of the prophet, is regarded by them as the true
living head of the church, and under his direc-
tion they have established themselves at Nau-
vo. Their number is inconsiderable. Ano-
other branch of the church has recently estab-
lished itself at Independence, Mo., the sup-
posed site of the "New Jerusalem." (For the
political and social condition of the Mor-
mons in Utah, see Utah.)—See "The Mor-
mons," by Charles Mackay (London, 1851);

Stenhouse (New York, 1873).

MORAY, Philippe de, seigneur du Plessis-
Marly, known as Duplessis-Moray, a French
soldier, born at Buhy, Isle de France, Nov. 5,
1549, died at Forêt-sur-Sèvre, Nov. 11, 1623.
His father was a Roman Catholic, but his
mother secretly brought him up as a Pro-
estant, and after his father's death in 1560 he
openly professed that religion. At an early
age he travelled extensively, attached himself
to Admiral Coligny, and drew up a memorial in behalf of the Huguenots, which was presented to Charles IX. and Catherine de' Medici. After the massacre of St. Bartholomew's, from which he had a narrow escape, he took refuge in England. He returned in 1575, and Henry of Navarre intrusted to him some important missions to Queen Elizabeth. Being appointed general superintendent of Navarre, he stood almost alone the brunt of the religious civil war. On the alliance of his master with Henry III., he was placed in command of the town of Saumur, assigned as a place of safety to the Protestants. In 1589 he arrested and kept prisoner the old cardinal de Bourbon, whom the leaguers had proclaimed king in opposition to Henry IV. He opposed the abjuration of the latter, and evinced so intemperate a zeal for Calvinism as to incur the king's displeasure. Nevertheless he kept his governorship of Saumur, where on the death of Henry (1610) he proclaimed the authority of Maria de' Medici; but he quarrelled with that princess, and in 1620 was compelled to resign his office, receiving as indemnity a sum of 100,000 livres. His high character, virtue, and knowledge made him for nearly half a century the chief of the French Calvinists; and he was commonly styled Jean de Calvados le pape des Huguenots. He left various controversial works, and also his personal Mémoires (4 vols. 4to, 1624-52; more complete edition by Auguis, 12 vols. 8vo, 1822-25). See also Mémoires de Madame de Morny, published by Mme. de Witt under the auspices of the French historical society (2 vols., Paris, 1868-69).

MORNY, Charles Auguste Louis Joseph de, duke, a French statesman, reputed half brother of Napoleon III., born in Paris, Oct. 23, 1811, died there, March 10, 1865. He was regarded as the son of Queen Hortense and the count Auguste Charles Joseph de Flahaut. He assumed the name of the count de Morny, a French nobleman resident at the Isle de France (Mauritius), who is said to have received 800,000 francs for adopting him as a son. He was educated under the care of his supposed grandmother, Mme. de Flahaut, also known as Mme. de Souza from her second marriage with a Portuguese nobleman of that name, and placed in the institution Monur. His proficiency in study was remarkable, and he early attracted the attention of Talleyrand, who predicted that De Morny would one day be a minister. He attended one of the military schools of Paris during two years, and left it in 1839 with the rank of sub-lieutenant. He then served in Algeria, where he was wounded, and was decorated with the order of the legion of honor for saving the life of Gen. Trézel. Queen Hortense, on her death in 1837, bequeathed to him an annuity of 40,000 francs, and he soon became noted for his commercial and financial speculations. In 1888 he purchased near Clermont a manufactory for beet sugar, and largely engaged in that and other enterprises. From 1842 to 1848 he was a member of the chamber of deputies, and in 1849 he was elected to the legislative assembly. He was one of the most effective assistants of Louis Napoleon in the coup d'état of Dec. 2, 1851. After that event he held the office of minister of the interior until Jan. 23, 1852, when he relinquished it because Fould, Magne, and Rouher had withdrawn from the administration on account of the confiscation of the property of the Orleans family. Subsequently he became a member of the legislative body, and from 1854 to the time of his death was its president. He attended the coronation of the emperor Alexander II. as the representative of the French government, and was ambassador to Russia during the years 1856-7. While at St. Petersburgh he married, Feb. 19, 1857, a Russian lady of rank and wealth. In 1862 he was made duke. During the last years of his life he was actively engaged in railway, mining, and other commercial and industrial enterprises. Morny, under the pseudonym Saint-Remy, was the author of several farces and operettas.

MORO, Attilio, also called Sir Anthony More, a Flemish painter, born in Utrecht about 1520, died in Antwerp about 1580. He gained considerable reputation as a portrait painter, and in 1552 he executed likenesses of "his crown prince, the future Philip II., and of various members of the royal family of Portugal. In 1554 he painted the portrait of Philip's second wife, Mary of England, during whose reign he was court painter. Several of his portraits of the queen and of the English nobility are in the palace of Hampton court. Subsequently he was in the service of Philip II. and the duke of Alva, by the latter of whom he was appointed to the lucrative office of receiver general of the revenues of West Flanders.

MOROCCO, or Marocco (Arab. Maghreb el-Akba, "the Westernmost Place of the Barbary"), a sultanate in N. W. Africa, between lat. 27° and 36° N. and lon. 4° 30' E. and 11° 50' W., bounded N. by the Mediterranean, E. by Algeria, S. by the desert of Sahara, and W. by the Atlantic; area, about 260,000 sq. m. Its frontier on the desert is generally considered to be on a line drawn directly E. from Cape Nunn; its frontier on the province of Oran, Algeria, was determined by treaty of March 18, 1845. The coast line on the Mediterranean, about 250 m. long, runs N. W. from Algeria to Cape Tes Forcas (Ras ed-Deir), thence W. S. W. to about lon. 4° 30' W., where it again turns N. W. to Punta de Africa, its most northerly point; thence the course of the coast line is W. S. W. through the strait of Gibraltar to Cape Spartel on the Atlantic, where it turns abruptly and pursues a general S. W. course of about 750 m. to Cape Nunn. On the Mediterranean coast Spain holds several fortified convict stations: Ceuta on Punta de Africa, Peñon de Velez, Alhucemas, Melilla, and the Jafariin islands. There are several small harbors belonging to Morocco, of
which the best, that of Tetuan, at the mouth of the little river Martil, is unfit for large vessels. On the Atlantic coast, besides Tangier in the strait of Gibraltar, the principal harbors are: El-Araish (Larash), Rabat, Casablanca (Dar el-Baida), Mazagan (Jedyida), Saffi (Asfly), and Mogadore. Mazagan has a bay protected by the land against all dangerous winds, and is the only harbor on the coast possessing natural advantages which might make it a good port of the second class. The Portuguese founded an establishment here in 1506, but abandoned it in 1769. The country back of Mogadore is composed of hills of moving sand, and the place would have no existence but for the will of the sovereign. It was founded in 1760 by Sidi Mohammed, who closed Agadir, the port of Sus, once the best and most important in the empire, from fear that the inhabitants, enriched by foreign commerce, would assert their independence. There are a few smaller and unimportant ports at the mouths of rivers.—

The interior is divided into two great slopes by the Atlas mountains, which traverse it from N. E. to S. W. The chain is composed of several parallel ranges, connected with each other, and several separate lesser chains, preserving generally the same parallelism, divide the country between the main range and the Atlantic into fertile valleys and plains. On the Mediterranean coast a maritime range, called Er-Rif, from 2,500 to 3,500 ft. high, extends from Nemours in Algeria to the strait of Gibraltar; and there are also several chains running to the coast at right angles to the main range. Of the inferior chains on the southeast but little is known. The main range of the Atlas contains some of the most elevated peaks in N. Africa, many of which are covered with snow the greater part of the year. Mittizin, a peak about 30 m. S. E. of Morocco, is 11,500 ft. high. From all these mountains flow numerous streams, to which the natives give the general name of weed or wad. None of them are navigable, and many disappear in summer in the sands of the desert. Most of them change their names several times during their course. The principal rivers of the N. W. slope are the Luoco, Sebu, Burekrag, Umm er-Rebiah, and the Tensift, all of which empty into the Atlantic; those of the S. E. slope are the Moulia, which falls into the Mediterranean, the Ghir, which is lost in the desert, and the Drasa, Nun, and Sus, which empty into the Atlantic. All the rivers are rapid, and in spring and summer the larger ones cannot be forded with safety.—Little is known of the geology of Morocco, but gneiss is supposed to be the principal formation in the Atlas. Marbles of different kinds are found, one of which is as white as Carrara marble. It is probable that the celebrated Numidian marbles of the Roman writers came from the Atlas. Gold in quartz veins is also found in these mountains, and galena and in silver in the metamorphic rock in different parts of the country. Copper, iron, tin, nickel, cobalt, and antimony are abundant in Sus. At the foot of Jebel Hadjy, 15 or 16 m. N. E. of Mogadore, are numerous traces of ancient iron mines, which are supposed to have been worked by the Carthaginians. The ore found there is fine and rich. Sulphur, rock salt, and nitre are found in various places; and there are numerous mineral springs, of which the hydrogen-sulphurous springs of Mulai Yakub near Fez are said to cure cutaneous affections and scrofula.—On the great slope N. W. of the Atlas range the climate is temperate and delightful. A refreshing sea breeze prevails during the greater part of the year, and the hot winds from the desert are intercepted by the mountains. On the plain of the city of Morocco it is hot in summer, but the thermometer seldom rises above 95°, and in winter it seldom falls below 49°. The mean annual temperature is about 64°. Snow never falls there, but the winds from the glaciers of the Atlas occasionally make the nights very cold. At Mogadore the extreme fluctuation of the thermometer does not exceed 83°; the annual rainfall averages 21 inches. The year is divided into a wet and a dry season; during the former, from November to March, showers are frequent; but during the other part of the year rain seldom falls. Toward the south there is less rain; and on the S. E. side of the mountains our knowledge of the climate is very imperfect, but extremes of heat and cold are supposed to prevail, and rain to be entirely wanting.—The Atlas mountains are clothed with luxuriant forests, in which are found the live oak, the cork oak, and the oak with edible acorns; the Aleppo pine, cedar of Lebanon, spruce, locust, and juniper; the thuja, which produces sandarach, the euphorbia, and other valuable gum trees; and in Sus flourishes the argan, the seeds of whose fruit produce a valuable oil, much used by the natives. The principal fruits are the date palm, olive, orange, grape, citron, banana, fig, almond, and pomegranate; but all the other fruits of southern Europe and northern Africa, and many of those of more tropical climes, grow in perfection. Among the wild plants of the southern provinces are the caper, the archil, the dagmuz or tikvit with a juice like honey, and the femun or tailit, which also furnishes a sweet milky juice. Agriculture is in a very primitive state, and but a very small part of the arable land is cultivated. The annual production is scarcely sufficient to supply the wants of the people, and when the harvests fail famine ensues. Yet Morocco might become, under an enlightened government, one of the most productive regions of the world. Wheat, barley, maize, millet (durra), and other cereals grow to perfection, but barley is the principal grain; cotton does well, and rice and sugar cane would succeed if properly cultivated; flax, hemp, and tobacco are raised to a limited extent; and beans, peas, lentils, sesamum, saffron, canary grass, and in some parts a few turnips, are cultivated in sufficient quantities to.
supply the inhabitants. Indigo, cochineal, and silk could be raised with success, and some parts of the Atlas seem to be well adapted for coffee. — Among the wild animals of the Atlas are found hyena, jackal, and wild boar abound; and in the Sahara plains the ostrich, gazelle, and several other species of antelopes. Among the serpents are the cerastes, or horned viper, and a black snake called the buska, which is 6 or 7 ft. long and very venomous. Inoffensive serpents are numerous, and are domesticated in some places, particularly in Morocco, where they are scrupulously respected in the houses. Scorpions, lizards, and the chameleon abound, and the locust and a great variety of other insects of all colors, forms, and natures infest many parts of the country. Among the birds are the stork, flamingo, and many kinds of small game. The domestic animals are numerous, and the wealth of many of the tribes consists entirely in their flocks and herds. Horses, mules, asses, camels, cattle, sheep, and goats abound, but the pastoral art is in almost as primitive a state as agriculture. The small spirited Barbary horses are still raised, but the sultan's prerogative of taking the best for the use of his army whenever he can find them is a serious check on this industry. Their export, as well as that of horned cattle, is prohibited; but a few thousand of the latter are permitted to be shipped yearly for the use of the English garrison at Gibraltar. The sheep are much larger than the European varieties, and have broad tails loaded with fat, often weighing from 30 to 50 lbs. The wool is of fine quality and almost invariably white. The goats furnish the skins from which the celebrated morocco leather is made. Poultry abounds, and the rivers and waters of the coast are full of fish. — The inhabitants may be divided into five races. Berbers, Arabs, Moors, Jews, and Mulattoes. The Berbers, who are the aborigines, occupy the Atlas and lesser mountain ranges. They are a fine race physically, are distinguished for courage, resolution, and temperament, and make good warriors and hunters. They are more laborious and persevering than the Arabs, and follow agriculture rather than pastoral pursuits. They are the best masons in the country, and most of their houses are built of stone. The Arabs, who compose the greater part of the rural population in the plains and in the valleys near the coast, are in general the descendants of the Mohammedan invaders. They also are a fine race physically, but they are braggarts, and jealous in disposition; are incapable of supporting prosperity, and are often embroiled with the government. They live in tents, and are mostly agricultural laborers and shepherds. The Moors are a hybrid race, the greater part of them being descendants of those who were driven from Spain. They inhabit the cities and towns, and are generally effeminate, intriguing, and given to pleasure and idleness. In youth they are slender, but become very corpulent in later life. They are more polished in their manner than the Arabs, but less social. Many of them hold official positions, and a large part of the commerce is in their hands. The Jews chiefly inhabit the cities, although some are found among the Berbers, and a few even in the Sahara at Wad Nun and at Akka. They are more ignorant than their brethren in other countries, but are shrewd and enterprising, and many of them become rich, as they are the sole dealers in bullion. Most of them are engaged in commerce. The negroes are slaves or descendants of slaves imported from Soudan and other parts of central Africa. As there is no prejudice against color in Morocco, their descendants are of all shades of complexion, and most of the sheriffs and principal officials are mulattoes. Many of them become free when converted to Islamism, and are then enrolled in the bokhary or body guard of the sultan. They are intelligent and docile, but more stubborn and more malicious than the Moors and Arabs. In general the people of Morocco are barbarous and fierce, but not ferocious or bloodthirsty as they have sometimes been represented. The vendetta is customary among them, but they do not assassinate strangers and travellers. Theft is seldom accompanied by murder, except in case of prolonged resistance. Craig, a late English traveller, says the rarity of crime is remarkable. The total population has been estimated from 3,000,000 to 15,000,000. Reamnner, who visited Morocco in 1866, thinks the latter number the more probable; but according to Craig, the population, which at the beginning of the century, by a valuation considerably exaggerated, was estimated at 14,000,000, does not now exceed 4,000,000. The depopulation is still going on, and in the seaport towns alone has there been any development in the past few years. — The Mohammedan tongue is the Berber, the Arabic, and the Arak. In the south a modified form of the Berber is called Shellock. The Arabic is but a gross dialect of the language of the Koran, and the pronunciation differs in the different provinces. The Jews speak an almost unintelligible Arabic jargon, and those of Tetuan, Tangier, and El-Araish an idiom of Spanish that is almost as bad. The negroes speak the Arabic with a pronunciation peculiar to themselves; many of them preserve also their native Mandingo and Bambara tongues. The dominant religion is Mohammedanism of the Sunnite division and Malekite sect. The Berbers now generally the profession of faith of the Koran, and follow blindly the teachings of the marabouts who govern them. The negroes make sincere converts to Islamism, but are much addicted to the practice of magic. The Jews belong to the Sephardic (peninsular or western, improperly called Portuguese) division of their race, and follow the Talmud as interpreted by their rabbis to
letter. Christianity is now tolerated. Education is at a low ebb. In Fez only are there any remains of the ancient universities. Young men destined to letters, law, or the service of religion are instructed there in grammar and Arabic poetry, and in Mussulman law and theology. Elsewhere youth are taught little more than to recite passages of the Koran. The once famous libraries of Fez and Morocco have disappeared, and the empirical use of a few simples and the practice of immediate bleeding and cauterization with fire are all that remains of the medicine of Avanzoar and Averrhoes. Printing is unknown, and the architectural skill once characteristic of the race is now but a tradition.—Manufacturing industry is almost as degenerate. The most remarkable products are the beautiful and delicate tissues of wool and silk, woven by hand at Fez; the embroidery on velvet and leather; the famous morocco leather, now almost entirely superseded in Europe by the products of the Marseilles tanneries; the carpets and rugs of Rabat and Salé; arms, and silver and gold work. Most of the cities contain tanneries where morocco of different colors is produced, the red and the yellow being of particular excellence. The dyers use cochineal, rakaut, and pomegranate skins. The French introduced fuchsin, and for a time it superseded other red dyes, but its use was finally prohibited. At Fez are made and exported large numbers of the red caps which bear the name of that city. Their fine color is produced by a dye made from a berry found in the vicinity. Fez and Tetuan also manufacture bricsks, which are sent to all the cities of Morocco, but not in large numbers, for they are used only in the houses of the rich. The best arms are made in Morocco and Tetuan. Jewelry and work in silver and copper are mostly in the hands of the Jews.—The maritime commerce is wholly carried on by foreigners. No vestiges remain of the famous Barbary corsairs that once secured the Mediterranean, and Morocco now has no ship capable of making sail, and no sailor able to manage one. In 1871, 1,307 ships, of the total tonnage of 201,367, entered the eight free ports of Morocco. The entries at the several ports were as follows: Tetuan 214, Tangier 401, El-Arash 65, Rabat 54, Casablanca 165, Mazagan 224, Safiy 56, and Mogadore 95. Of these, 617 were English, 172 French, 369 Spanish, 149 Portuguese, and 14 of other nations. The total value of the exports for 1871 was $8,906,000; imports, $4,566,000. The principal exports are gout skins, wool, grain, olive oil, gum, wax, and almonds; the principal imports are Manchester goods, silver bullion, hardware, tea, and sugar. The inland traffic is inconsiderable, as there are no roads except in the vicinity of the towns, and few of the rivers have bridges; but there is a large trade with central African and Indian ports by caravans. The southern trade is carried on through Tafilet, and the caravans, which number sometimes from 15,000 to 20,000 camels, go as far as Timbuctoo, where they meet the merchants from further south and exchange products. The principal articles exported by this route are woolen cloths and haika (mantles), Turkish daggers, looking glasses, salt, and tobacco; which are bartered for ivory, gold dust, ostrich feathers, greens, malaghetta or Guinea pepper, asafoetida, incense, and slaves. The trade with the East is carried on by one large caravan yearly, which assembles at Fez about seven months before the great festival at Mecca, and occupies the intervening time in dealing with the countries through which it passes. This caravan, which is much larger than those going south, carries skins and fine leather, woolen cloths and carpets, cochineal, indigo, and ostrich feathers; and brings back Persian silks and India goods, Egyptian cotton and raw silk, spices, perfumes, &c.—The sultanate of Morocco consists nominally of the former kingdoms of Fez and Morocco, of Sus, of the oasis of Tafilet, and of several tribes S. E. of the Atlas; but while the sultan, in his spiritual character of emir of the believers, is venerated by all the Mohammedans of the west, his temporal authority extends practically only over the cities and the plains. About two thirds of the whole country, including the Atlas, a large part of Sus, and, with the exception of Tafilet, all the S. slope of the Atlas from Wad-Ghir to the ocean, ought to be considered as politically independent. The sultanate is divided into 28 provinces, in each of which are from 2 to 15 small tribes, which are subdivided in the plains into dwarfs, or movable collections of tents, and in the mountains into tehurs, or hamlets and villages in which the dwellings are permanently attached to the soil. Each province has its marabouts, sheikhs, and notables, who unite form a council. In the semi-independent provinces this is called al-arba'a, and it affects to govern according to the precepts of the Koran. In those belonging properly to the sultan each province has one or several kaid, or governors, who administer the government as they please, on condition of keeping communication safe, paying the imposts, furnishing their contingent of men and horses for the army, and sending to the sultan at each great festival as large a present of money as possible. The kaid is assisted by sheikhs chosen by themselves, who act directly upon the chiefs of dwarfs and tehurs. The cities are governed by a kaid, who is amenable to the sultan. Under him are a cadi or minister of public worship and of justice; a mouhassab or chief of police; a nadhir or keeper of the property of the mosques; and the omena or administrators of the customs and the property of the state. All the cities are enclosed by walls, and the gates are shut at night. The streets have no names, and the houses no numbers, but the division into quarters is distinct, and the inhabitants of each are held responsible as a body for the maintenance of order.
The chief interior cities, in the order of importance, are as follows: Fez, Morocco, Mqouinez, Azilal, Tanrudan, Thamez, Ujda, Alcezar el-Kebir, Wazzan, Sefroun, Dunnet, and Tafilet or Tafilet. The capitals are Fez and Morocco, in each of which the sultan resides for two or three years at a time. Mequinez is inhabited chiefly by the families of the body guard. Wazzan is the grand centre of the brotherhood of the Mulai Thaieb, and is peopled only by the descendants of the founder of this order in Algeria and Morocco. Tarudan is the capital of Sus. The army proper consists of about 30,000 cavalry, composed of the body guard and the military tribes of Fez, the Sherarda, Sherarga, Oudaya, and a part of the Gherwan, who follow from father to son the military profession (mekhaeni). The greater part of these troops always accompany the sultan; the rest are detached in companies according to need. Permanent garrisons, varying from 1,000 to 300 in number, are stationed at Fez, Marve, Rabat, Ujda, and in the Rif. In the other towns there are generally from 20 to 50 soldiers at the disposition of the authorities. The military enjoy great privileges and live at their ease. They are armed with sabres and long flint-lock guns, and wear no other distinct uniform than the Fez cap, which is worn by all state officials. The late sultan Sidi Mohammed tried to form an infantry corps, but the discipline was not compatible with the character and habits of the people, and the 3,500 or 4,000 men whom he raised were mostly renegades and foreigners. The government has mints at Fez, Morocco, and Rabat, but they do little more than convert French crowns into the money of the country. —The Mauritanian of the ancients comprised Morocco and a part of Algiers. (See Mauritania.) When the Arabs completed their conquest of northern Africa (696–709) the Moors of Morocco and Almoravides were co-extensive with the Spanish kingdoms. The national government was organized till about 877, when Edris ibn Abdallah, a descendant of Mohammed, founded the kingdom of Fez. His son and successor, Edris ibn Edris, founded the city of Fez about 807. In the 11th century the warlike sect of the Al-Murabathy or Almoravides arose among the independent tribes in the deserts of the south, and about 1058 their chief Abubekr ibn Omar was proclaimed emir of all Morocco. In 1070 he crossed the mountains, and in 1072 founded the city of Morocco. The dynasty of the Almoravides was succeeded by those of the Almohades, the Beni Merinas, and the El-Watafi. In 1561 the descendants of Sherif Hosein founded a new dynasty, which in the beginning of the 17th century had extended its sway over all Morocco and as far as Timbuctoo. In 1578 King Sebastian of Portugal invaded the country, but was defeated at Alcezar and probably killed. On the death of Hamed Sherif al-Mansour, his empire was divided among his five sons, which led to the establishment in 1648 of a new dynasty by Muley Sherif el-Fileli, king of Tafilet, which still continues. Finally, in 1770, the sultan made a treaty of peace and friendship with the United States, and in 1836 a second treaty of peace and commerce, to remain in force for 50 years. In 1814 the slavery of Christians was abolished, and in 1817 the sultan disarmed his marine and prohibited piracy. In 1844, during the reign of Abderrahman (1823–59), the Moors took up arms to aid Abd-el-Kader against the French, and the prince de Joinville bombarded Tangier and took possession of Mogadore, which was given up on the conclusion of peace. The French also bombarded Sale in 1851, in retaliation for the plunder of a ship on the coast. In 1859 the French made an incursion from Algeria into Morocco in revenge for depredations on their frontiers, and in the same year Spain declared war in retaliation for attacks on her commerce by the Rif pirates. On Feb. 6, 1860, Tetuan surrendered after a well-contested battle (Feb. 4), and in April a treaty of peace was signed, which guaranteed to Spain 400,000,000 reals for the expenses of the war. In the same year a Moroccan ambassador was sent to London, the first since the time of Charles II., and in 1861 the British government gave a guarantee for a loan of £2,000,000 to the sultan to meet his engagements with Spain. In March, April, and May, 1870, a French detachment from Algeria under Gen. Wimpffen made a tour of exploration through S. E. Morocco, and reported favorably on the climate, water, &c. In September, 1871, an insurrection of Berbers broke out in Morocco, and the Spanish fortifications at Melilla were attacked; but the guns of the besiegers were dismounted by the fire from the citadel. The sultan Sidi Mohammed, who succeeded his father Abderrahman in 1858, died Sept. 20, 1873, and his son Muley Hasan was proclaimed sultan. No general conscription existed in Morocco.

**MOROCCO** (Arab. Marakeš), a city and one of the capitals of the sultanate of Morocco, on the N. side of a plain 1,500 ft. above the sea, 4 m. S. of the river Tensift, and about 250 m. S. W. of Fez; lat. 31° 38' N., lon. 7° 36' W.; pop. about 50,000. The walls, which are 7 m. in circuit, are built of tappia (earth, pebbles, and lime pounded together), and are about 28 ft. high. One part is flanked with towers at regular intervals, but most of them are in ruins, and the walls are so dilapidated that pedestrians easily find a passage in after the gates are closed. There are seven gates, besides two leading into the kasbah or citadel. A large part of the enclosed space is covered with gardens. The streets are wide at the gates, but in the centre of the city they form a network of filthy lanes, almost impassable for pedestrians in rainy weather. The houses are generally of one story, built of tappia whitewashed, with flat roofs and terraces, and opening on an inner court. They have no windows or doors to the street, the entrance usually opening on a lane.
inhabitants of Morocco are a mixture of Moors, Algerines, Tunisians, Egyptians, Arabs from the Sahara, negroes, and Jews. The latter, who number about 6,000, have a quarter of their own, called El-Melah. They seldom go into the city proper, and when they do both men and women are obliged to take off their shoes. A large part of the business is in their hands, and they are the gold, silver, copper, and tin smiths of the city. Morocco is an agricultural rather than an industrial centre. The sole manufacture in which it excels is that of leather, particularly of red and yellow morocco. All products of the country, excepting the cereals, pay an octroi duty both going in and going out of the gates. There is also a tax of 2½ per cent. on all sales, paid by the buyer, and the government has a monopoly of tobacco.—Morocco was founded in 1072 by Abubekr ben Omar, of the dynasty of the Almoravides. It was captured and nearly destroyed in 1146 by Abdelmunen, king of the Almohades, who rebuilt and restored it in 1147–78. Schools and colleges were founded by his successors, and in the 13th century it was a famous seat of learning, and the Moors of Spain, Algeria, and Tunis sent their children to be educated in its universities. At the height of its prosperity it is said to have had a population of more than 500,000. Its decadence began with the expulsion of the Moors from Spain.

MORPHICUS (Gr. μορφεύς, to shape), in Greek mythology, the son of Sleep and god of dreams. He is represented in a reclining posture, with a crown of poppies. His name (the fashioner or moulder) was derived from his function of shaping and controlling dreams.

MORPHA. See Opium.
MORPHY, Paul Charles, an American lawyer, celebrated as a chess player, born in New Orleans, La., June 22, 1837. He early exhibited a fondness for the game of chess, and at the age of 13 had encountered successfully the best amateurs of his native city. He entered St. Joseph's college in 1850, and during his college course exhibited his remarkable skill in various contests with Löwenthal and others. At the chess congress in New York in 1857, he defeated in a majority of games, many being at considerable odds, the first players of the United States. In 1858 he first exhibited his ability to play without seeing the board, sometimes conducting seven games at once. In the summer of that year he played 14 games with Löwenthal in London, in which Morphy won 9, Löwenthal 3, and 2 were drawn. On Aug. 26 Mr. Morphy attended the annual meeting of the British chess association at Birmingham, where he played eight games simultaneously without seeing the boards, winning six games and losing one, and one being drawn. In September he went to Paris, where he first played a match of seven games with Mr. Harrwitz, winning five and drawing one; and after defeating the best French players at the café de la régence, including Rivière, Laroché, Journoud, and Devincq, he encountered on Dec. 20 the celebrated Mr. Anderssen and the champion of German chess. The result of the match was: Morphy 7, Anderssen 2, drawn 2. Mr. Morphy continued in Paris playing with his usual success till April 4, 1859, when he returned to London, and during the remainder of his stay exhibited his power in matches and in blindfold play as before. On his return to the United States he was admitted to the bar, and since then has resided and practised his profession in New Orleans, with short intervals of residence in Richmond and Mobile.

MORRIS. I. A N. county of New Jersey, bounded N. by the Passaic river, E. and S. E. by the Paterson, and marginally by the Rockaway and Whippinay rivers and the head branches of the Raritan; area, 650 sq. m.; pop. in 1870, 43,187. It is traversed by ranges of hills, some of which, as Schooley's and West Trowbridge mountains, reach a considerable elevation. It abounds in copper, iron, zinc, marble, limestone, sandstone, and manganese; there are 27 iron mines, which give employment to a great number of the inhabitants. It is intersected by the Morris canal and the Morris and Essex railroad, the latter passing through the capital. The chief productions in 1850 were 80,897 bushels of wheat, 28,776 of rye, 608,924 of Indian corn, 290,721 of oats, 49,764 of buckwheat, 168,611 of potatoes, 18,361 lbs. of wool, 535,274 of butter, and 34,859 tons of hay. There were 5,170 horses, 8,595 milch cows, 5,883 other cattle, 8,770 sheep, and 7,046 swine; 4 manufactories of brick, 13 of carriages and wagons, 1 of cotton goods, 13 of iron in various forms, 3 of machinery, 4 of paper, 1 of roofing materials, 5 of sash, doors, and blinds, 4 of woollen goods, 5 tanneries, 4 distilleries, 24 flour mills, and 15 saw mills. Capital, Morristown. II. An E. central county of Kansas, drained by the Neosho river and other streams; area, 655 sq. m.; pop. in 1870, 2,825. It is traversed by the Missouri, Kansas, and Texas railroad. The soil in parts is fertile. The W. portion is level and destitute of timber. The chief productions in 1870 were 41,714 bushels of wheat, 89,815 of Indian corn, 15,341 of oats, 17,549 of potatoes, 30,590 lbs. of butter, and 4,991 tons of hay. There were 1,033 horses, 6,606 cattle, 682 sheep, and 642 swine. Capital, Council Grove.

MORRIS, a city and the capital of Grundy co., Illinois, on the Illinois and Michigan canal, and the Chicago, Rock Island, and Pacific railroad, 58 m. S. W. of Chicago; pop. in 1870, 3,138. It is the shipping point of the county, and has an important trade in grain. It is the seat of St. Angela's academy, an institution for the superior instruction of females, under the control of the Roman Catholics, which was established in 1857. In 1873-74 it had 10 instructors and 190 students. The city has graded public schools, including a high school, two national banks, two weekly newspapers, and several churches.

MORRIS, Charles, an American naval officer, born in Newington, Conn., 1784, died in Washington, D. C., Jan. 27, 1856. He entered the navy in July, 1799, and served in the war with Tripoli, 1801-5. In January, 1807, he was promoted to a lieutenantcy, and in the war of 1812 served as first lieutenant of the frigate Constitution, distinguishing himself during the chase of that ship for three days and nights by a British squadron in July, 1812, and by his gallantry in the action between the Constitution and Guerriero on Aug. 19, in which he received a severe wound. He was made captain, and in 1814 appointed to the command of the Adams of 28 guns, in which he made an unsuccessful attempt to destroy the United States and Ireland, harassing British commerce. In August, 1814, Capt. Morris entered the Penobscot river, and running up to Hampden made preparations to heave out for repairs. While he was engaged in this, a strong British expedition entered the river to capture the ship. A militia force assembled for her protection gave way, and Capt. Morris destroyed her, directing his crew to break up into small parties and make their way for 200 m. across the thinly inhabited country to Portland. After the peace with England he continued in active employment, being off duty but about 24 years in a professional career of 56. At the time of his death he was chief of the bureau of ordnance and hydrography.

MORRIS, George P., an American journalist, born in Philadelphia, Oct. 10, 1802, died in New York, July 6, 1864. At an early age he removed to New York, where he wrote for the "New York Gazette" and the "American," to the first of which he contributed
verses as early as his 15th year. In August, 1823, in conjunction with Samuel Woodworth, he established the "New York Mirror," in which N. P. Willis and Theodore Fay were afterward associated, and which was discontinued Dec. 31, 1842. In 1843 Morris and Willis commenced the publication of the "New Mirror," which extended to three volumes, and in 1844 of the "Evening Mirror," a daily paper. At the close of 1845 he established alone a weekly journal called the "National Press," the title of which was changed to that of the "Home Journal" in November, 1846, when Willis again joined him. He acquired his chief reputation as a song-writer, and his "Woodman, spare that Tree," "We were Boys together," "Land-Ho!" "Long Time Ago," "The Origin of Yankee Doodle," "My Mother's Bible," "Whip-poor-Will," &c., became very popular. Various editions of his poems have been published. In 1887 he produced a drama entitled "Briercliff," which had a run of 40 nights, and in 1842 he wrote the libretto of an opera entitled "The Maid of Saxony." He also published a volume of prose sketches entitled "The Little Frenchman and his Water Lots" (1838). He was long a general of militia.

MORRIS, Gouverneur, an American statesman, born at Morrisania, Westchester co., N. Y., Jan. 31, 1793, died there, Nov. 6, 1816. He graduated at King's (now Columbia) college in 1768, and in 1771 was admitted to the bar. At the age of 18 he wrote a series of newspaper articles on finance, which attracted much attention. From 1775 to 1778 he was a delegate to the provincial congress of New York, in which he was a member of the committee for drafting a constitution for the state. In 1777 he was a delegate to the continental congress in 1777, and passed the following winter at Valley Forge as one of a committee appointed to examine, with Washington, into the state of the army. In 1779 he published a pamphlet entitled "Observations on the American Revolution." In May, 1780, he was thrown from his carriage, and his leg was injured so as to require amputation. In July, 1781, he was chosen by Robert Morris as assistant superintendant of finance, which office he held for 3½ years. After the revolution he resumed the practice of law, and also engaged with Robert Morris in mercantile speculations. On the death of his mother in 1786, he purchased the patrimonial estate at Morrisania from his brother. In 1787 he published an address to the assembly of Pennsylvania against the abolition of the bank of North America. He was a delegate from Pennsylvania to the constitutional convention of 1787, and was one of the committee of five appointed to draft the constitution. Mr. Morris sailed for France on business in the fall of 1788, and while there kept a minute diary. In 1791 he was appointed by Washington secret agent to England, to settle unfilled terms of the old treaty; he remained in London till September, but effected nothing. In 1792 he was appointed minister plenipotentiary to France, and served until October, 1794, when he was recalled at the request of the French government, and travelled in Europe until the autumn of 1798. In 1800 he was elected by the legislature of New York to fill a vacancy in the United States senate, and served in that body till 1803, acting with the federalists. He spent the latter years of his life in retirement. He was a fine orator, and delivered numerous public addresses. He was one of the earliest promoters of the project for constructing the Erie canal, was chairman of the canal commissioners from their first appointment in March, 1810, until near the end of his life, and in the summer of 1810 examined the route to Lake Erie. Morris's resemblance to Washington was so close that he stood as the model for the sculptor Houdon. His life, with selections from his correspondence and papers, has been written by Jared Sparks (3 vols. 8vo, 1832).

MORRIS, Lewis, a signer of the Declaration of Independence, half brother of the preceding, born at Morrisania, Westchester co., N. Y., in 1728, died there, Jan. 22, 1798. He graduated at Yale college in 1746, and engaged in farming on a very extensive scale on his paternal estate at Morrisania. He took strong ground against the act of parliament compelling the inhabitants of the province of New York to furnish with supplies the foreign troops quartered upon them. He was elected to the congress of 1775, and was a member of the committee on munitions of war. After the close of the session he was sent west to detach the Indians from the British. In 1776 he resumed his seat in congress, and signed the Declaration of Independence, although his estate was at that time in the hands of the enemy. As a consequence his manor was laid waste, and his family expelled. He afterward served in the state legislature.

MORRIS, Robert, an American financier, and a signer of the Declaration of Independence, born in Lancashire, England, Jan. 20, 1734, died in Philadelphia, May 8, 1806. When 13 years old he came to America, was placed in the counting house of Charles Willing, a merchant in Philadelphia, and in 1754 entered into partnership with the son of his employer. The firm continued till 1793, and at the beginning of the revolution was the largest commercial house in Philadelphia. Mr. Morris opposed the stamp act, signed the non-importation agreement of 1765, and was elected a delegate to the congress of 1775, serving on the military and naval committees. On July 1, 1776, he voted against the Declaration of Independence, and on the 4th declined to vote at all, considering the time premature and inappropriate; but when it was adopted he signed it. He was re-elected to congress July 29, and again in 1777. At this period he was largely employed in managing the fiscal affairs of the country; and on his personal responsibility he
frequently borrowed large sums for the use of the government. In 1789 Mr. Morris, in conjunction with other citizens of Philadelphia, established a bank, by means of which 3,000,-
000 rations of provisions and 300 hogsheads of
rum were forwarded to the army. On Feb. 20,
1781, he was unanimously elected superintendent
of finance, and by subsequent resolutions of
congress was invested with almost the entire
control of the financial affairs of the govern-
ment. At this time the treasury was more than
$2,500,000 in debt, the army was destitute, and
the credit of the country exhausted. He es-

established the bank of North America, which
was incorporated by congress Dec. 31, 1781,
and went into operation Jan. 7, 1782, with a
capital of $460,000. Pennsylvania and several
other states soon afterward passed laws to pro-
tect and facilitate its operations; and it proved
very efficient in relieving the government of
its embarrassments. In the beginning of 1781
he furnished the army with several thousand
barrels of flour; and in the campaign of that
year he supplied nearly everything required for
the expedition against Cornwallis. For this
purpose he issued his own notes to the amount
of $1,400,000, which were finally all paid. But,
harassed by the claims of the public creditors,
and indignant at the disposition of the se-
veral states to fulfil their engagements, Mr. Mor-
ris resigned in January 1783, but consented to
serve under the public gives, and did not resign
until November, 1784. On May 6, 1784, con-
gress at his urgent request appointed three
commissioners to superintend the treasury, and
a committee to inspect the conduct of the de-
partment. He published a long and able ac-
count of his administration. Before he resigned
he issued a public notice pleading himself per-
sonally to provide for his engagements in behalf
of the government. No agent of marine being
appointed, Mr. Morris, as superintendent of
finance, was compelled to regulate the affairs
of the navy until the close of 1784. He aided
in obtaining the renewal of the charter of the
bank of North America in 1786, which had
been annulled by the Pennsylvania legislature
in 1784. In 1787 he was a member of the con-
vention which framed the federal constitution;
and on Oct. 1, 1788, he was elected a member of
the first United States senate. He declined
the post of secretary of the treasury offered
to him by Washington, and recommended
Alexander Hamilton as a suitable incumbent.
In partnership with Gouverneur Morris, in the
spring of 1784, he sent to Canton the first
American vessel that ever appeared in that
port. In his old age he lost his fortune by
land speculation, and during the latter years
of his life was confined in prison for debt.
Mr. Morris was an impressive public speaker
and an able writer.

MORRIS, Thomas A., an American bishop, born in
Kanawha co., Va., April 28, 1794, died in
Springfield, O., Sept. 2, 1874. He was licensed
as a preacher of the Methodist Episcopal
church in 1814, and joined the Ohio conference
in 1816. He labored in the itinerant ministry in
Ohio, Kentucky, and Tennessee till 1834,
when he was elected first editor of the "West-
ern Christian Advocate" at Cincinnati. In
1836 he was elected bishop. For several years
previous to his death, through physical in-
firmity, he was debarred from active duty. He
published "Sermons," and "Sketches of West-
ern Methodism" (Cincinnati, 1852).

MORRIS, William, an English poet, born near
London in 1834. He is the eldest son of a
merchant who died in 1844, leaving a large
estate. He was educated at Forest school in
Wiltshamstow, at Marlborough, and at Exeter
college, Oxford. He studied painting, but did
not succeed in that profession. In 1858 he
published a small volume entitled "The De-
finite of Gibbons, and other Poems." In
1863, with several partners, he set up in Lon-
don an establishment for the artistic design-
and manufacture of various articles, especially
wall paper, stained glass, tiles, and household
decorations. At this business Morris has ever
since wrought as a designer, giving his even-
ings to the composition of poetry. He pub-
lished "The Life and Death of Jason," a nar-
native poem, in 1867, and "The Earthly Para-
dise" (4 parts) in 1865—71. The latter poem
is made up of 24 legendary and romantic tales
in verse, recited by a company of voyagers
who had sailed westward in search of a way to find
the earthly paradise. He has also published
a poem entitled "Love is Enough, or the Freeing
of Pharamond" (1873), and, in connection with
Eirikr Magnusson, "The Story of the Volsungs
and the Niblungs," translated from the Eddas.

MORRIS DANCE, an old English dance, usually
performed with castanets, tabors, staves, or
words, by young men lightly dressed, with
bells fixed about their legs, and parti-colored
ribbons streaming from their arms and shoul-
ders. It is supposed to be derived from the
Morisco or Moorish dance still popular in Spain
under the title of the fandango. In this dance
was traced as early as the reign of Henry VII.,
when it was one of the sports of May day,
Holy Thursday, the Whitson ales, weddings,
and other festivals. In the May game it was
often performed by persons representing Robin
Hood, Little John, Friar Tuck, Maid Marian,
the fool, Tom the piper, and the hobby-horse.
The May festivities of Robin Hood were chief-
ly designed for the encouragement of archery,
and it is not certain that either he or his com-
panions were prominent in the dance. Maid
Marian is supposed to represent his mistress,
but the part was often filled by a boy dressed
in a girl's habit and called queen of the May.
It was once usual for the queen to be splendidly
attired, but after the degeneracy of the dance
the character was personated by a clown, who
obtained the name of Malkin. Friar Tuck
maintained his place in the sport till the reign
of Elizabeth. The fool bore a bauble in his
hand, and a coxcomb hood with asses' ears on
his head. Tom the piper was a minstrel of the superior order, with a complicated red, blue, and yellow dress, a sword, a feather in his cap, and a tabor, tabor stick, and pipe to distinguish his profession. The hobby-horse was designed for antics and tricks of legerdemain. During the reign of Elizabeth the Puritans checked the May pastimes by their invectives against "the terrestrial furies" which indulged in them. Maid Marian and the hobby-horse were restored by King James's "Book of Sports," but were again degraded during the commonwealth. In some parts of England, however, the dance continued till very recently, and it existed in France in the 18th century.—The fullest account of the subject is by Donne, in a dissertation with his "Illustrations of Shakespeare."

MORRISON, a central county of Minnesota, intersected by the Mississippi River, and watered by several small streams; area, about 1,175 sq. m.; pop. in 1870, 6,081. The surface consists chiefly of rolling prairies; the soil is productive. The chief productions in 1870 were 11,927 bushels of wheat, 9,345 of Indian corn, 18,987 of oats, 12,668 of potatoes, and 20,006 lbs. of butter. The value of live stock was $66,116. Capital, Little Falls.

MORRISON, Robert, an English missionary, born in Morpeth, Northumberland, Jan. 5, 1792, died in Canton, Aug. 1, 1834. He was apprenticed to his father as a last maker, but commenced the study of theology in 1801, and entered the Independent academy at Hoxton in 1803. In 1804 he offered his services to the London missionary society, and in 1805 removed to the mission college at Gosport, where he began the study of Chinese. In the winter of 1807 he was ordained, and in the following autumn went to Canton, being the first Protestant missionary to China. In 1808 he was appointed translator to the East India company's factory at Canton, and began translating the Scriptures into Chinese. The New Testament appeared in 1814, and the Old Testament, executed with the assistance of Mr. Milne, in 1818. In November of the latter year Mr. Morrison caused the foundation of an Anglo-Chinese college at Malacca. In 1823-6 he was in England, and became a member of the royal society. His Chinese grammar (4to, Scampore, 1815) and his Chinese dictionary (5 vols., Macao, 1813-23) were his chief original works. His "Memos" were compiled by his widow (2 vols., London, 1839).

MORRISTOWN, a post village in Morris township, capital of Morris co., New Jersey, on the Whippany river and the Morris and Essex division of the Delaware, Lackawanna, and Western railroad, 43 m. N. E. of Trenton, and 32 m. by rail W. by N. of New York; pop. about 5,000. It is built on an elevated plain commanding beautiful views of the surrounding country. The streets are regularly laid out, the houses neatly built, and there is a public square in the centre, in which is a soldiers' monument. It is the principal market for the surrounding country, which is rich in agricultural products, and it contains a handsome court house, two national banks, manufactures of iron, &c., six hotels, five schools, three weekly newspapers, and eight churches. It is a favorite summer residence for citizens of New York. Morristown is noted as having been the headquarters of the American army on two occasions during the revolutionary war, in the winters of 1776-7 and 1779-80. The remains of an old fort are still visible in the rear of the court house. The house occupied by Gen. Washington is now the property of the state. About 3 m.
of the building is 1,248 ft., and the depth, from the front of the main centre to the rear of the extreme wing, 542 ft. The wings on the right and left of the centre building are three stories high, except those at the extreme ends, which are two stories. It is built principally of light granite quarried on the grounds, in ornamental style, and will accommodate about 1,000 patients.

MORROW, a central county of Ohio, drained by the head streams of Vernon and Olentangy or Whetstone rivers; area, 370 sq. m.; pop. in 1870, 18,588. The surface is undulating and the soil highly fertile. It is intersected by the Cleveland, Columbus, Cincinnati, and Indianapolis railroad. A large quarry of freestone is worked near the capital. The chief productions in 1870 were 207,714 bushels of wheat, 615,679 of Indian corn, 343,300 of oats, 92,459 of potatoes, 20,589 of flax seed, 31,242 lbs. of flax, 67,077 of maple sugar, 532,346 of wool, 652,684 of butter, and 88,106 tons of hay. There were 7,995 horses, 16,640 cattle, 118,291 sheep, and 16,820 swine; 7 manufactories of carriages and wagons, 1 of dressed flax, 1 woollen factory, 3 flour mills, and 14 saw mills. Capital, Mount Gilead.

MORROW, Jeremiah, an American statesman, born in Gettysburg, Pa., Oct. 8, 1771, died in Warren co., Ohio, March 22, 1852. In 1795 he removed to the Northwest territory, and in 1802 was elected a delegate to the convention for forming the state constitution of Ohio. He was the first representative in congress from that state, serving from 1803 to 1813, and was United States senator from 1813 to 1819. From 1822 to 1826 he was governor, then canal commissioner, and from 1841 to 1845 was again a member of congress.

MORSE. See Wales.

MORSE, Edward S., an American naturalist, born in Portland, Me., June 15, 1838. He prepared himself for a mechanical engineer, and spent several years as a draughtsman in the Portland locomotive works, during which time he studied zoology. In 1859 he became connected with the museum of natural history at Cambridge under Agassiz, and in 1867 with the Boston society of natural history as curator of mollusca; and he was one of the first officers of the Peabody academy at Salem, where he has long resided. In 1868 he was made a fellow of the American academy of arts and sciences, and in 1871 received the degree of Ph. D. from Bowdoin college, where until 1873 he was professor of comparative anatomy and zoology. In 1873 he was elected lecturer on zoology at Harvard college. Prof. Morse has been very successful as a public lecturer on natural history. His principal papers have been on the "Terrestrial Pulmonifer of Maine," "A Classification of Mollusca, based on the Principle of Cephalization," "On the Land Slides in the Vicinity of Portland, Me.," "On the Tarsus and Carpus of Birds," "On the Systematic Position of the Brachiopods," and "On the Embryology of Terebratulina," which have appeared in the publications of the Boston society of natural history, the Portland society of natural history, the Essex institute at Salem, and the New York lyceum of natural history. He has endeavored to show that the relations of the brachiopoda are with the che- topod worms, and not with the mollusca, where they have heretofore been placed.

MORSE, Jedidiah, an American geographer, born in Woodstock, Conn., Aug. 23, 1761, died in New Haven, June 9, 1826. He graduated at Yale college in 1783, was licensed to preach in 1785, in 1786 was tutor in Yale college, and in 1789 was installed as pastor of the first Congregational church in Charles- town, Mass. In 1794 he received the honorary degree of D. D. from the university of Edin- burgh. He prepared in 1784, at New Haven, a small 18mo geography, which was the first work of the kind published in America. This was followed by larger geographies and gazetteers of the United States from materials obtained by travelling and correspondence. Jeremy Belknap, the historian of New Hamp- shire, Thomas Hutchins, geographer general of the United States, Ebenezer Hazard, and others, who had undertaken a similar task, consented to let him use the materials they had gathered; and for 30 years he remained without an important competitor in this department. Reprints of the early editions of his larger geographical works were published in Great Britain, and French and German transla- tions in Paris and Hamburg. Much of Dr. Morse's life was spent in religious controversy, in maintaining the orthodox faith in the New England churches against Unitarianism. He engaged actively in 1804 in the enlargement of the Massachusetts general association of Congregational ministers; in 1805 he established the "Panoplist," a monthly religious periodical, which he was engaged in, and had in five years; he was prominent in founding the Andover theological seminary, and in effecting the union between the Hopkinsians and other Calvinists on their common symbol, the assembly's catechism, the articles of which union were signed in his own study in Charles- town, in the night of Nov. 30, 1807, by himself, Dr. Samuel Spring, and Dr. Eliphalet Pearson; and he participated in the organization of the Park street church in Boston in 1808. His persevering opposition to the so-called "liberal" views of religion brought on him a persecution which deeply affected his naturally delicate health; and in 1820 he re- signed his pastoral charge. In that year he was commissioned by the government to visit the Indian tribes on our N. W. borders; and the record of his labors was published in 1822 under the title of "Indian Report," &c. Dr. Morse also published "A Compendious His- tory of New England," in conjunction with Elijah Parish, D. D. (Cambridge, 1804; 3d ed. enlarged, 1820); "Annals of the American
Revolution" (Hartford, 1824); and 25 sermons and addresses on special occasions. His life has been written by the Rev. William B. Sprague, D. D. (New York, 1874). H. Samuel Finley Breese, an American artist and inventor, eldest son of the preceding, born in Charlestown, Mass., April 27, 1791, died in New York, April 2, 1872. He graduated at Yale college in 1810, and went to England with Washington Allston in 1811 to study painting under his tuition and that of Benjamin West. In 1813 he received the gold medal of the Adelphi society of arts for an original model of a "Dying Hercules," his first attempt at sculpture. He returned to the United States in 1815, practised his profession in Boston and in Charleston, S. C., and removed to New York in 1822. In 1824-5, in connection with other artists, he organized a drawing association, which resulted in the establishment in 1826 of the "National Academy of Design." Morse was chosen its first president, and was continued in that office for 16 years. In 1829 he visited Europe a second time to complete his studies in art, residing for more than three years in the principal cities of the continent. During his absence abroad he was elected professor of the literature of the arts of design in the university of the city of New York; and in 1835 he delivered a course of lectures before that institution on the affinities of those arts. While in college Mr. Morse had paid special attention to chemistry and natural philosophy; and these sciences at length became a dominant pursuit with him. In 1826-7 Prof. J. Freeman Dana had been a colleague lecturer in the city of New York with Mr. Morse at the Athenæum, the former lecturing upon electro-magnetism and the latter upon the fine arts. They were intimate friends, and in their conversations the subject of electro-magnetism was made familiar to the mind of Morse. The electro-magnet on Sturgeon’s principle (the first ever shown in the United States) was exhibited and explained in Dana’s lectures, and at a later date, by gift of Prof. Torrey, came into Morse’s possession. Dana even then suggested by his spiral volute coil the electro-magnet of the present day; this was the magnet in use when Morse returned from Europe, and it is now used in every Morse telegraph throughout both hemispheres. He embarked in the autumn of 1832 at Havre on board the packet ship Sully; and in a casual conversation with some of the passengers on the then recent discovery in France of the means of obtaining the electric spark from the magnet, showing the identity or relation of electricity and magnetism, Morse’s mind conceived not merely the idea of an electric telegraph, but of an electro-magnetic and chemical telegraph of a grand telegraphic character, substantial and essentially as it now exists. The testimony to the paternity of the idea in Morse’s mind and to his acts and drawings on board the ship is ample. His own testimony is corroborated by all the passengers (with a single exception) who testified with him before the courts, and was considered conclusive by the judges; and the year 1832 is therefore fixed as the date of Morse’s conception, and realization also, so far as drawings could embody the conception, of the telegraph system which now bears his name. (See Jackson, Charles Thomas.) A part of the apparatus was constructed in New York before the close of 1832, but circumstances prevented its completion before 1835, when he put up a half mile of wire in coils around a room and exhibited a telegraph in operation. In September, 1837, he exhibited the operation of his system in the university of New York. From the greater publicity of this exhibition, the date of Morse’s invention has erroneously been fixed in the autumn of 1837, whereas he operated successfully with the first single instrument in November, 1835. In 1837 he filed his caveat in the patent office in Washington, and asked congress for aid to build an experimental line from that city to Baltimore. The house committee on commerce gave a favorable report, but the session closed without action, and Morse went to Europe in hope of interesting foreign governments in his invention. The result was a refusal to grant him letters patent in England, and the obtaining of a useless brevet d’invention in France, and no exclusive privilege in any other country. He returned home to struggle again with scanty means for four years, during which he continued his appeals at Washington. His hope had expired on the last evening of the session of 1842-3; but in the morning, March 4, he was startled with the announcement that the desired aid of congress had been obtained in the midnight hour of the expiring session, and $20,000 placed at his disposal for his experimental line between Wash-ington and Baltimore. In 1844 the work was completed, and demonstrated to the world the practicality and the utility of the Morse system of electro-magnetic telegraphs. (See Telegraph.) Violations of his patents and the assumption of his rights by rival companies involved him in a long series of lawsuits; but these were eventually decided in his favor, and he reaped the benefits to which his invention entitled him. It is doubtful if any American ever before received so many marks of distinction. In 1846 Yale college conferred on him the degree of LL. D.; and in 1848 he received the decoration of the Nishan Ittikar in diamonds from the sultan of Turkey. Gold medals of scientific merit were awarded him by the king of Prussia, the king of Wartemberg, and the emperor of Austria. In 1856 he received from the emperor of the French the cross of chevalier of the legion of honor; in 1857 from the king of Denmark the cross of knight commander of the first class of the Dannebrog; in 1858 from the queen of Spain the cross of knight commander of the order of Isabella the Catholic; from the king of Italy the cross of the order of SS. Maurice and Lazarus, and from
the king of Portugal the cross of the order of the tower and sword. In 1856 the telegraph companies of Great Britain gave him a banquet in London; and in Paris, in 1858, another banquet was given him by Americans, numbering more than 100, and representing almost every state in the Union. In the latter year, at the instance of Napoleon III., representatives of France, Russia, Sweden, Belgium, Holland, Austria, Sardinia, Tuscany, the Holy See, and Turkey met in Paris to decide upon a collective testimonial to him, and the result was a vote of 400,000 francs as a personal reward for his labors. On Dec. 29, 1868, the citizens of New York gave him a public dinner. In June, 1871, a bronze statue of him, erected by the voluntary contributions of telegraph employees, was formally unveiled in the Central park, New York, by William Cullen Bryant; and in the evening a reception was held in the academy of music, at which Prof. Morse telegraphed, by means of one of the instruments used on the original line between New York and Washington, a message of greeting to all the cities of the continent. The last public service which he performed was the unveiling of the statue of Franklin in Printing House square, New York, on Jan. 17, 1872. Submarine telegraphy also originated with Prof. Morse, who laid the first submarine lines in New York harbor in the autumn of 1842, and received at the time from the American institute a gold medal for that achievement. In a letter from Mr. Morse to the secretary of the United States treasury, dated Aug. 10, 1843, it is believed occurs the first suggestion of the project of the Atlantic telegraph. While in Paris in 1839 he made the acquaintance of Daguerre, and from drawings furnished him by the latter he constructed on his return the first daguerreotype apparatus and took the first sun pictures ever taken in America. He was the author of various scientific and literary papers. In 1829 he published a collection of the poems of Lucretia Maria Davidson, with a memoir; and in 1835 a volume entitled "Foreign Correspondence and Reminiscences of the Liberties of the United States." A series of papers of reminiscences of his early struggles in behalf of the telegraph appeared in 1868. His life has been written by the Rev. S. Irenaeus Prime, D. D. (New York, 1875).

III. Sidney Edwards, an American journalist and geographer, brother of the preceding, born in Charlestown, Mass., Feb. 7, 1794, died in New York, Dec. 23, 1871. He graduated at Yale college in 1811. In 1812-15 he wrote a series of articles for the Boston "Columbian Centinel," illustrating the danger to the American Union from an undue multiplication of new states in the south, and showing that it would give to a sectional minority the control of the government. In 1815, while studying at the law school in Litchfield, Conn., he was invited to establish a weekly newspaper in Boston, which resulted in the issue of the "Boston Recorder," the prototype of that class of journals now so widely known as "religious newspapers." He was the sole editor and proprietor during the 15 months in which he was connected with it. In 1817 Mr. Morse, in connection with his elder brother, invented and patented the flexible plated paper. In 1818 he published a 12mo school geography, and in 1822 an 8vo geography, which was used as a text book in several American colleges. In May, 1823, in connection with his younger brother Richard C. Morse, he established the "New York Observer," now the oldest weekly newspaper in that city, and the oldest religious newspaper in the state of New York. In 1834 he conceived the idea of a new mode of engraving, applicable especially to the production of plates for printing maps in connection with type under the common printing press; and after five years of experiment he succeeded in June, 1839, with the aid of his assistant, Henry A. Munson, in producing by the new art, which he named cerography, superior map prints. One of the first applications of cerography was to the illustration of a school geography written by the inventor, of which more than 100,000 copies were printed and disposed of during the first year. The art of cerography has never been patented, nor has the process been revealed to the public. Mr. Morse continued as senior editor and proprietor of the "Observer" till 1858, when he disposed of his interest to the Rev. S. I. Prime, his associate since 1836. The last years of his life were devoted to the invention of the bathometer for rapid exploration of the depths of the sea, and he was engaged in an essay on the subject at the time of his death.

MORTAR. See ARTILLERY, and CANNON.

MORTGAGE (Fr. mort, death, and gage, pledge; Lat. solum mortuum). Kent defines a mortgage to be "the conveyance of an estate by way of pledge for the security of a debt, to become void on payment of it." The old law writers Glanvil and Spelman say that mortgage is so called because, between the time of making the mortgage, the property is still in the possession of the debtor. For payment of the debt, the creditor by the old law received the rents of the estate to his own use, so that these rents were dead or lost to the mortgagee. Littleton gives another derivation of the word, viz.: "If the feoffor doth not pay the sum due at the day limited, then the land which is put in pledge upon condition for the payment of the money is taken from him, and so dead to him upon condition." This derivation is the one usually adopted; though the former has been sometimes preferred, not only because the idea which it conveys of the mortgage, or solum mortuum, is directly opposed to that of the solum vivum, an old form of security no longer in use, in which the accruing rents were applied to diminish the debt, but also because it illustrates the intention which mortgages were first probably designed to effect. For in the times when the exaction of interest was esteemed
MORTGAGE

Usurious and was prohibited by the law, this conditional alienation was devised, not at all with the design of depriving the mortgagee of his property if he failed to repay the money, but that the mortgagee might in the mean time receive the rents to his own use in lieu of what he would otherwise have received as interest. — A mortgage was generally created by a conveyance of lands from a debtor to his creditor, with a condition that if a sum of money were paid on a certain day the conveyance should be void, and the debtor might have his former estate. But a mortgage might also be made by an absolute deed of conveyance and a defeasance back to the grantor. This defeasance was a separate instrument defeating the principal deed by making it void if the condition was performed. The former mode was by far the most usual. The maxims of the common law were strictly applied to this kind of conveyance; and if the money were not paid at the very day specified in the deed, the lands were absolutely forfeited, nor would a subsequent tender of the money avail the debtor. But the mortgaged lands were plainly only intended as security for the payment of the money borrowed; and large estates were sometimes pledged for the payment of small debts. A strict forfeiture in such cases was not only inconsistent with the plain principles of justice, but was contrary to the spirit of the contract. For these reasons the court of chancery interposed, and by an equitable construction mitigated the severity of the common law, by holding the condition to be in the nature of a penalty, against which a just relief should be given. This just relief consisted in allowing the debtor, if within a reasonable time he paid the debt with interest, to call on his creditor for a reconveyance of the lands. But on the other hand, chancery gave to the mortgagee, after reasonable indulgence to the mortgagee, the right to call upon the latter for the payment of the debt, or in default thereof to be for ever foreclosed or excluded from any further right of redemption. The right of redemption is considered in equity to be an inseparable incident of every mortgage, and no executory agreement that it shall be forfeited, lost, or abridged on failure to perform the condition of the mortgage will be sanctioned. From mortgages, however, in respect to restrictions of the equity of redemption, must be distinguished sales with agreements to repurchase, or, as they are usually termed, conditional sales. In their forms the two transactions are often very similar, and it is difficult to distinguish them. The difference is, that one is only security for a debt, while the other is a regular purchase, for a price paid or to be paid, to become absolute on a particular event. Since this complete recognition of the equity of redemption by the courts, the mortgage has gradually ceased to be looked upon as a conveyance of an estate; and though it still is so in form, the mortgagee is regarded as owner subject to a lien on the land for the amount of the mortgage debt, and he may sell or mortgage again subject to such lien; the land may be taken on execution against him; it is subject to dower and curtesy, and on his death passes to his heirs. On the other hand, the interest of the mortgagee is personality, and may be sold as such, and the mortgage lien passes on a sale of the debt whether formally assigned or not. One important incident usually pertaining to ownership, however, still attaches to the mortgagee's right; namely, that he may demand and obtain possession even before his debt is due. This right, however, is taken away by statute in some of the United States. The lien of the mortgagee is terminated by payment, without any formal discharge, though an instrument to go upon the record of the mortgage as evidence of the fact is usually required and given. A tender of the amount will also discharge the lien, even though not accepted. — The equity of redemption can only be cut off by some species of foreclosure. Possession of the mortgagee may ripen into foreclosure, if he occupies the land for a period after the debt is due equal to the time required at law to bar a right to lands under the statute of limitations, and in some states for a much shorter period after formal entry as provided. If the mortgage, as is usually the case, contains an authority to the mortgagee to sell the land to satisfy the debt, he may foreclose by the exercise of this power at public auction, without resort to suit. Statutes regulate the process, and usually require a previous published notice for several weeks or months. The most usual process of foreclosure is by suit in equity, or analogous proceedings, in which decree or judgment will be entered that unless payment be made by a short day named, the land shall be sold by the proper officer of the court for its satisfaction. Sometimes the judgment declares, a decree for strict foreclosure is made; that is, it is decreed that unless payment is made by the day fixed the equity of redemption shall be barred, and the title of the mortgagee be established. Usually the mortgage secures the personal obligation of the mortgagee, evidenced by bond, note, or other form of promise; but sometimes it is given without, the mortgagee simply conveying the land with a condition that the conveyance shall be void if a certain sum shall be paid at a certain time named. Such a mortgage leaves it to his option to pay or not, and the mortgagee's remedy is confined to the land if he fails to pay. But when a mortgage is given to secure a personal obligation, the mortgagee will pursue his remedy by suit on such obligation or by foreclosure, as he may prefer; and if he elects the latter process and fails to realize sufficient to satisfy the debt, he may then resort to the personal responsibility of the mortgagee for the deficiency. It should be added that mortgages may be conditioned for the performance of any other legal
promise besides the payment of money; but the rules above given are equally applicable to all cases.—Something may here be said of equitable liens in the nature of mortgages. In England, where the borrower of money deposits with the lender the title deeds of an estate, he having no interest therein, to the security of the loan, and this is called an equitable mortgage, because the courts of equity take notice of and enforce it, though it is not recognized at law. This principle is unknown in the law of the United States. But the similar lien of the vendor of lands for unpaid purchase money is recognized both here and in England. (See Lien.)—Many of the rules applicable to mortgages of real property are involved also in those of personal property, but the difference in the subjects introduces some differences into the law. Any personal property, and any profits arising out of personal chattels, may be the subjects of mortgage. But the articles must be such that they are capable of being specifically designated and identified by written description. The mortgagee has the legal title subject to be defeated by redemption, and, unless otherwise agreed, the right to the immediate possession. As between the parties, the mortgage is valid without a change of possession; but as to subsequent purchasers and creditors, the continued possession by the mortgagee is prima facie but not conclusive evidence of fraud; the burden of proof rests on the mortgagee to explain the transaction, and it is for the jury to decide upon the facts. The mortgage must be generally recorded upon a public register; but a full actual notice, such a notice, says the court in Massachusetts, as would have been given by the instrument of mortgage, may preclude a subsequent purchaser or creditor from availing himself of the omission of registration. Under the usual statutory provisions the mortgage must be recorded in the town where the mortgagee lives. In these mortgages the property passes so completely to the creditor that, unlike the equity of redemption in mortgages of real property, it cannot be seized on execution or attached as the property of a mortgagee. This rule is modified by statute in some of the states. As to assignment and extinguishment of the mortgage by payment, the same general principles apply as to mortgages of real property. The same remark may be made of the distinction between mortgages and conditional sales. The legal doctrine respecting the mortgagee's interest being strictly maintained, a failure to pay the debt at the time appointed vests in him an absolute title, unless where the statutes of the state in which the transaction took place provide an equity of redemption. In other cases, however, this right may be given by courts having equitable powers.

MORTIER, Edouard Adolphe Casimir Joseph, duke of Treviso, a French soldier, born at Cateau-Cambrésis, Feb. 13, 1768, died in Paris, July 28, 1835. He served as captain under Dumouriez in 1791, was made adjutant general for his bravery at Hondschoote in 1793, and became brigadier after the battle of Altenkirchen, June 4, 1796. In this capacity he served in 1796 on the Danube, and in Switzerland under Masséna. After the death of Bonaparte he was named commander of the 15th and 16th military districts, sent him to Hanover, which he conquered in 1803, put him at the head of the artillery of the consular guard, and in 1804 made him marshal of the empire. He led a division in the campaign against Austria in 1805; subdued Hesse-Cassel and Hamburg in 1806; worsted the Swedes in several encounters, and occupied Pomerania with the exception of Stralsund. In 1807 he assisted in the campaign against Prussia, fought at Friedland, and received the title of duke of Treviso. As commander of the 5th corps of the army in Spain, he participated in the siege of Saragossa, won a victory at Ocaña, Nov. 19, 1809, laid siege to Cadiz, and defeated the Spaniards on the Géwora in 1811. In the expedition against Russia in 1812, he commanded the junior imperial guard. He figured in nearly all the battles fought in 1813, and on March 30, 1814, with Marmont, he took part in the defence of Paris. Having adhered to the Bourbons, he was named peer of France during the first restoration, but joined Napoleon on his return from Elba. On the second restoration, his refusal to sit among the judges of Marshal Ney lost him his peerage. In 1816 he was elected to the chamber of deputies, and in 1819 was restored to his seat in the upper chamber, where he voted with the liberal party. Under Louis Philippe he was ambassador to Russia in 1831, and prime minister in 1834, with the portfolio of the war department. He was killed by Fieschi's "infernal machine," while on horseback by the side of Louis Philippe.

MORTIFICATION. See GANGRENE.

MORTIMER, Roger, baron of Wigmore, earl of March, the favorite of Isabella, queen consort of Edward II. of England, executed at Smithfield, Nov. 29, 1330. He was convicted of treason in the reign of Edward II., and pardoned, but afterward took part in the rebellion of the earl of Lancaster, and was made prisoner at Boroughbridge in 1322. His life was again spared, and having escaped from the tower, he went to France and entered the service of Charles of Valois. At Paris in 1325 he met Queen Isabella, who had been sent thither by Edward to negotiate a treaty. The queen entered into guilty relations with him, and, having secured the person of her young son, planned with Mortimer and the other leaders of the barons to secure possession of the throne of Edward III. of England in 1326. The king was deposed, and his son Edward III. was proclaimed in his stead, and for some years Isabella and her paramour governed the realm in the name of the young prince. A council of regency had been
appointed, but Mortimer superseded them all. He procured the death of the deposed monarch in his prison, and obtained the title of earl of March and valuable confiscated estates. But the scandal of his life was denounced from the pulpit; the nobles wearied of his arrogance, and Edward finally resolved to take the sceptre into his own hands. While the queen and Mortimer in 1380 were lodged in Nottingham castle during the session of parliament in that town, the king and Lord Montacute with attendants entered by night and carried off the earl. The king summoned a new parliament to meet him at Westminster, and by it on Nov. 26 Mortimer was condemned as a traitor.

MORTMAIN (Fr. mort, dead, and main, land; Lat. mortua manus). Under the system of feudal tenures, the lords of estates enjoyed certain privileges on the death or change of their vassals. When the tenant died, leaving only an infant heir, the lord resumed the fee and retained it during the heir's minority, in order to maintain out of its rents and profits a person capable of rendering the services due for the lands. This was the lord's wardship. Marriage, in the sense of the feudal law, consisted in his right to exact a price for consenting to the marriage of his ward. Reliefs was another incident of feudal tenure; it was a fine or composition paid by the heir for the privilege of succeeding to the estate, which had reverted in the lord on the death of his immediate grantor. These and similar profits accrued to the lords on the death of their feudatories. It is the distinctive quality of a corporation that it never dies, and lands held by such bodies produced none of these feudal fruits; but, in the language of Sir Edward Coke, "the lands were said to come to dead hands as to the lords." The mischief existed even before the conquest. Within two centuries after it, says Blackstone, the busy acquisition of landed estates by the ecclesiastical corporations had diminished perceptibly the feudal services ordained for the defence of the realm; the circulation of property from man to man began to stagnate, and the lords were curtailed of their wardships, reliefs, escheats, and the like fruits of their seigniories. The evil attracted the attention of the legislature, and it began to impose restraints on the capacity of corporations aggregate to acquire lands. The earliest of the laws made with this intent is contained in Magna Charta. The 36th chapter of that instrument declares that "it shall not be lawful for any one to give his lands to any religious house, and to take the same land again to hold of the same house, &c., upon pain that the gift shall be void and the land shall accrue to the lord of the fee." This act destroyed the power to take by gift; for this mode had been adopted by the ecclesiastics to evade the necessity of asking the king's license, which they must by the existing laws have done if they took the lands by purchase. The religious houses next attempted to accomplish their object by buying lands that were bona fide holden of themselves, as lords of the fee, or by taking long leases of the desired estates. This is the origin of those terms for 1,000 years or more, sometimes met with in conveyances. This evasion of forfeiture produced the statute de religiosis (7 Edward I.), which provides that "no persons, religious or otherwise, whatsoever, shall buy or sell any lands or tenements, or under the color of any gift or lease or any other title whatsoever to receive the same, or by any other craft shall appropriate lands in any wise to come into mortmain, upon pain of forfeiture, at the election of the lords of the fee." But their shrewd lawyers contrived still to relieve the clergy from the embarrassments of these acts. They observed that the statutes thus far extended only to gifts and conveyances between the parties. They invented what afterward became one of the most approved assurances in the English conveyancing, namely, a recovery; that is, conferring title to the land which was intended to be conveyed, they brought an action to recover it. By collusion with the tenant no defence was made, and it was the necessary legal consequence that the land was adjudged to the demandants. This contrivance was defeated by the statute of Westminster the second, 13 Edward I. Incapacitated now to take either by gift, purchase, lease, or recovery, and despairing of holding any legal estate in lands, the ecclesiastics resorted to the distinction, familiar to the Roman law, between the right to the rents and profits of land and the right of property in the land itself. They therefore procured a conveyance to a third person and his heirs, with the understanding that the religious houses and their successors should have the beneficial enjoyment of the estate. This usufructuary interest, as distinguished from the legal ownership, was denominated the use, and founded the whole doctrine of use and trusts in the present law. Once more the legislature interposed, and by the statute 15 Richard II. declared that no conveyance of lands or other possessions should be made to the use or profit of any spiritual persons, without the license of the king and the mesne lords, upon pain of forfeiture. Though these statutes of mortmain were generally directed against the ecclesiastical corporations, civil corporations were equally capable of the mischief, which they contemplated; indeed, they are within the letter of the acts 7 Edward I. and 15 Richard II. The effect of these statutes was to make all lands conveyed in mortmain forfeitable, if the lords or the king elected. But a waiver of this right of forfeiture was always a sufficient license to corporations to hold lands. In process of time, as the mesne seigniories declined, and the rights of intermediate lords could be hardly traced, the license of the king as lord paramount was esteemed sufficient. It was therefore provided by the statute 7 and 8 William III., c. 97, that for the future the crown might, in its discretion, grant
a license to take or alien in mortmain, of whomsoever the estates might be held. The act 9 George II. is now the leading English statute of mortmain. It forbids the gift of money or land to charitable use, except by deed operating immediately, and without power of revocation, formally executed and enrolled in chancery at least six months before the donor's death. In favor of churches, colleges, and hospitals, some modifications of the statute have been admitted.—In the United States the English mortmain laws have not in general been adopted or recognized, except in Pennsylvania; and in that state, by an act passed in 1855, bequests, devises, or conveyances for religious or charitable uses may be valid if made by deed or will at least one calendar month before the death of the testator or donor. In New York, by a statute enacted in 1848, gifts to charitable corporations by will must be made two months before the testator's death; and by another enacted in 1860 any person having a husband, wife, child, or parent is precluded from bequeathing more than one half his clear estate to any society, association, or corporation. In Georgia in like manner a gift to charitable uses by will is made void, if the testator has a wife or issue living, unless made 90 days before his death. In other states the checks to the acquisition of real estate by corporate bodies are such as are imposed by their charters, or by the statutes and laws in England under which they have become incorporated.

MORTON, a central county of Dakota, bounded E. by the Missouri river, recently formed, and not included in the census of 1870; area, about 1,100 sq. m. It is intersected by the Heart and Cannon Ball rivers. The Northern Pacific railroad is to pass through it. The surface consists chiefly of undulating prairies.

MORTON, James Douglas, earl of, regent of Scotland, born in Dulceith in 1530, executed in Edinburgh, June 8, 1581. He was a younger son of the great family of Angus, but in 1553 succeeded to the estates and title of his uncle, the third earl of Morton. In 1561 he became privy councillor, and in the beginning of 1563 was appointed lord high chancellor. He participated in the murder of Rizzio, and fled to England, but was pardoned. Although cognizant of the plot to destroy Darnley, he seems to have had no hand in its execution. After the forced abdication of Mary which followed the death of Darnley, and the coronation of her infant son, Morton was reinstated in his office of lord chancellor. He supported the interests of the earl of Murray, the regent, against those of the queen; and to him is especially due the preservation of the battle of Langside, in consequence of which Mary determined to fly to England. In the violent contentions which divided Scotland after the assassination of Murray, Morton became the real head of the Protestant party, and was a leader of that portion of the people who espoused the king's cause as opposed to the queen's. The earl of Mar, who had succeeded the earl of Lennox as regent, having died in October, 1572, Morton was elected regent in his stead on Nov. 24. Thenceforth he ruled Scotland with great rigor, thereby rendering himself odious. He resigned Sept. 13, 1577, but soon regained his authority. Through the agency of the new favorite of the king, Capt. Stewart, he was brought to trial for participation in the murder of Darnley, found guilty of high treason, and decapitated by an instrument called the maiden, which he is said to have introduced into Scotland.

MORTON, John, one of the signers of the Declaration of Independence, born in Ridley, Chester (now Delaware) co., Pa., in 1724, died in April, 1777. He was for many years a surveyor. In 1759 and for many sessions subsequently he was a member of the general assembly of Pennsylvania, serving for several sessions as speaker. He was a member of the stamp act congress, which met in New York in 1765. From 1766 to 1770 he was high sheriff of his county, and afterward became judge of the court of common pleas, and a judge of the supreme court of Pennsylvania. In 1774-6 he was a member of the continental congress, and gave the casting vote of Pennsylvania in favor of the Declaration of Independence. He was chairman of the committee of the whole on the adoption of the system of confederation.

Morton, Nathaniel, secretary of Plymouth colony, born in Mass., in 1820, died in Plymouth, June 29, 1655. He came to America with his father in July, 1623, and in 1645 was appointed secretary of the colony, which office he held until his death. He was the author of "New England's Memorial, or a Brief Relation of the most Memorable and Remarkable Passages of the Providence of God manifested to the Planters of New England," &c., compiled chiefly from the manuscripts of his uncle William Bradford and the journals of Edward Winslow, and including the period from 1620 to 1646 (4to, Cambridge, 1669; 2d ed., Booke, 1721; 3d ed., 1722; 4th ed., 1772; 5th ed., with notes by Judge Davis, 1829; 6th ed., with notes by the Congregational board, 1855). In 1680 he wrote a brief ecclesiastical history of the Plymouth church in its records.

Morton, Samuel George, an American physician, born in Philadelphia, Jan. 26, 1799, died there, May 15, 1851. He studied medicine, and graduated at the university of Pennsylvania in 1820. In the same year he entered the university of Edinburgh, where he graduated in 1823. In 1824 he settled in Philadelphia as a physician. He was recording secretary of the Philadelphia academy of natural sciences in 1827, and president in 1840. In 1834 he went to the West Indies, where he studied the diversity of races and the relations resulting from their contact. In September, 1839, he was elected professor of anatomy in the Pennsylvania medical college, which post he resigned in 1843. His collection of skulls, which was the largest museum of comparative
craniology in existence, contained about 1,500 specimens, nearly 900 of which were human, obtained from widely separated regions of the earth. It now belongs to the Philadelphia academy of natural sciences. The result of his investigations, as bearing specially on the American aborigines or Indians, is embodied in "Crania Americana, or a Comparative View of the Skulls of various Aboriginal Nations of North and South America; to which is prefixed an Essay on the Varieties of the Human Species," with 78 plates and a map (folio, Philadelphia and London, 1839). His "Crania Agyptiac a, or Observations on Egyptian Ethnography, derived from History and the Monuments," with numerous plates and illustrations (4to, 1844), was based principally on a collection of 96 heads obtained by G. R. Gliddon from the tombs and catacombs of Egypt. He also published "Observations on the Ethnology and Archeology of the American Aborigines" (Silliman's "Journal," vol. ii., 2d series, 1846); an "Essay on Hybridity in Plants and Animals, considered in reference to the question of the Unity of the Human Species" (ib., vol. iii., 1847); and "An illustrated System of Human Anatomy, Special, General, and microscopic" (1849).

Morton, William Thomas Green, an American dentist, born in Charlot, Mass., Aug. 9, 1819, died in New York, July 15, 1868. In 1840 he began the study of dentistry in Baltimore, and 18 months afterward settled in Boston. Among improvements introduced by him was a new kind of solder by which false teeth are fastened to gold plates, preventing galvanic action. In his search for means of removing the roots of old teeth without pain, he tried stimulants, even to intoxication, opium, and magnetism, but in vain. While attending lectures at the medical college in Boston in 1844, for the purpose of increasing his knowledge with reference to this object, he learned that sulphuric ether could be used with very small quantities without danger; and after experimenting on himself and becoming satisfied of its safety, he administered it to a man on Sept. 30, 1846, producing unconsciousness, during which a firmly rooted bicuspids tooth was painlessly extracted. After numerous other successful experiments, he communicated their result to Dr. J. C. Warren, and at his request administered the ether on Oct. 16, 1846, in the Massachusetts general hospital, to a man from whose jaw was removed a vascular tumor, the patient remaining unconscious during the operation. From this date the introduction into general surgery of the discovery of ethereal anaesthesia. Like other great discoveries, it met with bitter professional opposition. In order to protect himself against such opposition he obtained a patent for it, under the name of "Iletheon," in November, 1846, in the United States, and in the following month in England, offering, however, free rights to all charitable institutions in all parts of the country. Notwithstanding his generous offers, government appropriated his discovery to its use without compensation. Several claimants for the honor of the discovery soon appeared, among whom was Dr. C. T. Jackson; and when the French academy examined the testimony, some of the members at first recognized him as the discoverer; but the committee of the academy awarded the Montyon prize of 5,000 francs to be equally divided between him and Dr. Morton. The latter declined to receive this joint award, protested against the decision of the academy, and in 1853 received the larger gold medal, the Montyon prize in medicine and surgery. He had to contend with many troubles; his business was broken up, and his house was attached by the sheriff for debt; but his indomitable will and the encouragement of friends enabled him to maintain his claims. He presented his first memorial for compensation to congress in December, 1846, but the appointed committee did not report. Strengthened by the testimonial of the trustees of the Massachusetts general hospital in 1848, it concurred to him the discovery of the power and safety of ether in producing anaesthesia, he made a second application to congress in January, 1849; a committee composed of physicians reported that he was entitled to the merit of the discovery, but they did not recommend any pecuniary remuneration. In December, 1851, he made a third appeal to congress, and his memorial was referred to a select committee; the report of the majority awarded the honor of the discovery to him, and in April, 1852, a bill was reported appropriating $100,000 as a national testimonial, on condition that he should surrender his patent to the government. This bill was not acted upon directly, but having been brought before the senate as an amendment to the army appropriation bill, it was defeated. In 1853 an amendment to the appropriation bill was offered, granting $100,000 to the discoverer of practical anaesthesia; after a warm debate it passed the senate, 26 to 23, but failed in the house. In 1854 a similar bill passed the senate by 24 to 13, but was lost in the house. In the same year Morton attempted to obtain from the president a recognition of the validity of his patent, supported by the recommendation of 150 members of congress that the right to use his discovery be purchased for the public service, or that the government respect its own patent and discontinue its use; after two years delay the president informed him that whenever it was decided in the courts that the government had violated his patent, it would pay. At this defeat his creditors became impatient, and reduced him to utter poverty; but in the winter of 1856-'7 a plan for a national testimonial was instituted in Boston, and an appeal was published signed by many of the principal physicians and merchants, in which they asserted an almost unanimous concurrence of the professional and other citizens
of Boston in assigning the merit of the discovery to Dr. Morton. In 1858 a similar appeal was made in New York, signed by the principal medical men of that city, and in 1860 also in Philadelphia. In 1858 he instituted a suit against a marine hospital surgeon for infringing his patent, as suggested by the president, which was decided in his favor in the United States circuit court. In the last year of his life he was engaged in agricultural pursuits, especially in the importation and raising of fine cattle at his farm in Wellesley, Mass. His death was caused by the excitement occasioned by an article attempting to deprive him of the honor of being the discoverer of anesthesia; this attack brought on a fatal congestion and syncope. A monument in Mt. Auburn was erected by citizens of Boston, with the following inscription, written by Dr. Jacob Bigelow: "Wm. T. G. Morton, inventor and revealer of anaesthetic inhalation; by whom pain in surgery was averted and annulled; by whom the medical art was raised, from whom science has control of pain." The Montyon prize medal, his orders received from Russia and Sweden, and the silver box presented in Boston, are deposited in the rooms of the Massachusetts historical society, Boston. (See Anæsthetics, Jackson, Charles Thomas, and Wells, Horace.)—See "Trials of a Public Benefactor," by Dr. Nathan P. Rice (New York, 1869).

Mosaic (late Gr. μοσαϊκος, belonging to the muses, polished, elegant, or well wrought), the representation of a design by fitting together on a ground of cement numerous small pieces of stone and glass, of various colors, and generally cubical. Although one of the most mechanical of the fine arts, it is entitled to rank as a style of painting, from the fact that it requires the preparation of a cartoon or colored design, as in the case of a fresco or an elaborate oil picture, and no considerable knowledge of form, color, and composition. Dating from a remote period, it has been transmitted to the present time, and in modern Italy has been carried to a higher degree of perfection than it attained at periods when it was almost the only species of pictorial art in vogue. Of the mechanical process employed, the following description of the practice in the establishment at the Vatican in Rome will convey an adequate idea: "The slab upon which the mosaic is made generally of Travertine or Tiberine stone. In this the workman cuts a certain space, which he encircles with bands or cramps of iron. Upon this hollowed surface mastic or cementing paste is gradually spread as the progress of the work requires it, thus forming the adhesive ground or bed on which the mosaic is laid. The mastic is composed of calcined marble and finely powdered Travertine, to which is added the consistency of paste with linseed oil. Into this paste are stuck the smalti or small cubes of colored glass which compose the picture, in the same manner as were the colored glass, stone, and marble sectilia and tesserae of the ancients. The smalti are vitrified but opaque, partaking of the nature of stone and glass, or enamels, and are composed of a variety of minerals and materials, colored for the most part with different metallic oxides. They are manufactured in Rome in the form of long, slender sticks, like the initials of different thicknesses, and are cut into pieces of the requisite sizes, from the smallest pin point to an inch. When the mastic has sufficiently indurated (and it acquires in time the hardness of stone), the work is susceptible of a polish like crystal. Care must be taken, however, that by too high a polish the entire effect of the work is not injured, as innumerable reflected lights in that case would glitter in every part of the picture. When the design is to be seen at a very considerable distance, as in cupolas or flat ceilings, the work is generally less elaborately polished, as the inequalities in the crossing distinguishable, and the interstices of the work cannot be detected by the spectator." By this process many copies of large pictures by Raphael, Domenichino, and other old masters in the Vatican have been executed, occupying periods of from 12 to 20 years, and requiring from 10,000 to 15,000 different shades of the primary colors for the purposes of the work. In 1858 Pope Pius IX. sent to the crystal palace exhibition of New York a mosaic copy of Guercino's "St. John the Baptist," valued at $60,000, which at a short distance it was impossible to distinguish from a highly finished oil painting. This, however, was a work of small importance in comparison with others preserved in the cathedrals of Europe. Two other species of mosaic work are carried on in Tuscany (whence the name, Florentine mosaics), the piétre due and piétre commesse, both of which are employed for ornamental purposes, and represent fruit, flowers, birds, &c. The former gives the objects depicted in relief in colored stones. The latter consists of precious stones, as agates, jaspers, lapis lazuli, &c., cut into thin veneer and carefully inlaid.—The employment of mosaics, which have always possessed a certain value, as well from their imperishable nature as from their intrinsic merits as works of art, originated probably among those eastern nations by whom so many of the arts have been transmitted to Europe. The Romans acquired a knowledge of the process from the Greeks, who borrowed it from the Asiatics; and by all of them it was originally applied as an ornament for pavements, the close imitation of inanimate objects scattered apparently over the floor being the chief aim of the artist. Large historical compositions, in which the mosaic represents the battle of Issus from the ceiling of the Vatican in Florence, are excellent examples, succeeded; and under the first Roman emperors the art attained a considerable degree of refinement, though still used chiefly as an
adorment for pavements. The Romans made it coextensive with their civilization, and from Britain to the Euphrates remains of ancient Roman mosaics have frequently been exhumed. Of the varieties in use among the ancients, the principal were the pavimento sectilia, consisting of floors formed of pieces of stone of different colors, cut geometrically and cemented together; the pavimento tessellata, or floors inlaid with small cubes of stone forming a colored design; the opus vermiculatum, and the opus musaeum, in which colored cubes of clay or glass of every conceivable tint, set up very much as types are by composers, were employed to produce elaborate finished pictures. The first three were included under the general name lithostrotum. With the overthrow of paganism and the establishment of the Christian religion commenced a new and grander era in the history of the art; and mosaics, from being used almost exclusively in pavements, were transferred to the walls and ceilings of sacred edifices. The connecting link between the mosaic pavements of Pompeii and the mosaics of Christian origin is so slight, that Dr. Kugler is "almost tempted to believe that historical mosaic painting of the grander style first started into life in the course of the 4th century, and suddenly took its wide spread." For nearly 1,000 years from this period it was almost exclusively employed for mural decoration, and from its durability has preserved a knowledge of the arts and in some degree of the religious ideas of the middle ages. From the 7th to the 9th century the most important and interesting remains of pictorial art are the mosaics in the churches and the manuscript illuminations; and the most ancient representations of the Virgin Mary now remaining are the old mosaics in the churches of Rome, Pisa, and Venice, referred to the latter half of the 5th century.

Christian mosaics admit of two general divisions, the later Roman and the Byzantine styles, the materials in use being in general cubes of colored glass, inlaid, in the Roman school, on a ground of blue or white, and in the Byzantine school on a gold ground, although in the latter the tesserae are frequently irregular in size and the workmanship coarse. The former style flourished in Italy chiefly in the 5th and 6th centuries, the most splendid specimens of it being found in the churches of Rome and Ravenna. The churches of Sts. Maria Maggiore in the former city and of San Vitale in the latter contain perhaps the finest. When in the 6th century the arts and sciences were driven out of Italy by the distracted state of the country, they found refuge in Constantinople, where about the commencement of the 6th century arose that peculiar style pervading many branches of the fine arts, to which the general name of Byzantine has been applied, and which for five succeeding centuries had a predominant influence throughout Europe and among many eastern nations. The first and greatest example of it is the celebrated church of St. Sophia, built by Justinian about the middle of the 6th century, and adorned with an almost incalculable wealth of mosaics, of which only a few colossal seraphim and the traces of a figure of the Madonna have escaped the effects of Mohammedan iconoclasm. By the middle of the 7th century it gained a foothold in Rome, where the native school of mosaics had lapsed into decay; and subsequently it came into competition with the Lombard, Norman-Byzantine, and Romanesque styles, each of which bore the influence of the parent Byzantine. The mosaics in the church of St. Mark in Venice, executed between the 11th and 14th centuries, are perhaps the purest specimens of the style in Italy. They cover a surface of about 40,000 square feet of the upper walls, wagon roofs, and cupolas, and are laid upon a gold ground. Others, in a different style, were executed as late as the 16th century, Titian, Tintoretto, and contemporary masters, in some instances furnishing the cartoons; and the whole is truly described as "a gigantic work which even all the wealth of Venice spent six centuries in patching together." In the 12th century a new or Romanesque style, founded upon Byzantine traditions, arose in Italy; and early in the 15th century the Italians in northern and central Italy, renouncing their dependence on Greek artists, began to execute mosaic work for themselves according to original conceptions of nature. Andrea Taffi, one of the earliest and most famous of the Italian mosaicisti, produced in the Saviour 14 ft. high, which, Vasari says, spread his fame throughout Italy. Contemporary with and immediately succeeding him were Jacopo da Turrita, the Gaddi, Giotto, and others, of whom the last executed the celebrated naricella, now in St. Peter's in Rome. Among the latest of the mosaicisti, who worked from their own or original designs, were Baldovineto, Ghirlandaio, the master of Michel Angelo, and Michiello, who brought the art to great perfection. At the commencement of the 17th century Clement VIII. employed numerous artists to decorate the interior of the dome of St. Peter's with mosaic copies of the works of eminent masters, and each succeeding century has added to the immense wealth in works of art of this description deposited in the church. In the 18th century Pietro Paolo Cristofori founded a school for mosaic in Rome, where the art is now practised on a grander scale than in any other part of the world.

MOSASAURUS, a gigantic fossil reptile, so named by Conybeare from its having been first found on the banks of the river Maas, near Maastricht in Holland, in the upper cretaceous formations of that district. It was referred to the orders of cetaceans and crocodilians, but A. Camper and Cuvier showed from the teeth and the skeleton that its true place was between the monitors and the iguanian lizards. The bones
of the head are like those of monitors; the teeth of the jaws are compressed, sharp-edged, supported on a socket in a shallow furrow, without true roots; there are teeth also on the pterygoid bones, as in the iguanians; there seem to have been 26 teeth in each jaw, with broad base and slightly curved. The head is elongated, and the mouth wide; the vertebrae concavo-convex, 34 from head to tail, the latter having nearly 100; as the articular processes are absent from the middle of the back, it has been inferred that

![Mosasaurus (restored).](image)

died March 10, 1870. At eight years of age he received musical instruction from F. D. Weber. In three years he became a skilful pianist; and at 14 he was introduced at Vienna to Haydn and Beethoven, and by their advice became the pupil of Albrechtsberger, with whom he made rapid progress. As a pianist he competed with Hummel, then reputed the first performer in Germany. After an extensive continental tour he in 1820 went to England, where he resided during the next 26 years. From 1825 to 1846 he was professor in the academy of London and conductor of the philharmonic concerts, after which he became musical professor in the conservatory of Leipzig. Probably no musician has so greatly influenced the cultivation in England of the classical music of Bach, Mozart, Beethoven, and kindred composers, or so fully developed a taste for pianoforte music and a knowledge of the resources of the instrument. As a performer of the sonatas and concertos of Beethoven he was without a superior. His compositions for the pianoforte are finished specimens of classical music, and his trios, quintets, &c., for the violin and other instruments, evince great theoretical knowledge. He translated into English Schindler's "Life of Beethoven," to which he added valuable notes.—See Aus Moscheles's Leben, edited by his wife (2 vols., Leipzig, 1872-73), and adapted from the German by A. D. Coleridge (London, 1879).

**Moschus**, an ancient people of Asia, S. of the Caucasus, whose territory at the time of Augustus was divided between Colchis, Iberia, and Armenia, and from whom a mountain range extending from the Caucasus to the Anti-Taurus received the name of Moschis mountains. Their name, in early classical writers, frequently appears coupled with that of the Tibarensi, and the two tribes are generally identified with the Mesheesh and Tubal of Scripture. (See Japheth.)

**Moschus**, a Greek bucolic poet, of the 3rd century B. C. He was a native of Syracuse, and a pupil of or for Dion. Four of his lost idyls and some small fragments of his poems are still extant, chiefly in the Doric dialect. They are usually joined with those of Dion and Theocritus. The best editions are those of Jacobs (Gotha, 1795), Wakefield (London, 1795), and Manso (Leipsic, 1807).

**Moscow** (Russ. Moskva). I. A central government of Russia, bordering on Tver, Vladimir, Riazan, Tula, Kaluga, and Smolensk; area, 12,554 sq. m.; pop. in 1867, 1,678,784. Its surface is low and undulating, and its soil is only moderately fertile. The climate is temperate in summer, but the cold is intense in winter. The navigable streams are the Volga and its tributaries, the Moskva and Kliasma. Cattle and horses are reared in great numbers, but the inhabitants are chiefly engaged in manufactures. It is divided for administrative purposes into 13 districts. II. A city, capital of the government, on the river Moskva, 390 S. E. of St. Pe-
MOSCOW

tarsburg; lat. of observatory, 55° 45' 19" N., lon. 37° 34' 4" E.; pop. in 1871, 611,970. It is surrounded by an earthen rampart more than 28 m. long. The enclosed space is an irregular trapezium, with an undulating surface, divided into unequal parts by the Moskva, which enters the circumvallation near the middle of the W. side and leaves it at the S. E. corner, finally joining the Oka, an affluent of the Volga. The little river Yauza, flowing from the northeast, joins the Moskva within the wall. About three fourths of the city lies on the N. bank of the Moskva, and one fourth on the S. bank. On the latter are the Sparrow hills, extending E. and W., which include nearly the whole S. part of the city. On the N. side the Kremlin (Russ. Kreml) occupies the principal elevation, directly on the bank of the river and very near the centre of the old city. From it radiate al-
magnificent and mean," is unequalled in picturesqueness. Its thousands of spires, domes, and minarets, diverse in form and color; its Kremlin with high walls and fantastic towers; its gardens, boulevards, and squares; the strange intermingling of pagodas, temples, and churches, of Chinese tea houses and French cafés, of Turkish bazaars and Russian market places, present a strange yet attractive panorama, combining the most striking European and Asiatic characteristics.—There are five principal quarters, the Kremlin, Kitai-Gorod, Bieloi Gorod, Zemlanoi Gorod, and the Slobodi or suburbs. The Kremlin, the ancient citadel, is a nearly triangular enclosure surrounded with walls from 28 to 50 ft. in height and about 11 m. in circuit, with massive towers at each angle, and battlements, embrasures, and numerous smaller towers be-
tween. It is entered by five gates, to each of which is attached a religious or a historical importance. The principal one, the Spasski or Redeemer gate, is reverenced by all Russians, and no person, not even the emperor, passes it without uncovering the head and making obe-
sance to the faded picture of the Saviour above it. The Nikolski or Nicholas gate has an image of that saint over it, and is only second in sacred associations to that of the Redeemer. By the Troitzy or Trinity gate the troops of Napoleon entered and left the Kremlin. Within the walls are cathedrals, churches, palaces, monasteries, and some of the finest public buildings and monuments of Moscow, with no symmetry of design, and of various styles and periods. The tower of Ivan Veliki (the Great), which looks down on all the surrounding spires, is an octagonal structure of five stories, its gild-
ed cross being nearly 325 ft. above the ground. 
In it are hung 34 bells, the largest of which weighs 64 tons. The Tzar Kolokol (see Bell) stands upon a granite pedestal near its foot.

The sacred buildings of the Kremlin are the cathedrals of the Assumption, in which all the Russian emperors since the days of Ivan the Terrible have been crowned; of the Archangel Michael, the burial place of the imperial family up to the time of Peter the Great; of the Annunciation, where the czars were formerly baptized and married; and the church of the Redeemer in the Wood, one of the oldest buildings in Moscow. Other ecclesiastical buildings within its walls are the Miracle monastery, the Ascension convent, and the sacristy or house of the holy synod, where are preserved the robes and the sacred vessels used by the different patriarchs. The palace is mostly modern, having been built chiefly by Czar Nicholas on the site of the old one burned in 1812. Within it are grand halls dedicated to the chief Russian orders of knighthood. The right wing, called the treasury, is devoted to the preservation of arms, armor, relics, regalia, and other treasures illustrative of the history of the reigning dynasty and of Russia. At the N. angle of the Kremlin is the arsenal, a massive building in front of which are ranged long rows of captured cannon, among them 365 pieces taken from the French in the retreat from Moscow. Opposite the arsenal is the senate house, where sits the high court of appeal. 

—The Kitai-Gorod (Chinese town), E. of the Kremlin, is surrounded by a wall with 12 towers and gates. It was enclosed by Helena, mother of Ivan the Terrible, when the Kremlin had become overcrowded. Within it the trade of Moscow has centred since 1566. The Gostinnoi Dvor, or great bazaar, is an immense building three stories high and covering three squares, intersected by numerous passages lined with shops. Each business has its separate department or street. The shops are small, but the store rooms above contain large quantities of goods, more than 75,000,000 rubles being invested beneath its roof. The Riad also, a large open square laid out in narrow streets of booths, is in this quarter. In the Krasnaya Ploshchad (Red place) is the cathedral of Vasili Blazhenni (St. Basil the Beatitude), sometimes called the cathedral of Kazan, because it was built by Ivan the Terrible over the remains of St. Basil, to commemorate the taking of Kazan. It is a building of two stories, with 11 domes and cupolas, each of different form, height, and color, and each surmounting a chapel dedicated to some saint. Other objects of interest in this quarter are the Romanoff house, where the founder of the present dynasty was born, the Strastni monastery, and the exchanges.—The Bieloi Gorod (white town) occupies the zone between the inner boulevard and the Kremlin and Kitai-Gorod. It contains many of the principal buildings, including the governor's palace, a fine building on elevated ground; the assembly house of the nobility, the grand hall of which will hold 2,000 persons; the university and the medical academy; the military riding school (560 ft. long by 158 broad), the roof of which is unsupported by any pillar, and which affords ample space for the simultaneous evolutions of 2,000 infantry and 1,000 cavalry; the foundling asylum, an immense quadrangular edifice, four stories in height above the basement, and having sometimes 25,000 children under its support, within and without its walls; the post office, the theatres, many private palaces, several monasteries and nunneries, and numerous churches. Among the last is the great temple of the Saviour, founded in 1812 to commemorate Russia's triumph over Napoleon, and not yet finished. It is a regular cross of four equal branches, surmounted by a central cupola 84 ft. in diameter, and having an exterior height above the pavement of 343 ft. The interior walls are faced with polished labradorite and porphyry, and adorned with paintings, and the outside is ornamented with bass reliefs repre-
senting Scriptural subjects and the events of the wars of 1812-'15. In the area in front are the statues of the Russian generals prominent in those times. — The Zemlianoi Gorod (earthen town), so called from the former earth rampart, now the outer boulevard, occupies the zone between the two boulevards. It contains the depot of the commissariat, the depot for spirits, the commercial school, the imperial philanthropic society, and many other public buildings, besides a large number of fine private residences. The Zatchatskiy mon astery, which takes its name from the church dedicated to the Zatchatiye or conception of St. Ann, is a great ornament to this part of the city. The church is a Gothic building, noted for the elegance of its interior. The Slobodi (suburbs) constitute all that part of the city outside of the Zemlianoi Gorod. Within its limits are most of the great monastic and benevolent institutions, a large number of churches, many parks and handsome residences surrounded by gardens, an imperial palace, the emperor's villa, the race course, the St. Petersburg railway station, &c. Among the great hospitals are the Galitse, Sheremeteff, St. Catharine, Alexander, St. Paul, and the military. The Novo-Dievitchie convent is a vast institution founded in the 16th century, with high walls surmounted by 16 towers. It has six churches, in the principal one of which are the tombs of many czarinas and princesses. Near it is the Dievitchie Pole or Maiden's field, where the people are entertained at the imperial coronations. The Seminof monastery, dating from the 14th century, is also surrounded by walls with high towers, one of which is 125 ft. high. It has six churches and a belfry 380 ft. high. The Novospasskiy monastery has five churches and a belfry 283 ft. high. The Daniloff monastery, with white walls, and the Donskoi, with red walls and battlements, have many churches, chapels, cloisters, gardens, and courts within their bounds. Without the St. Petersburg gate, a short distance beyond the circumvallation, are the Petrovski palace and gardens, a fashionable summer resort. Napoleon retired to this palace when the Kremlin became untenable. — Moscow has nearly 400 churches, all of the orthodox Greek faith, with the exception of the English and Roman chapels, a German and a French chapel, two or three Armenian chapels, and a Turkish mosque. It is the seat of one of the three metropolitans of the Russo-Greek church, and is excelled in ecclesiastical importance by St. Petersburgh only. It is the residence also of many of the great Russian nobles, particularly in the winter. Between it and St. Petersburgh exists a literary rivalry, which has done much to stimulate intellectual activity. Its schools and seminaries are celebrated. The university, a state institution under the authority of the minister of public instruction, has 100 professors and teachers and usually about 1,500 students. It has a library of 160,000 volumes, a cabinet of coins and medals, museums of natural history, a botanical garden, chemical laboratory, and observatory, a medico-chirurgical school and fine anatomical theatre, and a printing office. Among the other educational establishments are a Greek theological seminary, a practical commercial academy and a commercial school, an institute of oriental languages, five male and three female gymnasium, two military gymnasia and a military school, theatrical, mechanical, agricultural, veterinary, and other special schools, and numerous district and parish schools. The Catharine, Alexander, and Elizabeth institutes are for the education of young ladies of noble birth, and the Nicholas institute is for the instruction of female orphan children of the servants of the crown. There are several learned societies for the promotion of letters, art, and science; a public museum, with a library of 165,000 volumes and 5,000 manuscripts, a gallery of painting and sculpture, and a cabinet of coins and medals; and several other museums and libraries. Moscow is the centre of Panaslavism, and, though not now the political capital, is the real heart of Russia and the richest and most characteristically Russian of all the cities of the empire. It is the residence of the general commanding the military circumscription of Moscow, consisting of 12 governments, and of a military and a civil governor general; and is the seat of a division of the directoral senate, consisting of the 6th, 7th, and 6th departments for criminal and civil affairs. For administrative purposes it is divided into 21 districts. — On account of its central position and superior facilities for transportation, Moscow is the great entrepot for the internal commerce of the empire. It has water communication with the Baltic, the Caspian, and the Black seas, and is connected by railway with St. Petersburgh, Warsaw, Taganrog on the sea of Azov (by two lines, each with important connections), Nizhni Novgorod (with a branch to Kineshma), and Vologda. In the winter an enormous traffic is carried on by sledges with Tiflis and other places; and in 1874 a company was formed for trading with Afghanistan. It is also the centre of a great manufacturing industry, with several hundred establishments using steam power and the most approved machinery, and as many more in the surrounding towns and villages. Its chief manufactures are textile fabrics, principally of woollen, cotton, and silk, hats, gold and silver plate and jewelry, hardware, glass, porcelain, delft ware, paper, tapestry, chemical products, beer, brandy, and leather. Besides the Bindi and the Gostinoi Dvor, there are many other market places where a large trade is carried on. The horse market is of great importance. The so-called winter market presents a remarkable appearance during the winter, when the fish of the White sea and northern lakes, frozen oxen from the Crimea, Caspian sheep, and deer from the banks of the Irtil and Yenisei, are

Moseley thence to Ge- butburg. In the suburbs, nearly consumed by fire in 1536, in 1547, and again in 1571, when the Tartars set fire to the suburbs, and a large part of the population perished. During the insurrections caused by the pseudo-Demi-Brutus (1605–12), when the Poles and Cossacks took the city, it was again partly destroyed. In 1812 it was entered by the French under Murat on Sept. 14, and on the 15th by Napoleon, who took up his residence in the Kremlin. The city, deserted by its inhabitants, was set on fire by order of the governor, Count Rostopchin, compelling Napoleon to leave on Oct. 19, and to take his final departure on the 22d, and resulting in the disastrous retreat of the French army. The greater part of the city was then destroyed, notwithstanding the efforts of the French to stay the progress of the flames; but it was rebuilt within a few years.

Moseley, Henry, an English scientific writer, born about 1802, died Jan. 20, 1872. He took his degree at St. John's college, Cambridge, in 1826, took orders, and for several years he was professor of natural philosophy and astronomy in King's college, London. He was one of the first of the clergy to officiate as inspector of schools, and his services to education have been of great importance. He was for many years a member of the board of directors of the Bristol cathedral. He afterward became vicar of Olveston, and in 1855 chaplain to the queen. He published several scientific works, the best known of which are "Treatise on Mechanics applied to the Arts" (London, 1847), and "Mechanical Principles of Engineering and Architecture" (1855).}

Moseley (Ger. Mosel; anc. Moselle), an affluent of the Rhine, which rises in France, in the S. E. corner of the department of Vesoges, and flows N. and N. W. to Toul, in the department of Meurthe-et-Moselle (formerly Meurthe); thence its course is N. E. till it is joined by the Meurthe, when turning N. it passes through the former department of Moselle (now German Lorraine), and for over 20 m. forms the boundary between Rhinisch Prussia and Dutch Luxemburg. Then again turning N. E., it flows through Rhinisch Prussia to Coblenz, where it falls into the Rhine. The Moselle is about 320 m. long, more than 160 m. of which is through France. Its chief tributaries are: on the right, the Meurthe, Seille, and Saar; on the left, the Madon, Ornes, and Sure or Sauer. The principal cities on its banks are Toul, Metz, Troves, and Coblenz. It is navigable for more than 200 m., or from its junction with the Meurthe to its mouth.

Mosen, Julius, a German poet, born at Marienburg, Saxony, July 8, 1803, died Oct. 10, 1867. He was the son of a schoolmaster, and studied jurisprudence at Jena and Leipzig. After filling some inferior judicial stations in the provinces, he removed to Dresden, where he practiced his profession, and established a reputation as a poet and dramatic writer. In 1844 he was appointed dramatic writer to the court theatre in Oldenburg. Among his published poems are: Lied vom Ritter Wahn (1831); Gedichte, including Andreas Hofer (1836); and Ahnese (1838). His principal tragedies are: Die Bräute von Florenz und Wendelin und Helena (1836); Kaiser Otto III. (1840); Bernhard von Weimar (1855); and Der Sohn des Fürsten (1858). He wrote also the dramas and comedies Heinrich der Finkler (1836), Colo Rienzi (1836), Johann von Oesterreich and Die Wette (1842); and several fanciful novels, the principal of which is Bilder im Moos (1846). Two collections of dramatic works were published in Stuttgart in 1862, and his complete works in 8 vols. in Oldenburg (1863–4) and in Leipzig (1871).

Mosevithal, Salomon Hermann, a German dramatist, born of Jewish parentage in Cassel, Jan. 14, 1821. He took his doctor's degree at Marburg in 1842, became private tutor in Vienna, and in 1851 archivist in the Austrian ministry. His Deborah (Pesth, 1850) and Sonnenwendhof (Leipzig, 1856), have been adapted to the English, Italian, Danish, Hungarian, and Bohemian stage; and he has written many other dramas, among which is the tragedy (1846) of In the Saxon name of Kammermel Ge- dichte appeared in Vienna in 1866.

Moser, George Michael, an English enameller, born in Schaffhausen, Switzerland, about 1705, died in England, Jan. 23, 1788. According to Sir Joshua Reynolds, he excelled in his profession, had a universal knowledge in all branches of painting and sculpture, and "may truly be said in every sense to have been the father of the present race of artists." He was an original member of the royal academy, and for many years keeper of that institution, in which capacity he instructed the students in drawing and modelling from the antique. His daughter Mary (Lloyd), distinguished as a flower painter, was the only woman, with the exception of Angelica Kauffmann, ever a member of the royal academy. She died at an advanced age, May 2, 1819.

Moser. I. Johann Jakob, a German jurist, born in Stuttgart, Jan. 18, 1701, died there, Sept. 30, 1785. He was educated at the university of Tübingen, where at the age of 19 he was appointed teacher, and in 1727 professor of law. In 1736 he was made director of the
MÖSER

university of Frankfort-on-the-Oder, but resigned in 1739. In 1749 he founded at Hanau an academy for the instruction of young nobles in political science. In 1751 he returned to Würtemberg, where he was imprisoned from 1759 to 1764 for memorializing the duke on the rights of the estates. He was the first to give a systematic account of European international law. His works are very numerous, embracing the voluminous Deutsches Staatsrecht (Nuremberg, 1737–54), with various supplements. II. Friedrich Karl von, a German publicist, son of the preceding, born in Stuttgart, Dec. 18, 1728, died in Ludwigsburg, Nov. 10, 1798. He was for many years imperial councillor at the court of Vienna, and afterward a member of the administration of Hesse-Darmstadt. His Der Herr und der Diener (1759), exposing ad

MÖSER, Justus, a German author, born in Osnabrück, Dec. 14, 1720, died there, Jan. 8, 1794. He studied jurisprudence at Jena and Göttingen, and became government attorney in 1747; and for 20 years during the minority of the duke Frederick of York, who came into possession of Osnabrück in 1794, he was the principal adviser of the regent. He was afterward a judge. One of his most celebrated humorous works is his Harlekin, directed against pedants and hypocrites of all kinds. In his work on the German language and literature he attacks the ‘Gallomania and infidelity of Frederick the Great; and in a letter addressed to Jean Jacques Rousseau he opposes the theories of that philosopher. His most important contribution to literature is his Osnabrückische Geschichte (2 vols., 1768; 3d ed., 1829; vol. ii, published from his papers by his son, Karl von, 1824). His short essays, Patriotische Plastanien (4 vols., 1774–86), relate to local subjects. A complete edition of his works was published by Abeken (10 vols., Berlin, 1842–73).

MOSEIM, Johann Lorenz von, a German ecclesiastical historian, born in Lübeck, Oct. 9, 1694, died in Göttingen, Sept. 9, 1755. He was educated at the gymnasium of Lübeck and the university of Kiel, where he became pro

mentarii (1753). The best English translation of these works is by James Murdock, D. D., "Institutes of Ecclesiastical History" (3 vols., New Haven, 1832; revised, New York, 1899), and "Commentaries on the Affairs of the Christians before Constantine" (2 vols., New York, 1855).

MOSKWA, Battle of. See Borodino.

MOSELS. See Mohammedanism.

MOSQUE (Arab. meṣjid, "place of prayer"). A Mohammedan temple or house of worship. The first mosque was erected by Mohammed at Medina, part of the work being done by his own hands. The site was a graveyard shaded by date trees, which was selected by the prophet because his canad knelt opposite to it on his public entry into the city. The edifice was square and capacious, the walls of earth and brick, and the roof supported by the trunks of palm trees and thatched with palm leaves. It had three doors. A part of the building was assigned as a habitation to the poor among the faithful who had no other homes. In this mosque Mohammed was buried; and though the original edifice was long ago replaced by a larger structure, the temple still bears the name of meṣjid en-nabi, "the mosque of the prophet," and has ever since served as a model for the construction of Mohammedan places of worship. Everywhere the mosque is substantially the same in plan, though differing in detail in some countries, as modified by national taste. What in Arabia was simple and elegant in some highly ornate in Spain, florid in Turkey, and effeminate in India. In the reign of the caliph Walid I, toward the end of the 1st century of the Hegira, the cupola and the minaret were added to the mosque, and the Saracenic style of architecture was introduced throughout the Moslem world. The mosque of the prophet at Medina, the great mosque at Mecca, and the mosque of Omar at Jerusalem, are considered peculiarly holy, and are among the finest extant specimens of Moslem architecture. Other mosques, the chief of which, that of Sultan Hassan, is a majestic edifice in the purest style. The jumma meṣjid or great mosque at Delhi, built by Shah Jehan in 1631–7, is generally considered the noblest building ever erected for Mohammedan worship. The principal mosque of Constantinople was originally the Christian church of St. Sophia. The mosque of Soylyman the Magnificent, begun in 1550 and finished in 1555, has six minarets. Attached to this mosque, as to almost all others, are various endowments for institutions of education, piety, and benevolence. It has an annual revenue of 300,000 piasters.

MOSES (músc), a large family of cryptogamic plants, the study of which forms a distinct department of botany called bryology (Gr. σπόλον, moss), or muscology. Moses have distinct stems, leaves, flower-like reproductive
organs, and seed-like bodies or spores which serve to propagate the species. They are cellular, and bear only a faint resemblance to the higher orders of plants. The stem of the mosses consists of cells of different forms and sizes, as may be readily seen by a transverse section, where those of the circumference are smaller and polyhedral, while those of the centre are elongated and by a closer arrangement approximate a woody texture. The stem, when it rises upward and ends in the organs of reproduction, is said to be determinate, and such a moss is acrocarpus; but when it extends lengthwise and laterally in an indefinite manner, it is said to be indeterminate, and the moss is pleurocarpus, because the reproductive organs are borne upon the side branches. The leaves of mosses are always sessile, and usually clothe the stem; but in some species the lower part is bare, or at least only covered with a few leaf-like scales. There are two distinct kinds of leaves: 1, those which grow upon the stem, and are called cauline; 2, those which surround the reproductive organs, and are called perichetal when they surround the fertile organs, and perigonal when around the male. These latter are more closely set than are the others, forming a sort of rosette in the centre of which the reproductive organs are lodged. The leaves of mosses are very simple, and usually consist of a single cellular layer, and they are destitute of stomata. They easily imbibe moisture, and as suddenly wither. A passing shower will revive the mosses which grow upon the driest rocks. The cells of the leaves are comparatively large, but the size differs greatly in different species. Each cell usually contains chlorophyll, though the cells of the sphagnum appear to be destitute of this principle. The cells are often uniform in size and general shape, except those toward the central portion of the leaf, where they assume an elongated form and constitute themselves into a sort of rib, nerve, or vein, which either bifurcates at the base and shortly ceases, or is produced into a single nerve and continues through the greater length of the leaf, or even extends beyond the apex and ends in a sort of point. The cells upon the edges of the leaf are sometimes modified into a border or into serrated processes like teeth. Sometimes several laminae are produced along the midrib or nerve of the leaf, and sometimes granules or bulbules are produced there. Buds or innovations are also sometimes to be met with in the axils, which when separated can become new plants. With regard to the stem, the phylotaxis or position of the leaves is one-two, two-five, or three-eight. The floral or reproductive organs are of two kinds: 1. What may be regarded as the sterile or male flowers, the antheridia, consisting of cylindrical, pear-shaped, or ellipsoidal stalked sacs containing a granular mucilage, which when the antheridium is mature is expelled from an opening in the apex; it consists of spherical hyaline cells from \( \frac{1}{80} \) to \( \frac{1}{70} \) of an inch in diameter, each containing a filiform antherozoid, which is furnished with two minutely slender, vibrating hairs. The antheridia are accompanied by cellular jointed filaments called paraphyses. 2. The archegonia, which may be compared to fertile or pistillate flowers, are usually flask-shaped bodies, mixed, like the antheridia, with paraphyses, and like them produced within small clusters or rosettes of leaves. The cavity of the archegonium contains a free cell or nucleus, enveloped by mucilage; after fertili-
cap, called the calyptra; the nucleus in elongating forms a slender bristle, still capped by the calyptra, and when it has attained its full length the portion within the calyptra expands, and forms a capsule (theca, or urn), which is known as the fruit of the moss. The lower portion of the ruptured archegonium remains at the base of the bristle as a vaginula or sheath. In general, a single archegonium only becomes perfect and undergoes these changes. These two distinct kinds of floral organs sometimes exist in the same flower and are enclosed in the same perichaetium, when the moss is called synnicious; if, however, the antheridia occur on one part of the plant and the archegonia on another part, the moss is called monocious; and when each kind of organ occurs on separate plants, the moss is dicous. The importance of these differences in the mosses is apparent from the fact that some species produce in some countries only barren flowers or antheridia, and consequently can never be found there in fruit, a condition always desirable to those who collect for herbaria. It has been well ascertained that where the antheridia are wanting the archegonia never come to perfection; and there are some dicous species of hypnum, for instance, which are usually destitute of capsules from that cause. The capsule, sporangium, or theca of mosses is cellular, has a central axis called the columella, and contains spores. In some instances the sporangium is indehiscent (e.g., phaseum); in other cases it opens by four lateral valves (andrea), but in the majority of mosses it opens by means of a lid (operculum). This lid is thrown off when the sporangium is mature. Between the base of the lid and the edge of the mouth of the capsule or sporangium are frequently several rows of large cells forming a sort of ring (annulus), which distend themselves and assist in the dispersion of the spores. The edge of the mouth of the capsule in some mosses is entire (e.g., gymnostomum), or it has a fringe (peristome) consisting of prolongations and divisions of the two inner parietal layers of the capsule. The peristome consists of one or more rows of hygroscopic cellular teeth, which are four or some multiple of that number. Where but a single row exists, the mosses are classed as aploperistomi, and where there are double rows as diploperistomi. The teeth are long and twisted together in barbula, or bifurcate in dieranum, or assume a variety of shapes, marking the different genera. In some mosses the inner parietal layer appears as a membrane called the epiphragm or tynpanum, stretched across the mouth from the walls of the sporangium to the columella. The capsule does not always rest in a perpendicular manner upon the seta, but may be inclined to one side, and bent downward or cernuous; and in some mosses one side of it is more developed than the other, producing an asymmetrical shape. Sometimes there is a considerable thickening or swelling at its base, to which the name of apophysis is given. The interior of the mature capsule is filled with a profusion of dust, which however will be found to consist of round bodies, which are in fact the spores or seeds. When they have been ejected from the capsule, they are in a condition to grow. From some part of their surface a bladder-like swelling protrudes, which after a while extends itself by increase of similar ones into a conflervoid thread. An entangled mass of such threads soon covers the soil, or the moist surfaces of substances on which the spores have fallen. So much do these threads resemble some of the algae, that they were mistaken for them by the earlier botanists. This conflervoid vegetation continues from 5 to 20 days, when upon its surface very small buds appear. On examination these buds will be found to be composed of minute scaly leaves; and thus the axis or future stem is originated at their base. In some genera the moss scarcely develops itself beyond this condition, forming its fruit in the interior of the scale-like foliage. In other kinds of mosses the plants grow for a shorter or longer period of time before the inflorescence appears. These conflervoid threads have been compared to the primordial leaves of the higher orders of plants; they differ however in this, that on disappearing from the surface of the soil, similar threads penetrate it and seem to careless observers to be the roots. In many mosses such seeming roots are pushed from the under side of the stem, or even from the very extremities, in the progress of its growth.—Very little is known of the uses of the mosses. In the economy of nature they serve as precursors of the higher plants, appearing first upon sterile places, and collecting among their matted and tufted stems the dust and sand. They afford secure lodging places for insects in winter, as well as food for them in summer. Some species of sphagnum enter largely into the formation of peat bogs; in these localities the moss continues to grow above while it is constantly decaying below; a great number of woody plants are found growing with the sphagnum, and these decaying together with the moss form peat of various qualities. Some botanists regard sphagnum as sufficiently different from other mosses to form an order by itself (sphagna), intermediate between the true mosses and the liverworts. When first taken from the bog sphagnum is very wet, but if thor-
oughly squeezed or partly dried it serves an excellent purpose in the transmission of trees and plants by packing their roots in the spongy and elastic mass; indeed for this purpose it is superior to all other packing materials; it may be made to contain just the requisite amount of moisture, and it does not readily decay. It is also much employed by gardeners as a medium in which to grow orchids and plants. Mosses are naturally inhabitants of bogs, and for these uses it is a regular article of trade. Some hypna retain their elasticity on being dried, and serve for stuffing pillows. The Laplanders use turfs of polytricha for mattresses. Little brooms are sometimes made of these mosses. In dense forests (in the northern hemisphere) the northern side of trees is usually more thickly covered with mosses than the other sides. Some fanciful medicinal qualities are attributed to a few kinds.—The geographical distribution of the mosses is very extensive, but only a part of their surface is destitute of them, from the polar regions to the equator. They constitute with lichens almost the only vegetation on the coast of the Polar sea, where the soil never thaws to a depth of more than a few inches. The northern seacoast of Siberia is an immense morass whose entire surface is covered with mosses. The schistose rocks of Spitzbergen, rising above the everlasting ice, are, according to Martens, covered with these plants. They enter largely into the flora of Greenland; the loftiest Swiss Alps, and the volcanic scoriae of Iceland, afford abundant species. Montague in his Synology exhibits species from almost every portion of the globe, and the various exploring expeditions find these forms of vegetation wherever they have visited.—The earliest writer on the mosses who comprehended their structure was Micheli, who in 1729 described and depicted the most minute portions of their reproductive organs, and seems to have understood their purposes. On the other hand, Dillenius (1741), Linneus (1753), and Adanson (1768) regarded the sporangium as analogous to the anther of the phanogamous plants. Schmiedel in 1760, and subsequently in his Icones Plantarum et Analysae Partium (1762-'97), described and figured the fruitlet of the hepaticæ; and, struck with finding them filled with a mucilaginous fluid analogous to that which fills the pollen grains, he considered them as male organs, and gave the name of female organs to the sporangia of mosses. Hedwig (Theoria Generationis, 1784) and other botanists now adopted the same view, until H. Mohl in 1833 showed that the spores of the hepaticæ and mosses were developed exactly like the pollen grains, and that the ideas of Linneus and others of that school were in a measure correct. We have seen, however, that the antheridia with their enclosed antherozoids seem to be essential in the production of the sporangium and its contents. In the United States the mosses were perhaps first collected by Dr. Muhlenberg, of Lancaster, Pa. He sent many American species to Hedwig, and they were described and published in the Species Muscorum (Leipsic, 1801). In 1813 Muhlenberg's Catalogus Plantarum America Septentrionalis appeared, in which he gives the names of more than 170 species. The value of this list is apparent, when it is known that his correspondence abroad was extensive and highly prized. Many of the species in Bridel's Bryologia Universæ (Leipsic, 1826) were from contributions of Dr. Torrey of New York, who at that time had made ample collections of cryptogamic plants; and mention is frequently made by the same author of the names of Cooley and Dewey, who likewise furnished specimens. Those of Newfoundland had been collected by De la Pylaie. A synoptical table of the ferns and mosses of the United States was published in 1828 in the "American Journal of Science and Arts," vol. xv., by Dr. Lewis C. Beck. A list of British mosses was published (1828) in full of the second edition of Prof. Hitchcock's "Geological Report" of that state. The mosses of the British possessions in North America were collected by Drummond, the author of Musci Scotici, who accompanied Franklin in his second land expedition in 1825. These subsequently appeared in sets of mounted specimens published by William Wilson at Glasgow in 1828; they were choice and valuable. In the Boston "Journal of Natural History" for 1845 (vol. v.) is a paper by John L. Russell on some species noticed by him in eastern Massachusetts; and in Hovey's "Magazine of Horticulture and Botany" for 1847, vol. xiii., is a valuable list of White mountain species prepared by William Oakes, who had made that region of New England his special study. In the catalogue of the plants of Cincinnati, Ohio, by Thomas G. Lea, are more than 80 species collected by him. In Agassiz's "Take Superior, its Physical Character, Vegetation," &c. (Boston, 1850), the mosses of that region are elaborated by Lesquereux. Dr. Darlington, in the second edition of his Flora Cestrícia (Philadelphia, 1853), furnishes a list of species detected within the limits of Chester co., Pa., and prepared by Thomas P. James. The Musci Alleghanienses were issued from Columbus, O., in 1855, in two fascicles (4to), consisting of 215 species and well marked varieties of mosses, and 177 species of hepaticæ. Fifty copies only of this superb work were printed for private distribution among the friends of the author. These specimens were collected by William S. Sullivant and Prof. Asa Gray, in a tour along the Alleghany mountains from Maryland to Georgia in 1853. A similar work from the joint studies of Lesquereux and Sullivant, consisting of 325 mounted species, and entitled Musci Boréal-Americani (Columbus, O., 1856), full of beautiful text and wood engravings, gives a survey of the flora of the northern states, giving a view of the muscology of North America, furnishes ample materials for comparison. In the second edition of Prof. Asa Gray's "Man-
ual of the Botany of the Northern United States" (1856) Mr. Sullivant gave descriptions of all the species known eastward of the Mississippi river; but in subsequent editions of the "Manual" these are omitted, and they have been published in a separate volume as "The Musei and Hepaticae of the United States east of the Mississippi River." A most important aid to the student is "The Icons Micrcorum, or Figures and Descriptions of most of those Mosses peculiar to Eastern North America which have not heretofore been figured." This, also by Mr. Sullivant, is a handsome volume, with 129 copperplates, each illustrating several species. A description of the mosses and liverworts found on the United States Pacific railroad expeditions and surveys, with figures of the rarer and new species by Mr. Sullivant, can be found in the fourth volume of the executive documents (Senate) of the 30th congress, second session (Washington, 1856). Other valuable contributions to the branch of botany from the same pen are to be seen in the "Memoirs of the American Academy of Arts and Sciences" (Boston, 1848, &c.).

The species found in Wisconsin are given by I. A. Lapham, in the fifth volume of the "Transactions of the Wisconsin State Agricultural Society" (1860). Many novelties likewise have been brought to notice through the labors of C. C. Frost of Brattleboro, Vt., and by Prof. D. C. Eaton of New Haven, who have minutely examined that region. Mr. C. F. Austin, of Closter, N. J., has published named collections of mosses. The "Bulletin of the Torrey Botanical Club" (monthly, New York) contains important contributions to our mycology by Mr. Austin, and, especially with reference to southern and far western species, by Dr. Carl Müller of Halle, Germany.

MOSTAR, a town of European Turkey, in the vilayet of Bosnia, capital of Herzegovina, on both sides of the river Narenta, 38 m. S. W. of Bosna-Serai, in lat. 43° 20' N., long. 17° 58' E.; pop. about 18,000. The buildings are scattered over a plain through which the river runs, and the only noteworthy ones are the governor's palace and a few of the mosques, of which there are more than 30. There is also a Greek church, and the town is the residence of the Greek metropolitan of the district. There are two bazaars, and an extensive trade is carried on in agricultural products and silk. Mostar was founded about 1440, and named after the bridge crossing the Narenta at this point (Most Star, old bridge), which was probably built in the time of Trajan or Hadrian, and still connects the two portions of the town. It consists of a single Roman arch, 95 ft. in span and about 80 ft. above the stream in summer.

MOSUL, or Mousul, a town of Asiatic Turkey, capital of a district of the same name in the vilayet of Diarbekir, on the right bank of the Tigris, 220 m. N. W. of Bagdad; pop. about 40,000, of whom 9,000 are Christians, 1,500 Jews, and the rest Arabs, Turks, and Kurds. Its fortifications are dilapidated. The streets are narrow and irregular; the houses, mostly built of a composition of pebbles, lime, and clay, have flat roofs surrounded by parapets, and the stairs are always on the outside. It is one of the chief centres of the Jacobites, their bishop, next in rank to the patriarch, residing in a neighboring convent; there are also United Syrian and Chaldean bishops, and the Chaldean patriarch of Babylon usually resides here. It once had considerable commerce, and it is still a mecca for the trade between Bagdad, Syria, and Constantinople. Its manufactures are chiefly coarse cottons and shawls. In the middle ages it was noted for its muslin, with which it supplied Europe, and which derived its name from this place.

The climate is very hot in summer, but the winters are mild and agreeable. In the vicinity are several hot sulphur springs which are much frequented. Mosul is chiefly interesting as being near the covering of Nineveh, remains exist in great mounds on the opposite side of the river, excavated by Botta and Layard.

MOTH (phalera, Linn.), the common name of the third and last section of the order lepidoptera, the other two having been described under BUTTERFLY and HAWK Moth. This section includes a great number of nocturnal insects, also called night butterflies and millers, including all that cannot be arranged under the other sections. They vary greatly in size, color, and form; while those with gilded wings are very minute, the atlas moth of China (attacus atlas) covers a space 9 by 1/4 in. with its expanded wings, and the owl moth of Brazil (crebus strize) expands 11 in. The antennae are usually tapering, either naked or feathered, varying according to sex, and amplexus in the males; the wings are bridled by bristles and hooks, the first pair covering the thorax of the females, and the hind legs have two pairs of spurs. The tongue in most consists of a sucking tube formed of two hollow threads, rolled up when not in use; in some it is very short or wanting; there are generally two feelers, curving upward from the lower lip. The legs in the larvae vary from 10 to 16; some in this condition are smooth and naked; others hairy uniformly or in tufts, others warty or spiny; some enclose themselves in silken cocoons (as the silkworm), others enter the ground, or undergo their change in the interior of plants; the chrysalids are oval without angular elevations. Most moths conceal themselves by day, flying only at night and during the warm season; a few, as some bombyces, fly by day and in the brightest sunlight. Modern entomologists generally recognize seven groups, as follows: I. Bombyces or spinners, including Latreille's four sections of hepialites, bombycloptera, pseudo-bombycloptera, and aposeura. This, the
largest group, was so named from bombyx, the old name of the silkworm, and its members are generally thick-bodied, with feathered antennae (at least in the males), very short or no feelers, with woolly thorax, and the fore legs often hairy; the caterpillars have 16 legs, and in most cases spin cocoons in which metamorphosis takes place. After Boisduval, Dr. Harris divides this group into nine families: 1. Lithosiadae, so called from their caterpillars living in stony places and often feeding on the lichens growing upon rocks. Many of the species are very handsome, but injurious from devouring grass; they are small, slender-bodied, with long bristly antennae, narrow fore wings, and smooth back; they often fly in the daytime; their caterpillars are sparingly clothed with hairs growing in clusters from small warts, and enclose themselves in cocoons of silk interwoven with their own hairs; the rings of the chrysalids are closely joined. The most elegant species is the Deiopeia bella, with white body, thorax dotted with black, fore wings deep yellow crossed by about six black-dotted white bands, the hind wings scarlet bordered with black behind, and a spread of about 1 ½ in.; it can hardly be called injurious to vegetation. 2. Arctiadae, tiger and ermine moths, called woolly bears from the thick hairy covering of most of their caterpillars. The tongue is generally very short, and the antennae doubly feathered on the under side, hardly visible in the females; feelers shorter and thicker than in the preceding family; wings rooded on each side, thorax thick, abdomen short and plump, generally with black spots; they fly only at night. The hairy caterpillars run very fast, and when irritated roll themselves into a ball; some, like the salt-marsh caterpillar and the yellow bear, are very injurious to vegetation; when about to change they creep into a protected place, and make a cocoon of their own hairs and a little silk; the chrysalis is smooth, with movable joints. Most of our tiger and ermine moths belong to the genus arctia (Schr.). The largest is the A. virgo, which gives out a very disagreeable odor; it expands 2½ in., and the wings are reddish; the larva is brown. The great American tiger moth (A. Americana), represented in Europe by the A. caia, expands 2½ in.; the fore wings are brown marked with white, and the hind ocher yellow spotted with blue black, and with a white edge on the collar; the caterpillar is blackish brown. The yellow bear (A. [S.] Virginianus) is very common and destructive in gardens, devouring almost all kinds of plants; the moth is called the white miller, and would be called an ermine moth in England. The salt-marsh caterpillar (A. [S.] acroa) is a great pest to the salt-hay crop; it appears toward the end of June, attaining the full size during August, nearly 2 in. in length. The Isabella tiger moth (A. Isabelle) is remarkable for the silk it spins in the form of its body covering, black toward the head and tail and tan- red between, with black body and head; the moth is tawny yellow with black dots, and the antennae are not feathered. Some arctiads devour the leaves of trees, the most familiar and destructive of which are the fall web worms (A. [S.] textor); the brood make a web in common, sometimes extending over entire branches, and feed in company under its protection, devouring the upper and pulpy portion of the leaves; when full grown they are a little more than an inch long, and are thinly clothed with hairs; the general color is greenish yellow dotted with black, the head and feet black; the moths are white, with tawny yellow fore thighs and blackish feet; the wings expand about 1 ½ in. For full descriptions of these and other arctiads, see Dr. Harris's work on "Insects Injurious to Vegetation." 3. Lepidoptera, so called from the thickness of the body of the females, which are sometimes destitute of wings, while the slender males have broad wings; the antennae are bowed and doubly feathered below; the feelers are very hairy, as are the fore legs; the males sometimes fly by day. The caterpillars are in most half naked, the thin hairs growing chiefly on the sides; they are called tussocks in England, and have sometimes proved very destructive there; they are far less common and injurious in this country, where they are called vaporer moths; they belong to the genus orgyia, among others. 4. Lasiocampidae, with very thick woolly bodies, without the usual bristles or hooks to the wings, with the front edge of the hind wings turned up; the larvae are generally not witty, and are sparingly clothed with short soft hairs, mostly on the sides; both sexes are winged, and fly only at night. Here belong the tent or lackey caterpillar, common in neglected orchards; the eggs are placed as little cylinders around the ends of branches, and the larvae when hatched make a tent like a spider's web between the forks of the branches of apple and cherry.
trees; they spin from the mouth a silken thread which serves to conduct them to the tent in their search for food, and in this manner their pathways become in time well car-

peted and secure. They are called lacceyes in England, and tieréés in France, from their parti-colored livery of white, black, and yellow. The American tent caterpillar or lackey (elisocampa Americana) is so abundant and so well known as one of the worst enemies in the orchard, as to receive in many districts the name of "the caterpillar." The lappet moths are so called from the hairs which grow from fleshy or warty appendages that hang like legs from the sides of every ring; the American lappet moth is the gastropacha Americana, described in Dr. Harris's work above cited. The Chinese silkworm (bombyx mori), which belongs here, is noticed under Silkworm, and the processioon moth (B. processionana) under Caterpillar. 5. Saturniidae, containing some of the largest and handsomest moths, with thick woolly bodies, widely feathered antennae, and wings without bristles or hooks, and generally with a conspicuous spot in the middle of each; they fly during twilight. The most beautiful of all is the luna moth (attacus luna), with long-tailed wings of light green expanding 4½ to 5½ in., each having a transparent spot encircled with white, red, yellow, and black; the larva is bluish green, from 2 to 3 in. long, and when at rest nearly as thick as the thumb; it is found on walnut and hick-orvy trees, and spins a strong cocoon within a cavity formed by the drawing together of a few leaves. The polyphemus moth expands 6 in., and is of a dull ochre yellow color, without tails to the wings. The A. Ceropria expands to 6½ in., with rounded untailed wings of a grizzled dusky brown, with a red eye spot with white centre and black edge. The A. Promethea expands to about 4 in. All these moths make very large cocoons entirely of silk, surpassing in strength those of the silkworm, and capable of being manufactured into very durable fabrics. Two other moths of this family, whose processionary larva are furnished with severely stinging prickles, are the Saturnia Jo, expanding from 2½ to 3½ in., and the S. Maia, resting like the former with the wings closed, expanding to about 3 in. 6. Cerato-campod, or horned caterpillars, being armed with thorny points, some of the anterior long and curved like horns; in the moths the short antennae are feathered at the basal half and thence naked to the tip; the wings, closed when at rest, have no hooks nor bristles; this family, according to Harris, is exclusively American. One of the largest, rarest, and most magnificent is the royal walnut moth (ceratocampa regalis), expanding 5 or 6 in., the fore wings olive-colored with yellow spots and red lines, the hind wings orange red with yellow patches and olive spots; the horns of the formidable-looking larva are unable to wound. Other horned larvae belong to the genus dryocampa, as the imperial moth (D. imperialis), with yellow wings sprinkled and spotted with purple brown, expanding to about 1 ft. long. Eucerada or hepiadea, whose larvae are concealed in the wood and pith of plants like the borers of the hawk moths; these larvae are whitish, soft, nearly naked, with horny heads, and 16 legs; they make imperfect cocoons. Here belong the ghost moth of Europe (hepialus humuli), very injurious to the hop vine; the famous costus ligniperda, so destructive to the elm and willow; and various borers of the locust tree in this country, the carpenter moths of the genus xyleutes (Newman), which includes the C. ligniperda; the last are sometimes called goat moths from their strong odor. 8. Psychidae, or sack-bearers, from the larva bearing about with them cases in which they live, made of bits of straw, leaves, and sticks, and lined with silk; they undergo their change within these; here belong the genera psyche, actiaceus (drop or basket worms), and perophora. 9. Notodonta, so called from the bunched or toothed back of the larva; some are naked, others slightly hairy, with 16 legs, of which the last pair are sometimes modified into a forked caudal appendage; some seem to be without legs, showing only the soles of the feet. Here belong the odd-shaped limacodes or slug caterpillars, found on forest and orchard trees; the diecavura or fork-tails, the last pair of legs being held upward; and the various species of the old genus notodonta, as the N. unicornis and concina. ii. Nocvus or owlet moths, equivalent to the noctualitites of Lattreille, so called from their flying chiefly at night like owls. This tribe contains many thick-bodied and swift-flying moths, which generally have long and tapering antennae, long tongue, distinct feelers, wings fastened by bristles and hooks and rooted when at rest; the colors are usually dull, and shades of gray or brown; the larva are for the most part naked, slow-moving, usually with 16 legs, and nearly cylindrical; some make cocoons, while oth-

dle worms; the agrotidians or rustic and dart moths and cut worms; and the manestrians, like the zebra, painted, and wheat caterpillars, and cotton worms. III. Geometra or phaenites of Latreille, including the geometrids, spanworms, and looper, so called from their manner of moving. The characters of this tribe are sufficiently given under CANKER WORM. It contains the genus phalaena, which has been divided into many subgenera. IV. Pyralides or delta moths (included in the dettiloides and tineides of Latreille), nearly allied to the geometrids, and so called from the triangular form of the closed wing; the body is long and slender, the fore wings rather narrow and elongated, antennae long and generally simple, and the legs slender; most of them fly by night, preferring moist localities. Here belong the meal moth (pyralis farinalis), the grease or tabby moth, the day-flying simaethis (remarkable for their gyrations after alighting), the aquatic hydrocanopa, &c. (living in cylindrical leafy cases in the larva state), and the hop-vine hypena. V. Tortrices or leaf-rollers, so named from the habit of most of their larvae of making rolls of leaves fastened by silk, serving both for habitations and food; they have 16 legs, and are mostly naked. The moths rarely exceed more than an inch, and carry their wings when at rest like a steep roof; the fore wings are very broad at the shoulders, and are generally prettily banded and spotted; the hind wings are plain; the antenna-thread-like, the tongue short, the body thick, and the legs short; they fly only at night, and are most abundant in midsummer. The bud caterpillars are frequently very injurious in orchards and flower gardens, fastening the tender leaves together and eating the substance of the bud, and some bore into and destroy young fruits; apricots, peaches, and plums often suffer much in this way. The turpentine moths pierce the tender shoots and terminal buds of the fir and pine trees, the seat of their depredations being indicated by the oozing of the resin. The moth of the apple worm (carposcopa pomonella), which expands three fourths of an inch, may be known by a large oval brown spot, edged with copper, on the hinder margin of the fore wings; they lay their eggs on the young summer apples in July evenings, dropping them one by one in the hollow at the blossom end of the fruit; the larvae are hatched in a few days, and at once burrow toward the centre; only one being commonly found in each fruit; it reaches the full size in about three weeks, by which time it has burrowed in various directions, getting rid of the refuse fragments by a hole which it gnaws in the side, through which it also escapes after the premature fall of the fruit; they make silken cocoons, and are not generally changed to moths till the following summer. Pears and cranberries are affected by a worm apparently the same as that of the apple. VI. Tineas (tineites, Ltr.), the moths par excellence of the household, the destroyers of clothing, carpets, furs, &c., and those referred to in the Scriptures and by the old writers. The larvae are smooth, with 16 feet, living usually in cases made from the fragments of the substances which they devour fastened together with silk, in which they move freely and unseen. Though the smallest of the lepidoptera, they are among the most beautiful and the most destructive. Here belong, among the crambida, the bee or wax moth (galleria cereana), carpet moth (T. tapetella), fur moth (T. pellionella), hair moth (T. crinella), and grain moth (T. granella); and among the pomonitae, the pack moth (anaeopila sacritella), destructive to wool and its fabrics, and the Angoumois grain moth (butalis cereatella). The best preventives against moths in household articles are to put them away before May or June when the moths cannot reach them when about to lay their eggs; to expose them to the air and sun for hours, after a good beating to dislodge any insects or eggs; to brush over their retreats with turpentine; to stuff camphor, black pepper, tobacco, or shavings of Russia leather under or among carpets, woolens, furs, or coverings; when they are put away for the summer; the use of camphor wood or cedar trunks; corrosive sublimate washings, tobacco, and sulphur fumigations, and the action of heat and steam. For an account of the American and European grain moths, see WHEAT MOTH. VII. Alucite or feather-winged moths, equivalent to the pterophorites of Latreille. These may be known by the longitudinal division of their wings into narrow fringed branches like feathers; the antennae are slender and tapering, the tongue long, the body and legs long and slender, the wings at rest held outstretched, as if spread like a fan; the flight is slow and feeble, sometimes diurnal, sometimes nocturnal; the larvae are short and thick, slightly hairy, with 16 legs, living on leaves and flowers, and constructing no cases. There are few species, and they are rarely injurious to man. MOTHE (or Motte) CADILLAC. See CADILLAC. MOTHER CAREY'S CHICKEN. See Petrel. MOTHER OF PEARL. See Pearl. MOTHERWELL, William, a Scottish poet, born in Glasgow, Oct. 13, 1797, died there, Nov. 1, 1835. He was educated at the grammar school in Paisley, and at the age of 15 was placed in the office of the sheriff clerk of that place. He was sheriff clerk depute of the county of Renfrew from 1819 to 1829. In 1819 he edited the "Harp of Renfrewshire," a collection of songs and poems. In 1827 appeared his "Minstrelsy, Ancient and Modern," with an elaborate historical introduction and notes, and several original poems in antique guise. He edited for a year the "Paisley Magazine," and printed in it some of his best poems, and between 1828 and 1830 conducted the "Paisley Advertiser." In the latter year he took charge
of the "Glasgow Courier," a journal of very decided Tory principles, with which he remained connected until his death. In 1832 he published "Narrative and Lyrical Poems," and soon after commenced in conjunction with James Hogg an annotated edition of Burns' works, which he did not live to complete. In 1849 a greatly enlarged edition of his poetical remains, accompanied by a memoir, was published in London. The heroine of his most famous poem, "Jeanie Morrison," a schoolmate, did not know that it alluded to herself until her publication, when she was married to a Mr. Murdoch. Motherwell continued to alter the poem as long as he lived.

**MOTHERWORT** (Leonurus cardiaca; Gr. λιβεω, a lion, and καρδια, a heart), a plant belonging to the mint family or labiate. It is met with around walls, fences, and neglected spots near farms and gardens. The root is perennial, stem 2 to 5 ft. high, branching near the base, and downy;

leaves 2 to 4 in. long, lobed and broad, growing narrower toward the top of the stem, the uppermost wedge-shaped at base and three-lobed at the apex, all bending downward.

The flowers are borne in many whorls; the calyx has rigid and prickly teeth; the corolla, hairy without, is pale purple; the nutlets containing the seeds are triquetrod and truncate at summit. Another species, *L. marrubiastrum*, has become partially naturalized in some districts of Pennsylvania; it is a tall biennial with oblong-ovate stem leaves and whiter flowers. The common motherwort has a strong, pungent odor, and a bitter taste, and, as its name indicates, has been used as a remedy in diseases of females, and at one time it acquired a reputation in Russia as a preventive of hydrophobia; at most it is an aromatic tonic, and its use is now confined to domestic practice.

**MOTION.** See Mechanics.

**MOTLEY, John Lothrop,** an American historian, born in Dorchester, Mass., April 15, 1814. He graduated at Harvard college in 1831, and spent a year at each of the universities of Göttingen and Berlin, after which he traveled in the south of Europe, chiefly in Italy. On his return to America he studied law, and was admitted to the bar in 1836, but he practiced little. In 1839 he published a novel entitled "Morton's Hope, or the Memoirs of a Young Provincial." In 1840 he was appointed secretary of legation to the American embassy in Russia, and held the post for about eight months, when he resigned and returned to the United States. In 1849 he published "Hercy Mount, a Romance of the Massachusetts Colony." Meanwhile he had contributed various articles to some of the leading reviews. About 1846 he began to collect materials for the history of Holland, writing enough to form a single volume; but, unable to find at home the authorities necessary for the thorough prosecution of the subject, he embarked for Europe with his family in 1851. Dissatisfied with his previous labors, he threw aside all he had written, and began his task anew. In Berlin, Dresden, and the Hague, he passed most of his time during the next five years in the composition of his history, "The Rise of the Dutch Republic" (3 vols. 8vo, London and New York, 1856). It was reprinted in English at Amsterdam, and was translated into Dutch under the supervision of the historian Bakhuizen van den Brink, who prefixed an introductory chapter. A German translation was published at Leipsic and Dresden, and a French translation, with an introduction by Guizot, was published in 1859 in Paris, and another in Brussels in 1859-'60. It was also translated into Russian. In 1860 Mr. Motley published the first two volumes of the second portion of the work, entitled "The History of the United Netherlands from the Death of William the Silent to the Twelve Years' Truce, 1609," and in 1867 it was completed in two additional volumes. The work was published in 1874 by "The Life and Death of John of Barneveld, Advocate of Holland; with a View of the Primary Causes of the Thirty Years' War" (2 vols.). It is understood that Mr. Motley is engaged in writing a "History of the Thirty Years' War." He has been elected a member of various learned societies in Europe and America, among them of the institute of France in place of Mr. W. H. Prescott. In 1860 he received the degree of D. C. L. from the university of Oxford, and that of LL. D. from Harvard college. He has also received the degree of LL. D. from the university of Cambridge, England. In 1861 he published in the London "Times" a paper entitled "Causes of the American Civil War," and in 1868 delivered before the New York historical society an address on "Historic Progress and American Democracy." On Nov. 14, 1861, he was appointed minister to Austria, and resigned in 1867. On the accession of President Grant in 1869 he was appointed minister to England,
but was recalled in November, 1870, when he revisited Holland, and afterward went to England, where he still resides (1875).

**MOTMOT** (*momotus*, Briss.; *priionites*, Ill.), a genus of American fissirostral birds of the family of rollers and subfamily *momotina*. The single genus is characterized by a bill rather long, slightly curved, with compressed sides, hooked and obtuse tip, and lateral margins serrated; wings moderate and rounded, fourth to sixth quills nearly equal and longest; tail lengthened and graduated, with the two middle feathers usually longer than the others; tarsi as long as the middle toe, covered in front with narrow transverse scales; toes unequal, the outer nearly as long as the middle and united at the base as far as the second joint, the inner short and slightly united, the hind short and weak, and the claws compressed and curved; the tongue is long and barbed as in the toucans. The name is derived from the peculiar notes. There are about a dozen species, bold and wild, inhabitants of tropical America and the West Indies, especially in the deep shades of the forests or gloomy recesses of old buildings; they are usually solitary in the daytime, perching with the head drawn between the shoulders; they are most lively at early morning and in the dusk of evening, pursuing insects in short flights; they also eat fruits, lizards, and snakes, which are tossed into the air from the point of the bill and swallowed; they sometimes devour the eggs of other birds. The nest is made in holes of trees or banks of earth. They are said to peck off the barbs from a portion of the stem of the central tail feathers, leaving a rounded feathered surface at the tip. The best known species is the Brazilian motmot (*M. Brasiliensis*, Lath.), about the size of a blackbird, of a deep rich green color, with bluish forehead, violet back of head, and black crown. The movements are awkward on the ground.

**MOTRIL**, a town of Spain, in the province and 36 m. S. by E. of the city of Granada; pop. about 13,000. The streets are in a bad condition. The principal square contains the collegiate church and the town house. Among the other public buildings are chapels which formerly belonged to convents and a handsome church connected with a monastery. The Mediterranean having receded about a mile, the port has been removed to Calahonda, 7 m. E. of the town, and to the roads of Baradero. The principal imports are rice, sugar, coal, and wine, and the exports comprise fruit, oil, wine, and lead. Fish and fruit are especially plentiful. There are many potteries and several sugar and other manufactories.
